where else away from their own mountains. Further north and further inland the number of species that can be successfully grown in the open air is gradually reduced. The climate near London is not particularly favourable for tender evergreens, yet even here upwards of a dozen species can be grown provided some sheltered spot is allotted them. The publication of a plate of one of the most charming of them affords an opportunity of bringing the whole group into notice.

The greatest evils they have to contend with are the dry, cold winds from north and east that are so frequent in the early spring. It is one of the commonplaces of horticulture that a plant will bear a very low temperature in a still air much better than a higher one in a wind, but few plants emphasise its truth more than these Himalayan Rhododendrons. The first requisite, therefore, is a place well sheltered on the north and east sides. Another point to remember in the same connection is that some of them flower early in the year, when frosty nights followed by sunny mornings are frequent, and as the flowers will bear a few degrees of frost without injury provided they can thaw before the rays of the sun strike them, shelter on the eastern side is as necessary to keep off the early rays of the sun as it is to keep off wind. In other matters of cultivation, and in their likes and dislikes, these Rhododendrons are similar to the bulk of the great Heath family. They cannot be successfully grown in a soil that is strongly impregnated with lime, nor in one so poor or gravelly as to be always practically dry during spells of hot weather. A naturally peaty soil is no doubt best suited to them, but a good, fairly stiff loam, improved by mixing peat and decayed leaves, meets their requirements almost as well. Mulching with short manure during the summer helps them greatly, and where seed is not wanted the seed-vessels should be removed immediately the flowers are over. But, of course, these and similar details apply with equal force to all Rhododendrons.

R. ANTHOPOGON.—This is not a very striking or ornamental plant, but it is interesting as a dwarf and perfectly hardy Rhododendron from the high Himalaya. It extends from Nepal to Cashmere at elevations of 9,14,000 feet, and is amongst the last of the woody vegetation that is found at those levels. It grows from 1 foot to 2 feet in height and is of compact growth. The leaves are of a lively green, each about 1½ inches long, and densely covered on the lower surface with scales that ultimately assume a rusty red colour. The flowers are in small terminal clusters, each bloom about 1 inch in diameter and of a dull yellowish white.

R. ARBOREUM.—There is little to be said in favour of this species as a hardy shrub near London, although magnificent specimens are to be seen in Cornwall and South Wales. Five years ago I remember especially well seeing a noble specimen in Colonel Tremayne's garden at Carclew. This was a tree 25 feet or 30 feet (perhaps more) high, with a trunk 4 feet in circumference. Like some other Rhododendrons from the Himalaya, this varies greatly, and in the earlier days several species were made of what are now all united under the one name. There is one set whose leaves are quite silvery and shining beneath, whilst another has the under surface more or less of a rusty red. The flowers vary in colour also, from rosy purple to a rich blood-red. It is the silvery-leaved, pure red form that botanists consider typical, but this unfortunately is not hardy away from the south-west. It has, however, made its influence very apparent in the garden race of Rhododendrons, for most of the true red (as distinguished from the purple) varieties derive their bright colour from this species. It is the varieties of *R. arboreum* whose leaves are reddish beneath that are evidently the

hardest. The only one we grow outside is the variety *Campbellii*, which has this type of foliage and rosy purple flowers. It has a healthy appearance and never suffers from cold, but it grows very slowly and does not flower with freedom. It is of interest as the hardest of the beautiful "arboreum" group.

R. CAMPANULATUM.—In colour this species is not so striking as are some of the others—not so brilliant in colour, for instance, as *fulgens* or *Thomsoni*—but it is as hardy as, and on the whole thrives better than, any of the Himalayan species. It is a wide-spreading bush rarely more than 6 feet to 9 feet high, but nearly always more in diameter than it is in height. Its leaves are covered beneath with a bright rusty red felt-like substance. In the ordinary form the flowers are of a light purple and appear in medium-sized, compact trusses. The flowers are bell-shaped, as the name implies, and are at their best, as a rule, about mid-April. This plant is very variable. At Kew there is a specimen with pure white flowers—a lovely plant—and another whose flowers, although purple, are of a shade that is nearer blue than perhaps any Rhododendron in cultivation. The leaves also vary in shape, and the bracts that appear with the new growths in spring, although usually green, are sometimes as crimson as those of *R. fulgens*. This is one of the older species, having been introduced in 1825.

R. CAMPYLOCARPUM.—The accompanying plate, reproduced from a picture made by Mr. Moon at Kew in May last, gives a charming and characteristic representation of a Rhododendron which has hitherto obtained but scant notice from either artists or horticulturists. It is, nevertheless, one of the loveliest as well as one of the most distinct of its kind. Its greatest merit is in the colour of its flowers, which are of a very pretty shade of pale yellow. The absence from amongst the garden race of Rhododendrons (excluding *Azaleas*) of a kind with yellow flowers has often been commented on and regretted. There are one or two more species in cultivation with flowers of this colour, but *R. campylocarpum* is the only one that can be said to possess the qualities likely to secure its progeny a place among choice Rhododendrons. Considering what has been done by the hybridiser with the red-flowered *R. arboreum*, how much of its glorious colour has been retained and its tenderness eliminated (in such varieties, for instance, as *Michael Waterer*), there seems to be no reason why *R. campylocarpum*, subjected to the same care and skill, should not eventually produce a race with flowers of the much desired colour. At Kew this Rhododendron is a dwarf rounded bush, not more than 3 feet high at present, and of very neat and compact habit. Its leaves are each 2 inches to 3 inches long, of a lustrous dark green above and glaucous beneath. It commences to flower about the beginning of April and lasts well into May. This year the plants were completely covered with bloom, and were conspicuous 200 yards away.

R. CILIATUM.—Where it is suitably placed this dwarf Rhododendron makes a charming bush. In the open air near London I have not seen it more than 3 feet high, but in Cornwall plants twice as high may be seen. The foliage is quite distinct, being of a paler green than that of most Rhododendrons, and densely covered with bristly hairs, especially when the leaves are young. Whilst the flowers remain in the bud state, and even for a short time after they have expanded, they are of a lovely shade of rose, but afterwards they become almost or quite pure white. Although the species itself is rarely seen outside botanic gardens, it is the parent of a group of well-known and valuable hybrids, amongst which are *præcox* and *Rosy Bell*.

R. CINNABARINUM.—There is a very distinct group of Rhododendrons from the Himalaya, the various forms of which were originally known under the three names, *cinnabarinum*, *Roylei*, and *blanfordii-florum*. They are characterised by long-tubed flowers, almost exactly like *Lupagerias* in shape, and which vary in colour and

size, but the differences have not been considered sufficiently marked to justify the retention of the old specific names, especially as intermediate forms occur, so now the name here given is made to include the whole group. The plants attain near London a height of from 6 feet to 8 feet, possibly considerably more in milder districts. The leaves are each from 1½ inches to 3 inches long, glaucous above, especially when young, and ultimately reddish brown beneath. The flowers are each 1½ inches to 2 inches long, of a cinnamon-brown in the type, but frequently tinged with yellow and sometimes with green. It flowers during May and June.

R. FULGENS.—There is plenty of Rhododendrons to be seen in gardens bearing this name, but very few of the true Himalayan species to which it rightly belongs. *R. campanulatum* is the substitute as a rule, the two species being, indeed, scarcely distinguishable in a small state and not in flower. When old, *R. fulgens* appears apt to become rather gaunt in habit: such, at least, is its character at Kew, quite different from the low, compact growth of *R. campanulatum*. With regard to its flowers, it is unrivalled among Rhododendrons hardy in the London district. They are produced towards the end of March in close, rounded trusses, each 3 inches to 4 inches across, and are of a rich blood-red. The leaves are each about 4 inches long and covered beneath with a thick felt, which eventually assumes a warm, rusty red colour. Another ornamental feature is made by the crimson bracts that accompany the young growths in spring. In the Rhododendron dell at Kew—a well-sheltered spot—this species has never suffered during the hardest winters. Its flowers are occasionally damaged by frost, but when fully in bloom and at its best it is one of the most wonderful of hardy shrubs. In the gardens of Cornwall and Wales *R. arboreum* is probably a superior plant, but here, near London, we are denied the privilege of growing the true crimson-flowered form of that species in the open air.

R. GLAUCUM.—This is one of Sir Joseph Hooker's introductions, seeds of it having been sent to Kew by him in 1850. The plants thus raised flowered in April, 1853. This is one of the dwarfier species, rarely growing more than 2 feet in height even on its native mountains, where it lives at altitudes of 10,000 feet to 12,000 feet. The whole plant has a strong, rather acid odour. The leaves are each 2 inches to 4 inches long, of a dark, dull green above and conspicuously glaucous white beneath. The flowers appear at the ends of the shoots in April and May half-a-dozen or so together. Each one is about 1½ inches across and of a deep purplish red. It is a plant of botanical rather than horticultural interest.

R. LINDORUM.—This is a very pretty, distinct, and rather remarkable Rhododendron, suitable for growing in the rock garden, but unfortunately a very rare plant at the present time. According to Sir J. Hooker, it abounds on the lofty interior ranges of the Nepal and Sikkim Himalaya, at from 8000 feet to 16,000 feet above sea-level. It grows from 1 foot to 4 feet high, and has pale glaucous green leaves averaging 1 inch in length. The flowers are few in the cluster; each one is about 1 inch across and distinct among these dwarf species for the unusual length of the stalks, which measure sometimes 2 inches in length. The corolla is flat and spreading and varies a good deal in colour; typically it is a rosy-purple, but sometimes deepens into a murex-purple. Hooker mentions varieties with golden-yellow flowers, and in the variety *chloranthum* they are described as being greenish yellow. I have never seen these yellow-flowered varieties.

R. NIVIMUM.—This species is a very uncommon one in gardens, and it is, indeed, one of those that can best be spared, being more remarkable for its foliage than for its flowers. Its leaves are amongst the largest found in evergreen hardy shrubs, some of the largest being 9 inches long by 3 inches wide. As a rule, however, they are not more than two-thirds that size. When young they are covered on both sur-

faces with a snowy white felt, to which, doubtless, the specific name refers: eventually this felt disappears from the upper surface, but remains on the lower one, turning a pale brown. Considering the size of the leaves and of the plant itself, the flower-trusses are very small. They are usually each some 3 inches to 4 inches in diameter, with the bell-shaped blossoms compactly arranged. The colour is a shade of purplish lilac, very uncommon among Rhododendrons. The species has been grown outside for many years at Kew, and has proved to be one of the hardiest.

R. THOMSON.—Although this species grows and flowers without protection near London, it has not proved itself altogether satisfactory. It seems to require a slightly warmer climate, for in Cornwall there are magnificent specimens. Here its branches often die back without any apparent cause, leaving the plants thin and gaunt, and not abundantly provided with foliage. It requires, even more than the others, a moist, well sheltered nook. The leaves are each 2 inches to 4 inches long, very deep green above, but glaucous beneath. Its flowers appear during April in loose trusses and are of a very rich blood-red. The individual blossom is rather flat and widely expanded, measuring about 3 inches across. A distinct feature of the flower is the large cup-shaped calyx, which measures three-quarters of an inch across. The species has been used by hybridisers, though not to a great extent. Its progeny, of which the brilliantly coloured, early flowering Ascot Brilliant is one, can generally be recognised by their having inherited the large calyx just alluded to. W. J. E.

THE WEEK'S WORK.

FRUIT CULTURE UNDER GLASS.

VINES.—EARLY FORCED HOUSES.—The Vines in the earliest houses should now be quietly going to rest. It is not a good sign when such as these make late growths, yet it is not safe to keep the roots on the dry side so as to perceptibly check this propensity. It is better to pinch out the sappy shoots rather than keep the borders too much on the dry side. If so be the growth has ceased, the partial pruning may be proceeded with, shortening the spur growths to within about 1 foot or so of their length. Do not remove any leaves below this pruning for the present, but endeavour to keep them in as healthy a condition as possible until they are fully matured, syringing if needs be to keep down red spider or thrips, both of which may be troublesome after the hot weather. If the wood does not look sufficiently ripened, keep a little warmth in the pipes with an abundance of ventilation constantly on. Do not let these or any other vineries be overcrowded with plants. Where this is done the houses are not really vineries at all, but plant-houses in which vines are also grown, being only deemed of secondary importance. Let second early and other houses from which the fruit is all cut be moderately pruned—*i.e.*, take out superfluous shoots in the form of laterals so as to admit all the light and air possible both for the ripening of the wood and also of the foliage. The previous hint as to keeping the pipes a little warm will also apply in every case where the wood is not sufficiently ripened. Keep a sharp look out for the slightest trace of mildew upon the shoots or leaves, and even with no fruit upon the Vines do not hesitate to sulphur the pipes in the customary manner. If the germs be there now the possibility of an attack another season upon the bunches will not be at all improbable, even under rational treatment.

LATE HOUSES WITH RIFE FRUIT.—These should now be kept cool, being well ventilated during the day and nearly closed at night, but not quite if air can be safely left on, as the early accumulation of moisture in the morning is soon precipitated upon the berries as the temperature rises. Do not keep any heat in the pipes at night, unless

it be when the weather is damp or the days be cloudy; but rather at such times maintain a little warmth during the day, by which means the atmosphere will be rendered more buoyant. Keep a close watch for any symptoms of decay in the berries, removing such with the greatest possible care. Should there be any shanked berries, let these also be cut out at once. When a few berries have been noted in one bunch, make a point of using it at the first opportunity. If the Grapes have to be packed to send any distance, select those bunches which are the most compact. Should any have to be sent extra long distances at this season, when such Grapes as Alhwick Seedling are ripe, this variety will be found to travel very well, keeping also in good condition when cut for some few days.

LATEST HOUSES.—If by any chance the crop in these is not by this time fairly well advanced in the colouring stage, a steady and genial warmth should be kept in the pipes, so that 65° at least is recorded at nightfall and a few degrees higher if possible. Ventilate these freely during the day, and do not close until the sun has receded sufficiently not to make any perceptible rise in the temperature. All late Grapes should under good management be fully coloured by the end of this month, but it must not be inferred that they are then fit for use. Such kinds as Lady Downe's Seedling, Gros Guillaume, Mrs. Pince, and Gros Colman all improve in flavour by hanging for even months later. Where Black Hamburg, Muscat Hamburg, and Madresfield Court are grown no other black Grape should be cut as long as the supply of these kinds is not exhausted. Be cautious when dealing with Muscats not to fire too much when the fruit is getting ripe, for if this be then continued there is the possibility of shrivelling taking place. Lady Downe's, be it noted, is also liable to this same failing if fired too long and continuously. Do not allow the foliage to become too dense and thick in these late houses, otherwise there will be an accumulation of moisture, which may occasion mischief. Should there be any over-abundance of laterals, it will be advisable to remove such at a few short intervals, reducing all of these steadily down until none but ripened wood is left by the end of the current month. If inside borders have to be dealt with, see that they are now quite safe as regards moisture, watering at once if needs be rather than in a few weeks' time, applying also a mulch of clean litter, which will act beneficially in two ways, *viz.*, by preventing the surface soil from becoming too dry and also by preventing any dust arising to settle upon the bunches.

YOUNG VINES AND THOSE NEWLY PLANTED THIS SEASON.—The former of these should not now be encouraged to continue in active growth. By means of more liberal ventilation this tendency may be checked without cooling the houses down too rapidly. Still make it a practice to syringe these young Vines daily, and still bear in mind the previous remarks about the spider, which for the sake of distinguishing it from the red kind we will call the white, which is appropriate, as these very minute creatures are apparently white. It is a most insidious pest and may very easily be detected by the leaves dropping from the points of the shoots, while those still hanging on assume a pale lustrous brown shade. Note soot as the remedy for this pest, as alluded to on page 43 of the present volume (July 16). Where the Vines of two or three years' growth have become dense in shoots, not being as yet treated in an orthodox fashion, some of the sappy wood may be safely removed. This will not occur so much, however, where the Vines have been treated as suggested by allowing the lateral shoots to hang down indiscriminately below the wires, by which means any disposition to make a late growth will be held in check to some extent. Younger Vines, as those of this year's planting, may possibly stand in need of warmth still to complete a tolerably good growth for the first season. Sometimes these are not planted any too early, hence the need of making up for loss of time in some

small degree. See that these young Vines of varied stages do not suffer for want of water: there is just the possibility of this happening, as we know by past experience in made-up borders that are well drained.

VINES IN POTS FOR EARLY FORCING.—These ought now to be well matured, the wood hard, and of a nutty brown tint, with the dormant buds well swelled up and the foliage of the main rods thick and leathery, already assuming that tint one likes to see. Do not allow anything beyond the first lateral to remain any longer; these even may be cut away close to the main stem in a few weeks' time. Preferably the place to finally ripen these canes is near the glass in well-ventilated houses; failing this, let them be exposed outside in the sunniest and warmest position possible, but do not in either case allow these young Vines to become dry at the roots, protecting the pots from getting hot and dry by means of short litter. Young Vines of this season's raising should now be cooled down so as to check growth in due course.

OUTSIDE BORDERS.—With the long continuance of drought in some parts of the country, it may be necessary to still water these borders, more especially if they happen to be raised ones, or otherwise, such as if of shallow formation. Do not assume that because the crop is all cut no watering is needed; quite the reverse is the case, for, whilst watering such as these now, an excellent opportunity is afforded of giving a dressing of artificial manure, if such be required. It will be productive of better results than if left until the spring wherever forcing is practised. If applied now, it should be lightly pricked into the surface soil, the border afterwards being well watered. In no case is a heavy mulching desirable now; rather let the sun's influence work its beneficial course upon the soil. Do not, unless quite compelled to do so, water borders with ripe Grapes upon the Vines now. HORTUS.

KITCHEN GARDEN.

EARLY MUSHROOMS.—A full supply of Mushrooms may be needed in the early autumn, and in a previous note I advised the cleansing of the Mushroom house, as woodlice are difficult to get rid of when the beds are made, so that a thorough cleansing previous to the making of new beds is important. There may be a difficulty in the supply of manure, and my advice is to make up small beds in preference to larger ones. Materials must be collected regularly for the making of beds, and, if there is room, no one will make a mistake in making a bed every month or six weeks, as, though beds last a longer time than the period named, much depends upon the house, as if the latter is at all warm the beds are sooner over. The best Mushroom houses are underground, as here there is a regular temperature. Artificial heat is not needed, as the produce is more succulent and the season longer. Now is a good time to get a fresh supply of spawn, and, though the last season's supply may be of good quality, I prefer to mix a portion of new spawn and thus avoid failures. In the preparation of materials it is well at this season of the year to make smaller heaps of manure when drying, as large quantities heat so rapidly that it may be spoiled before it is observed. Manure if overheated prevents the spawn running freely. The material needs turning over more frequently now than in the winter. I would at this season of the year dispense entirely with fire-heat, as much better results will follow a low, even temperature. Though I am in favour of spawning the beds before the manure loses too much warmth, it is quite safe when below 100° and the temperature is falling if the beds are shallow as advised above. In covering the surface it is well to use soil of an adhesive nature, as the firmer the surface the better the spawn runs. Beds made on the floor are far the best till the nights are cooler, and the house may be kept at a low, even temperature. More moisture may be given in houses at the back of fruit houses, as these dry sooner than those underground. If the spawn is very

dry or at all old it is well to soak it for a few hours or place it on the top of the beds two days before using. By so doing there will be a considerable saving of time, as the spawn will start much sooner.

SPINACH.—In the southern part of the country I always make a liberal sowing of Spinach in the latter part of August or early in September, as though this date would be full late in the north in heavy soil, it often fills in a void, as if the spring be a late one this late sowing lasts well without running to seed before the spring-sown turns in. Spinach to do well, I find, does not need coddling. One very often sees a good crop in open fields exposed to all weathers. This being dwarf and having a thick leafage will be unhurt, whereas in a sheltered garden with a soft growth the produce is poor. With field culture one may vary the soil and position. Few vegetables need change of soil more than Spinach, as it is bound to fail if wireworm and other pests are rampant. I find more difficulty with winter Spinach sown at the usual time early in August than at any other period of the year. Almost anyone can grow spring-sown Spinach, as the plants are so short a time in the soil, the growing conditions, too, being more favourable. Spinach sown now will be on the land quite eight months, and the soil must be prepared to make sure of a crop. Anyone who may have a recently-made garden will think it just the thing for this crop, but if the land is turf dug in, beware of wireworm, as the old turf is the home of the pest. Winter Spinach does not need large quantities of manure. I am obliged to give land for such crops as this dressings of gaslime, which should, if quite fresh, be spread on the surface for a few days and be finely broken up. In a light soil it is essential to have a firm root-hold, as then growth is sturdier. I tread or roll recently dug land previous to sowing. I also give ample space between the rows; 18 inches is none too much. For present sowing Carter or a good strain of Victoria is the best. I do not like the old prickly form; it runs too quickly in the early spring. The large Viroday is also an excellent winter Spinach. At one time the round-leaved varieties were thought to be less hardy than others, but such is not the case. The earlier-sown Spinach should now be well thinned out to give large leaves for an early autumn supply.

CARDOONS.—This year Cardoons have been a difficult crop to keep going, and in light soil I fear, unless the trenches were flooded at least once a week, the plants in many cases will be of little value. The Cardoon unless well attended to quickly fails, and even in seasons when we get an ordinary rainfall the plants do not thrive unless well fed and watered. Plants in full growth will take unlimited supplies of liquid manure; indeed, twice a week will be none too much. Failing liquid, such aids as guano, fish manure, and light dressings of nitrate of soda will be necessary. It will be well to go over the plants before feeding, removing any useless or sucker growths, and the long leaf-stalks if needed may be given light supports to prevent breakage. I do not advise earthing up yet unless very early produce is needed. Far better secure a full growth before blanching. Plants that have run are of little use, and may be thrown away to give others room.

CELERYAC.—This vegetable is not grown nearly so much as it should be. At this season the plants to be good will need extra attention. Moisture and food will now be necessary to secure large roots. In hot, dry weather and in light soil Celeryac makes poor progress unless given assistance. In such land I find it best grown in shallow trenches, somewhat like Celery. Celeryac should never be dry in the growing season, and there need be no fear of giving excess of food in the shape of liquid manure if not of too strong a nature. The best plants I ever grew were in land I could irrigate weekly, and the quality was far superior to that grown in dry soil. Much the same food may be given here as advised for Cardoons if water be given freely afterwards. It will be well to go over the rows, removing sucker growths, as these rob the plants.

LATE PEAS.—In light porous soils this is a difficult crop to keep going in such seasons as we have had this summer. Heat and drought are the greatest evils, and when we have a genial rainfall mildew often takes possession of the plants and growth ceases. The dwarfier section, such as are sown for earliest supplies, are more reliable than the taller ones, such as No Plus Ultra and British Queen, though these latter in the northern parts of the country, with a cooler atmosphere and more moisture, are difficult to beat, as they crop so well and the quality cannot be beaten. With little rainfall, mulching in light soils has been a necessity, and I find the plant is much stronger when waterings can be given late in the day, as if treated thus the haulm makes a clean growth, free of spider, and is much stronger. Liquid manure given once a week will do much to keep the crop going, and should mildew be troublesome, I find watering overhead with sulphur and fresh lime will arrest its progress. Any varieties which were sown too thick for very late supplies will benefit by being thinned if the weather is showery, as if too thick the haulm gets mildewed badly, and if once this gains headway the crop is lost. The dwarf kinds, such as May Queen and Chelsea Gem, are best for latest supplies.

DWARF BEANS.—Those who have frames to spare may turn them to good account by sowing one of the dwarfest kinds for a supply after those in the open air are past. Those, if given liberal treatment, may be kept going till the autumn is well advanced. I sow Syon House, Mohawk, and No Plus Ultra for the latest crop, but this season I am trying Early Favourite, a dwarf-growing kind with a large pod. The soil must be fairly rich, as the season of growth is short. If the frames at the present moment are not vacant, I have sown in pots and planted out the third week in September with every success. For latest supplies it is well to have a little artificial heat, as then the pods set more freely in dull, wet weather. Hard forcing should not be resorted to, as the haulm will be stronger grown under more natural conditions. Plants sown on south borders with a view to late cropping will need supplies of food and moisture to ward off attacks of red spider. I water overhead freely late in the day. S. M.

STOVE AND GREENHOUSE.

ERYTHRINA CRISTA-GALLI.

Few plants are so bright and showy as the Coral Root, as this has been called. When grown in pots and brought along steadily, the stems on medium-sized plants attain to a height of about 30 inches, and in this state it is charming for conservatory decoration, being almost as showy as Cannas, and much prettier in the foliage. The flowers appear in terminal racemes, and are bright red and very singular in shape. The stems are herbaceous, leafy all the way up, and more or less covered with small prickles. These spring from a large bole or root-stock, and where propagation in quantity is desired, a few of these may be placed in a gentle warmth in early spring. The shoots soon appear above ground, and when an inch or two of growth is made they may be taken off low down and dibbled in around the edges of 6-inch pots. With a gentle bottom heat they soon strike in sandy compost, and may be potted on and grown as well as possible during the first season, when they make nice strong plants for the next. Old plants may be grown with ease in quite a cool greenhouse. If received as dry roots they must be moistened a little, but not kept wet until the growths have made considerable progress, when an increased supply will be necessary. It flowers at various times, according to when the plants are started, and a succession may be kept up from late in May until September by bringing them on a few at a time as required. After the flowers are over, the foliage soon begins to lose colour, and drops. As

this occurs, gradually diminish the water supply again and keep the plants in a light, cool position. They may be placed outside with advantage while going to rest, and allowed almost to take care of themselves.

In sheltered gardens this *Erythrina* is sometimes planted out, and when established it flowers abundantly in hot, dry seasons, looking especially well if backed up by suitable greenery. In winter a good thickness of dry leaves should be placed over the root stocks, for the root stocks may be taken up and stored in cool greenhouses, though this frequent disturbance is not conducive to free growth or flowering. In Hyde Park, not far from the Stanhope Gate, there is a nice bed of it, and when massed like this it makes a very fine show for a considerable time.

Utricularia montana.—The flowers of this species are similar in shape to those of *U. Endresi*, but they are pure white on the blade with a yellow centre. It is rather stronger-growing if anything than its rosy coloured compeer and equally beautiful when well grown and flowered. After being open some time the flowers fade to a rosy tinge. It is best grown in baskets suspended from the roof of a moist, warm house, the compost consisting of Sphagnum and peat with abundance of charcoal or broken crocks both for drainage and mixing with the compost. It is a very thirsty subject, and must never be allowed to suffer from want of water. Even in winter it must not be dried.

Aristolochia tricaudata.—This is a pretty species of Birthwort, far more worthy of cultivation than many that are more grown. The plant is of medium habit, with leaves each about 6 inches long and light green. The flowers at first sight remind one of those of a large *Masdevallia* of the Chimara section, though when looking at it closely there is none of the marvellous colouring as seen in the *Orchid*, in fact, being a dark purple-brown. In a large stove or plant house where there are pillars or tie bars to cover, this plant may well have a place. The foliage will always be ornamental, and the three-tailed flowers that suggested the specific name would have a very distinct and effective appearance. It is easily grown in a fairly light and rich description of compost, but may be kept a little pinched for pot room unless a lot of space is required to be covered. It is a native of Mexico, and was introduced about 1866.

Lagerstromia indica.—On a recent visit to Kew two fine plants of this in full flower in the Mexican house seemed to attract a greater share of attention than anything else there. It forms a freely-branched tree-like shrub that reaches a height of 6 feet to 10 feet, and is clothed with small deep green ovate leaves. The flowers, which are of a particularly attractive shade of rich pink, are borne in terminal panicles, and so freely are they produced that the entire plant is quite a mass of bloom. The petals being very much crisped, the clusters of flowers have a peculiarly loose and uncommon appearance. Close by was a fine bush of the double pink *Oleander*, also in full flower, thus showing the merits of another good but neglected plant. Both of these subjects may be grown in large pots or tubs, as the Orange is sometimes treated, and with a little care and attention will flower well every year. In each case a thorough ripening of the wood is necessary to a good display of bloom.—H. P.

Calceolaria alba.—There is a group of good-flowering examples of this *Calceolaria* in the temperate house at Kew. The plants in question are neat, bushy specimens, about 18 inches high, clothed with their peculiarly narrow serrate leaves, while the pure white blossoms are plentifully borne on the upper parts of the shoots. *Calceolaria alba* was introduced from China in 1844, but it appears to have been soon lost. A few years ago, however, it was again brought to this country and soon obtained many admirers. A coloured plate of it was given in THE GARDEN, January 23 of last year. This *Calceolaria* is less

robust in constitution than many other species, yet at the same time it is not at all a difficult subject to cultivate successfully. Cuttings of the half-ripened shoots may be struck without difficulty, while seeds may also at times be obtained. A mixture of loam and peat or well-decayed leaf mould with sand will suit it well. Like many other plants from the same region, it succeeds best in a fairly cool, moist atmosphere, and it can be well grown in a cold frame where not too much exposed to the sun.—H. P.

Acalypha Macfeeana.—When well grown this is one of the finest plants we have for decoration, the large leaves being of a rich, almost crimson, hue. It is not difficult to grow, but is much inclined to run out of character, the colours being imperfect and the leaves much lacerated and contorted. I think this latter defect is caused to some extent by growing it in too high a temperature, for I find plants grown this season in an intermediate house have retained the broad heart-shaped leaves and have also coloured well. There is always some variation in colour. Cuttings should be selected from the best coloured, strong shoots; they root freely in the ordinary propagating pit and soon make good plants. They should be potted in a good rough compost, consisting chiefly of loam and manure, and plenty of drainage. Like many other fine-foliaged plants, they delight in sunshine, and it is only when well exposed that the rich crimson hue is fully developed. Being of rapid growth, it is only when a succession of young plants is kept up by propagating at intervals during the year that useful-sized plants can be always at hand.—A.

Crassulas.—Presuming that "Reader" refers to *C. coccinea* which has been seen in Covent Garden in such fine form this season, it is now too late to propagate for flowering next year, but cuttings put in now will make good plants for growing on to flower the following season. They will root freely in any light sandy soil. After taking them off, a few bottom leaves should be removed and the cuttings laid on a dry shelf for a time, or until all moisture at the base has dried up. They may then be put into pots or pans and kept quite dry for a few days. In fact, they require very little water until well established. In potting them on, a good rich loamy compost should be used. The plants should be grown on in a greenhouse temperature and fully exposed to the sun. During the summer they do better out of doors or in a pit where they can be protected from heavy rains. Where strong cuttings can be had early in the spring they will flower the following summer, and if about three or four are grown together in the same pot they make a good show. There are several varieties; the one mostly grown for market now is what I first knew as Phoenix, the true *coccinea* being of dwarf habit and not so deep in colour. There are also some hybrid varieties sent out by V. Lemoine a few years ago; these are of dwarf habit and branch out, forming bushy, compact plants and flower very freely. The colours vary from almost pure white to deep red. They come into flower earlier in the season than *coccinea*, and are well worthy of attention.—A.

NOTES AND QUESTIONS.—STOVE.

Canna aurea.—Among the innumerable varieties of large-flowering Cannas that we now have in our gardens are many that closely resemble each other, so that a rigid selection is absolutely necessary. The variety *aurea*, above mentioned, stands out as quite distinct from most of its associates, the flowers being of a clear self-yellow, very different from the spotted, banded, and edged flowers of the other kinds, and the plain reds and scarlets, of which we have so many. The foliage of the variety *aurea* is green, without any tinge of bronze.—H. P.

Saintpaulia ionantha.—This pretty little plant should eventually become as popular as the hybrids of *Streptocarpus*. It is very elegant, and I saw it used with good effect the other day at Culford, Bury St. Edmunds, plants in 6 inch pots being arranged near the edges of the stages

in a cool house with small Ferns and fine-foliaged plants. It requires careful culture in the earlier stages, but when once strong and well established it gives little trouble and flowers for months on end.—H. R.

Anthurium Lawrenceæ.—I lately noted an immense specimen of this rare and lovely *Anthurium* in flower. I did not measure the spathes, but they must have been at least 6 inches across. It is not only the size that appeals to me; it is the lovely purity of the white, so different from the dirty whites and dull purples or reds so frequently exhibited. This was one of the very finest of the fine group staged at the Drill Hall early in the present year by Sir Trevor Lawrence. It is of the true *Andreamum* shape, and I think the finest variety at present in cultivation.

Calceolaria Burbidgei.—*Calceolaria* Burbidgei was raised nearly twenty years ago in the College Botanic Garden, Dublin, by fertilising the flowers of the distinct *C. dellexa*, or *fuchsiofolia*, with pollen from the strong-growing *C. Pavoni*.

Lilium giganteum in Mr. J. R. M. Camm's garden at Burnham Grange, Bournemouth.

Both species are natives of Peru. The hybrid thus obtained is a vigorous-growing plant, that if planted out or grown in a large pot will form quite a bush 6 feet or more in height, that during the latter part of the summer and well on into the autumn will yield considerable numbers of its pale yellow blossoms. Some fine plants of this *Calceolaria* 6 feet high or thereabouts are very attractive just now in No. 4 greenhouse at Kew.—T.

Begonia coccinea.—This is not at all an uncommon *Begonia* in gardens, but unless liberally treated it is not seen at its best, for if confined in pots and grown in a partially shaded structure, though it may flower, the clusters are not so large, nor the blossoms so brightly coloured, as under different treatment. It occupies a place among the giants of the genus, as if planted out in a warm greenhouse it will reach a height of 6 feet or more, and the flowers that are produced in large drooping clusters are freely borne. They are of a brilliant coral red tint and remain in beauty a considerable time. It is well adapted for clothing the sunny end of a glass structure,

and in this way is very effective just now in No. 4 greenhouse at Kew. This *Begonia* was introduced from Brazil in 1841, and was figured in the *Botanical Magazine* as *Begonia coccinea*, but it is far more frequently met with in gardens under the specific name of *corallina*. Like most of the other members of the genus, it is readily struck from cuttings, and, if planted out, needs a well-drained border and a pretty good soil of a somewhat rough nature.—H. P.

FLOWER GARDEN.

LILIUM GIGANTEUM.

I SEND you a photograph of a spike of this Lily grown in my garden. It was over 7 feet high and had fourteen blooms of the most perfect form. It was a wonderful picture whilst it lasted, but owing to the great heat it only lasted nine days. It was from a bulb I purchased last year. The aspect was south-east and the soil ordinary garden mould. My experience of these bulbs is that the flowering exhausts the bulb so much that it never flowers again.

JOHN B. M. CAMM.

Burnham Grange, Bournemouth.

TOO MANY CARNATIONS.

THE love of novelty is now, and has always been such, that our "intelligent horticulturists" take advantage of the passion and continually raise for us novelties, and in this case we have too many of them. They are brought out wholly in the raiser's interest, so that he may charge a high price for what is really no better than the old things that were sent out years before. If anybody takes the novelties sent out by the florist raisers of Carnations for the last ten years, not one in twenty will be found fit for a place in the open air, which, after all, is the only true test. If these things are raised for the people who show them, then it is a question of a very few who ring the changes and take the prizes. The flowers with the heads cut off and stuck on a board are wholly different in character from those one wants for the open air. No fair trial of their endurance or fitness for the open air is made. If we visit the gardens of the most popular raisers of the present day, we find the plants carefully looked after in good greenhouses, and much attention given to the raising of seedlings for the sake of novelties, but no evidence of any fair trial of their fitness for the open air. Shows are no guide whatever in the matter; on the contrary, they have done infinite harm by preventing us from finding out that the really good Carnations are those that have no points whatever for the show bench men, those simple and often splendid in colour, hardy and free kinds. Where general effect, purity and distinctness of colour are everything, the results which the imbecile rules of the florists lead to are nothing but feeble, striped plants, pretty to look at in the hand, but quite ineffective out of doors, and very often such that one cannot increase them freely or get any fine, healthy growth out of them.

What are we to do if we seek the beauty of this plant for the flower garden and for the house? Good outdoor Carnations are among the very best flowers for cutting for the house, and they come in at a time when flowers are not very varied, and when the greater number of early summer hardy flowers are past. The best way is to select and save the best of the approved kinds for outdoor work, and those that thrive the best with us; for even these plants have peculiarities, some being almost perennials in certain

soils, while some make grass early, and easily keep on from year to year, and others, if they bloom well, make very little. What we call good are such as Alice Neumann, Murillo, and among whites Alice; and for light soils the excellent Countess of Paris, Robinson Suisse, or any kinds, especially those that have a continuous habit of flowering long into the autumn. It would be better to raise a good batch of seed every year and depend on the result than buy with the hope of succeeding out of doors with the new kinds that are sent out by the florists, who, of course, claim for themselves the only right to lay down rules in that matter, with the effect of keeping the culture of this fine plant in a groove, and that a bad one. Among Carnations that we have found constant and good in the open air are Countess of Paris, Carolus Duran, Mme. Roland, Murillo, M. Roussel, M. Bergendi, Ketton Rose, Purple Emperor, Mrs. Reynolds-Hole, Mary Morris, Alice and George Maquay.

As to certain colours, whole groups of colour are, we think, perfectly useless on many cold soils and districts. For example, the yellows are rarely worth looking at out of doors, no matter how many we may buy and try. Even the very best, like Germania, have none of the brightness of colour and vigour of growth of the more naturally coloured Carnations, like the reds, pinks, and whites. The florist's kinds also, which have yellow as a base, are rarely worth growing as a group in almost any soil out of doors. The Malmaison, a purely greenhouse Carnation, has been used by the recent raisers too much, giving us the monstrous form, splitting habit, and delicate constitution which make them quite useless in the open air.—*Field*.

FLOWER GARDEN NOTES.

BEDDING PLANTS.—The much-maligned Geranium has done remarkably well this year, and is in variety among the brightest things in the flower garden. Always leaning much more to the side of hardy than tender plants, I have yet often noted that where formal beds of small size exist in quantity it is found desirable to utilise tender plants, and of these, Geraniums like Turtle's Surprise, Golden Harry Hieover and Chelsea Gem, make a brave show. The first-named is of a rich glowing colour, and being double the flower is well retained. Stronger varieties will be found in Henry Jacoby, Lucius, Amaranth and Flower of Spring. One or two beds of Raspail will be found useful. If planted in a fairly holding soil, trusses of great size and substance are produced that are sometimes very acceptable for cutting. Amaranth mentioned above is a good dark pink kind. If lighter shades are required, they will be furnished by Constance or Beekwith's Pink. The old Manglesi holds its own as a variegated trailer, and helps to make charming beds with occasional dot plants of a strong-growing dark Heliotrope, that throws a very large truss. Always on the look out for flowers that can be used in a cut state, I generally plant one or two beds of the scented-leaved section, and about the best are the finely-cut Filicefolium, the small-leaved peppermint-scented and Lady Plymouth. Writing of Geraniums reminds me to note with them Marguerites, because large plants of both the small and large-flowered varieties never show to better advantage than when surrounded by a carpet of scarlet, crimson or pink zonals. The large-flowered kinds, both white and primrose, are this year, at least in this neighbourhood, badly attacked by maggot. Plants are so rapidly and completely disfigured by this pest where it is locally troublesome as to render it advisable to discard them in favour of the small-flowered, small-leaved variety, unless time can be spared for a regular dewing over of the foliage with some insecticide to render it distasteful to the fly. In yellow shades under 2 feet in height we have nothing brighter or better at present, and with, too, the promise of a long continued display, than the two annuals, Chrysanthemum Golden Button and Marigold Legion of Honour, and I can recommend them to

the notice of all who want a profusion of flower in these shades, and that at a minimum of expense and labour. The chief point is to sow fairly early and prick off quickly to secure nice sturdy plants. Both are capital dry-weather flowers. They do not seem to suffer from protracted drought if the borders or beds destined for their reception were well done. Small beds filled with fibrous Begonia Crimson Gem and a good dwarf Ageratum are now looking remarkably well. The above is, I think, the best of this type of Begonias for outdoor work, and it shows off to great advantage against a white carpet or flowers that run in the lighter shades of blue. Those with green foliage and pale pink flowers are pretty enough in their way, but they are not sufficiently distinct to associate well with other things. The dwarf Ageratum noted above is a very distinct variety, only about 3 inches high, of trailing habit, and a perfect mass of large rather dark flowers. It possesses the advantage of being fairly hardy, standing slight frosts with impunity, and is often flowering freely when circumstances necessitate its removal. Large plants of a dark Heliotrope are very free, the individual trusses of extra size. As a carpet for this there is nothing better than the old Manglesi Geranium. The older Fuchsias hold their own for outdoor work, General Roberts, Mme. Cornelissen, Rose of Castile and Mrs. Marshall being among the best. There was a variety labelled Annette grown some years ago in one of the London parks that I cannot find catalogued. The flowers, if my memory serves me rightly, had scarlet reflexed sepals and a large pale lavender corolla. The plants were almost perfect in shape, and the flowers, if possible, produced in greater profusion than on any of the others named. Specimen Fuchsias should never be crowded with other things, that is if they are employed in mixtures. They should have a dwarf carpet around them some 18 inches in width, so that the outline can be clearly seen right away from summit to base.

E. B.

Canna Paul Bert.—Since the numerous large-flowering varieties of Canna have become so popular, they are largely used not only for greenhouse and conservatory decoration, but also for the flower garden, and grand masses of them are to be met with in many of our parks and gardens. Some of those that are among the finest under glass are, however, by no means the best for planting out of doors, the conditions being so very different. A particularly good variety for outdoors is the above-mentioned Paul Bert, one of the many forms for which we are indebted to M. Crozy, of Lyons. This, which is of particularly sturdy growth, has good massive bronzy-tinted foliage, the stems and edges of the leaves being of a deeper hue, while the flowers, which are borne in good erect spikes, are large, the fine broad petals being of a bright red, with a suspicion of salmon. This variety is well worth growing for its foliage alone, but when a mass of its handsome leaves is crowned with numerous spikes of showy blossoms it is, of course, additionally attractive. It is not so tall-growing as many of the others, reaching, as it does in a general way, a height of 4 feet to 5 feet.—*H. P.*

Alonsoa Warscewiczii compacta.—In addition to the above being a useful annual for growing in masses in mixed borders, it also forms a fine subject for filling beds with, and as such deserves to be more widely known. I have used it this season with great success, and its brilliant orange-scarlet flowers have elicited admiration from all who have seen it. It has a compact habit of growth, and is not weedy-looking, which drawback prevents so many annuals being employed in this way. If planted from 9 inches to 1 foot apart the plants quickly cover the ground and form a fine mass, blossoming with the greatest profusion throughout the summer and autumn. The best way to raise a stock of plants is to sow seed in gentle heat at the end of March, and to either prick out the required number into boxes or in a frame on a mild hot-

bed, planting them out eventually about the middle of May. In colder parts of the country planting would no doubt have to be delayed until June. A great many plants can be raised from a threepenny packet of seed, so that no one can raise any objection to growing it on the score of its being costly.—*A. W.*

PROPAGATING TUFTED PANSIES.

The next five or six weeks should be a busy time with the propagation of these useful hardy plants. In those cases where autumn planting has been decided upon cuttings should have been put in some weeks ago; but at the moment the grower's chief concern should be that of getting the old plants in a condition to provide an abundance of cuttings of a desirable kind. It is not always possible to cut back a number of plants which occupy a prominent position in the flower garden, and on this account if a piece of ground can be set aside for planting the old stools, these may be cut back during the summer and provide an enormous quantity of cuttings during the propagating season. Of course it is possible to remove a goodly number of young growths from the plants in full blossom, and where cuttings of the Tufted Pansies are inserted during July and early August for autumn planting, recourse to this method is often bad. This latter method has the advantage of keeping up a continuous display in the garden, and if batches of new shoots are detached from time to time, it is surprising what a quantity of new stock may be raised for planting out in their permanent quarters during October. Old plants treated in the manner already prescribed are distinctly better than other means of providing cuttings. Such plants produce a compact mass of fresh green growth, and if the proper time be chosen for the selection of the cuttings, they may be detached quite easily and about 2 inches to 3 inches long. Cuttings developed in this way invariably root readily, and even at this season it is possible to raise a batch of plants for October planting by a selection from the stock plants already mentioned. It is only courting failure to make cuttings of old stem growths, as these are generally hollow, and although looking fairly fresh and green for some little time after they are inserted in the cutting-bed, very few indeed ever survive, and even then they rarely give satisfactory results. Where the stock is scarce or the raiser of a good seedling sort is anxious to perpetuate as much as he can of the variety, stem cuttings are sometimes inserted, and with great care may perhaps make plants, but as a general rule it should be discouraged.

A capital position for a cutting-bed, say during July and August, is in a border with a northern or an eastern aspect, the cooler conditions prevailing in these positions ensuring their well-being during these warm months. Equally good results may be had if a position can be obtained where the friendly shade of a hedge or small shrubs, &c., will shelter the cuttings from the strong rays of the sun, and where the latter may filter through the foliage without scorching them. In this position, and if the soil be kept in a fairly moist condition, and the cuttings occasionally sprinkled overhead with a fine rosed can, plants may be had in a few weeks. In my own case the ordinary garden soil is deeply dug and broken up, and with this, equal parts of loam, leaf mould, rotten manure and coarse sand or road grit are mixed and levelled to the depth of about 6 inches. Over this again, to the depth of say 3 inches, a layer of the same compost, but this time passed through a sieve with a half-inch mesh, is evenly arranged. The bed should then be rendered somewhat firm. This is then carefully watered an hour or two before the cuttings are put in. It will thus be seen that the cutting bed is some 8 inches or 9 inches above the level of the garden; the advantage of this is seen later in the season, when during the excessive wet of autumn and in such a cool position the ordinary garden level would not be conducive to the welfare of the young plants

Providing plants for spring planting from the present time and until October may be safely done. Even for this work, frames, &c., may be dispensed with, and only in low, damp situations, or where the position is exposed to cold winds, is it necessary to use them. There is a difference, however, in the position of the cutting-bed for this later propagation, and in this case a south or south-western aspect is selected. The compost is prepared as before, but before this is arranged a framework of 10-inch boards cut in lengths to suit the needs of the grower—in my own case 10 feet by 4 feet—and this raised a couple of inches from the garden level, is filled in and levelled down, leaving some 3 inches to 4 inches of board for protection from cutting winds, and also in the case of long periods of frost, providing a rest for laths or anything of that kind in which to place frame-lights, mats or any protection. With reference to this latter question, in my own case only on one occasion has it been necessary to give protection in this way, and that was during the severe weather of the winter of 1894 and 1895. My experience of plants raised in the hardy manner here referred to is that, although the plants in the spring do not present so fine an appearance as those raised in frames, &c., there are so many shoots in the embryo stage, that after being planted a week or two the soil simply bristles with a large number of growths which were hidden before. These plants, too, soon pass those accorded more kindly treatment in frames and planted out at the same time. When inserting the cuttings, the distance between each one should be about 2½ inches, and 3 inches between each row. This should be ample in most instances, and in the cases of the slower growing sorts, such as Blue Gown and several of the Violetta type, it may be half an inch less each way. Too much emphasis cannot be laid upon the importance of pressing the soil firmly at the base of each cutting, as should they be pressed at the neck of the cutting, the chances are they will "hang," and consequently wither and lie. In cold and unfavourable situations, also in and around large towns, where in the latter case the fogs, heavily charged with sulphur, so frequently cause the cuttings to die off, the frames and cold pits are indispensable, but most persons interested in this increasingly valuable hardy plant would be glad to use their frames for other purposes, could they dispense with them for the Tufted Pansies.

With so many new introductions each season and the acquisition of some lovely selfs from time to time, it would be wise when making a selection to confine oneself to the best of these, as their value for massing in the hardy border is so much greater than when edged and fancy sorts are used. D. B. CRANE.

Highgate.

NOTES AND QUESTIONS.—FLOWER.

Gentiana verna.—I am surprised to see it stated by one of your correspondents, whose letters I always read with great interest, that *Gentiana verna* dies off after a few years, as with me it takes a few years to become established, and then grows and flowers well.—E. D'O., *Bray, Co. Wicklow.*

A white Thistle.—In THE GARDEN of August 13, p. 129, "V. B." asks as to there being a white Thistle. One of our commonest desert plants at Alexandria, flowering in May and June, is a Globe Thistle (*Echinops spinosus*) with heads of pure white flowers as large as a tennis ball. It is a very thorny perennial, of decumbent habit, about a yard or more in length.—R. M. B.

Carnation layering.—Why the common practice of cutting back the points of the leaves on layered shoots should exist I have never been able to understand. It is particularly common practice amongst market growers, who seem to be guided in the practice solely by tradition. Probably no one who practises it could give a tangible reason for doing so. The obvious moral is that the greater the leafage area the more rapidly will sap be generated to create callusing.—A. D.

Carnation Germania.—Although this fine yellow has been referred to as not being satisfactory in

the open air, it has been very fine in a big bed at Maiden Erleigh, where just recently I saw it growing in very considerable quantity. Mr. Turton prepares his ground for Carnations by trenching and manuring, then, because the position is rather cold, planting out in the spring. The result is the production in numerous varieties, and especially some fine seedlings of strong, robust growth and flowers in great abundance. So treated *Germania* was very fine indeed, giving an abundance of beautiful flowers.—A. D.

Carnation Trentham Rose.—This is a variety raised by Mr. P. Blair, of Trentham Gardens, and a good bunch of it was exhibited recently at Shrewsbury, where it obtained a certificate of merit. Whilst very nearly of the same rosy shade as is the well-known Raby Castle, it is so far superior that, whilst remarkably free, the calyx does not in any case split, thus preserving good form, and the edges of the petals are comparatively smooth. Such a variety, having a good, stout constitution, should make a capital addition to our border varieties, and help to eliminate the loose, ragged flowers far too often seen, and of which we want none.—A. D.

YUCCAS AND ACANTHUS.

In the accompanying illustration we are afforded proof of the decorative value of such subjects as bear striking spires of flower. As may be

Group of *Yuccas* and *Acanthus* on the west side of Ojington House, Worthing. From a photograph by Miss Gaisford.

seen, the effect produced when these are planted in the immediate neighbourhood of the house is pleasing, since it at once banishes that sense of formality so often observable in such situations, by the diverse heights and contours of the bloom-spikes, and by the bold and varied outlines of the finely-formed leafage. *Yucca filamentosa* shows its densely-flowered spikes of ivory bells in the foreground, backed by the taller bloom-spikes of the handsome *Yucca pendula*, whilst amongst the *Yuccas* are interspersed the flower-rods of *Acanthus spinosus*, thickly set with pink and white blossoms. However attractive such plants may appear when in proximity to the dwelling-house, it is, perhaps, in the wild garden or in open spaces bordering

shrubberies that they are to be seen to the best advantage. In such sites delightful pictures are formed by colonies of *Yuccas* when in flower, and even when they are out of bloom their noble foliage renders them objects of interest. The dwarf-growing *Y. filamentosa*, *Y. flaccida*, *Y. pendula*, with gracefully bending leaves, and the tall *Y. gloriosa*, the giant of the family, sometimes attaining a height of 10 feet, with its erect, sword-shaped leaves and lofty, thickly-flowered spikes. Here, too, the *Acanthuses* are more at home than in the flower border, the strong-growing *A. mollis* throwing up its bloom-spikes to a height of 7 feet and more above its wide, deeply-cut leaves—those leaves whose graceful curve first suggested the capital of the Corinthian pillar. *Kniphofias*, with their glowing flower-heads, are also highly decorative when planted with discretion among natural surroundings, while in the south-west *Dracena australis* often perfects its odorous flower-spikes before attaining a stature of 6 feet. Few flowers are more attractive when growing naturally in the wild garden than white Foxgloves, the tall flower-studded wands waving with every breath of air or trembling at each impetuous incursion of the burly humble-bees into the drooping

chalices, while in many a cottage garden the Hollyhocks, double and single, with massive flower-spikes, crimson and pink, tower against the whitewashed walls, the embodiment of robust comeliness, and offer a prospect that causes many a passing footstep to linger by the lattice gate. Foxgloves are, naturally, but biennials and die after flowering, but are easily raised from seed, as are the Hollyhocks, though the latter are often treated by the cottagers as perennials and throw up spikes from the old stool year after year; but neither of these, beautiful as they are, can be compared for permanent effect with the subjects of this note, the *Yuccas* and *Acanthuses* enlarging their dimensions with the circling years and becoming more floriferous and decorative with each succeeding season. S. W. F.

Slag manure.—Could you or any of your readers kindly give me any information regarding the quality of patent slag manure, and if they have any experience as to its value as a garden fertiliser?—R. K. PATERSON.

* * * A soil which has for some considerable time been devoted to garden purposes differs considerably from agricultural land. It always contains a considerable amount of organic matter (humus), and the presence of this is eminently favourable to the direct assimilation of finely-ground phosphates; indeed, the results from the use of

phosphatic manures on garden soils are 50 to 60 per cent. better than those obtained from the use of the same manures on ordinary land. Basic slag is the cheapest source of phosphoric acid, and in this instance it would be the best kind to use. One of the chief objections to the soil of old gardens is that it contains too much organic and too little mineral matter. When, therefore, decomposed vegetable matter is added to such soil you are adding a substance of which there is already too much in the land, but when mineral manures are added the balance of organic and inorganic matter is better adjusted and more satisfactory results follow. Basic slag contains a large quantity—nearly 50 per cent.—of lime, the effect of which is to decompose the nitrogenous matter accumulated in the soil, liberating nitrogen for

the use of plants. In purchasing slag manure be careful to see that it is very finely ground, and also do not forget to use some potash manure—kainit for choice—in addition.—C. G. FREER-THONGER.

FRUIT AND VEGETABLE CROPS.

EASTERN.

Coldham Hall, Bury St. Edmunds.—The abundant crop of blossom on almost every description of fruit tree here this season has not been followed by an extra fine fruit season. Doubtless the dry winter and the long cold spring had a good deal to do with the deficiency. Apples are not plentiful in this garden, but, taking an average of many gardens of different kinds visited in the neighbourhood, I think there is an average crop. The need of planting good reliable late-keeping cooking varieties appears to be more than ever, and there is an unflinching demand for this class of fruit far exceeding the supply. With regard to varieties, a few of the most sure fruiting kinds generally are an absolute failure here King of Pippins and Dumelow's Seedling, two that have never disappointed as far as quantity of fruit is concerned, are absolutely bare, while Peasgood's Nonsuch, not always a sure bearer here, has had to be thinned considerably. Blenheim Orange is a fair crop. Ribston and Cox's Orange both poor. Lord Sulfield and the Codlin family generally are much behind their usual form. I do not grow the Juneating, but close at hand trees are heavily laden with small and not particularly well coloured fruit. Beauty of Bath is well cropped on small, free-trained trees, but espaliers of most varieties are almost bare, except where an extension shoot has been taken. Pears are very short, the best here being Beurré Diel Louise Bonne of Jersey, Williams' Bon Chrétien, Beurré Bosc, and Gansel's Bergamot. These are all bearing a medium crop of nice clean fruit, but nearly every other kind grown is a total failure. Plums are scarce, my best being The Czar, one of the most useful Plums ever sent out, Gisborne's, and the Early Transparent Gage. Cherries are not largely grown, but Elton, May Duke, and one or two others have borne very fair crops of medium-sized fruit. The difference between trees of both Plums and Cherries grown in firm soil and others where it is more lightly cultivated around them was never so apparent as this season. Under the former circumstances fruit is plentiful; with the latter there is more wood than fruit. Peaches outside were badly checked by the cold, ungenial weather, but are now looking much better, and there is a very fair crop on most kinds. Alexander and Bellegarde Peaches are the best. Inside the fruit has been remarkable for quality and colour. That splendid Nectarine Early Rivers improves annually, but the fruit in an unbeated house of this and Hale's Early Peach are about ten days later than last year. Walnuts and Filberts are a medium crop only. Of small fruits, Strawberries have been a remarkable crop, the first year plants especially. The fruit has been large and of excellent quality throughout, that fine, though erratic, variety Monarch having much improved here this season. Latest of All is still (August 4) giving an occasional dish, thus for once, in this garden at any rate, being true to its appellation. Dr. Hogg has been very fine, but the Gunton kinds are again a miserable failure. Gooseberries have borne excellent crops of fine fruit; Raspberries and Currants good. Damsons are a failure.

Vegetables have been later than usual, but good in all cases. Potatoes are lifting well, and although disease is rampant in the neighbourhood I have not as yet had a bad tuber. Sharpe's Victor I still grow, as it is certainly earlier than the better flavoured Myatt's. I never had the soil in better working condition than this season, consequently germination has been rapid and sure. Root crops are all good and clean with the single exception of Turnips. Broad Beans were excellent; Kidney Beans later than

usual, but now bearing very heavily. The whole of the Onion crop was sown under glass and transplanted, and the result justifies the trouble taken. Autumn sown Onions run away to seed rather badly, but few were wasted owing to a short crop. Salads have been abundant and good owing to the cool, moist weather during the greater part of the summer, and all classes of winter greens are looking well.—H. R. RICHARDS.

Anstey Hall, Trumpington, Cambridge.—Strawberries have been very abundant, Royal Sovereign being the best. Gooseberries, Black, Red and White Currants are very plentiful. Raspberries fairly so. Peaches were nearly killed with the blister and curl in the leaves, and in consequence most of the crop has fallen and the fruits that are left will be small. Apricots are dropping even at this date and will be a thin crop. Plums are a complete failure and very much blighted. Apples are nearly as bad; in some orchards there are none, as in all, the leaves look as if they had been syringed with hot water, the fruit and leaves dropping as if it were October. Pears are scarce. In early spring I never saw a better promise for fruit of all kinds.

All kinds of vegetables are looking remarkably well, although somewhat late. Onions are in some neighbouring gardens mildewed. I took the precaution to well dust mine in the evening with ground lime, which I believe has kept them clear. Cauliflowers are and have been very plentiful. Brussels Sprouts, late Cauliflowers and Broccoli are promising. I never saw vegetables in more abundance. French and Runner Beans and Vegetable Marrows are late, but look very promising. Potatoes are above an average crop, but the disease has shown itself in several places here.—C. FORBES.

Ashwellthorpe Hall, Norfolk.—As far as this garden and neighbourhood are concerned, the fruit crop on the whole must be described as below the average. Apples are certainly better than last year, but the fruit is undersized and the trees much blighted. Pears are a very poor crop; Plums rather better; Cherries very scarce. Peaches and Apricots are a fair average crop. Strawberries are abundant, especially Royal Sovereign. Outdoor Figs are a good crop. Raspberries above the average; the dry weather rather interfered with the late gatherings. Walnuts are very scarce; other nuts abundant. Black Currants and Gooseberries are very heavy crops. The favourite Gooseberries in this neighbourhood where they are very largely grown for market are Keepsake, Whinham's Industry, Crown Bob, Lancashire Lad and the Old Warrington.

All vegetable crops have been good. Peas I have never known to do so well. Both early and late sorts have been abundant. Onions are doing well, and the Celery up till now is free from the maggot. Potatoes both early and late are excellent, but I am sorry to find the disease very prevalent. Tomatoes outdoors are quite a failure this season.—T. B. FIELD.

WESTERN.

Tortworth, Falfield, Gloucestershire.—The fruit crops in this district this season are on the whole under average. Apples and Pears, also Plums, have prematurely fallen from the trees. Insect pests have been and still are very troublesome. Peaches and Nectarines are an average crop and very good; small fruit over average and good.

The vegetable crops generally are very good. The Potato crops are now somewhat prematurely ripening, possibly from lack of moisture. The tubers are smaller than usual, but very good and quite free from disease as yet.—T. SHINGLES.

Killerton, Exeter.—Apples generally are below an average crop. Among the best bearers this year King of the Pippins stands first, while Blenheim, Tower of Glamis, Mère de Ménage, Cornish Aromatic, Lady Henniker, Stirling Castle, Cellini, Schoolmaster, Worcester Pearmain, Tom Putt, and Reinette Blanche d'Espagne are very good. Pears are also below

the average. Plums on walls are very scarce, but Early Prolific and Prince Englebert on standards in the orchard have good crops. Cherries are scarce, the trees being affected by the very dry weather. Peaches and Nectarines are also very scarce. Apricots are also scarce, the Shipley Apricot being the best this season. Small fruits have been abundant and very fine. Filberts and Cob Nuts are very plentiful, but Walnuts are very scarce.

Vegetables generally have been much affected by the dry weather. The early and second early Peas had good crops, but later sorts were much affected by mildew. Scarlet Runners have been later than usual, but are now bearing well. Carrots, Beets, and Parsnips are good, but Onions have suffered from the drought. Good Cauliflowers have been scarce, Globe Artichokes most abundant, and Marrows very plentiful. Early Potatoes have ripened off; the crop is light, but of good quality. Schoolmaster is quite green and very promising, and being free from disease there is every likelihood of a good crop.—JOHN GARLAND.

Thornhill, Stalbridge.—Apples, Pears, Plums and Cherries are good; Peaches excellent; Apricots average; small fruits good and Strawberries under.

Generally speaking, the vegetable crops are of fair average quality, excepting Turnips, which the drought has seriously affected, and of Potatoes the early varieties are rather undersized, but excellent in quality, and with rain now the late crops give promise of an average supply.—FRANK SINGLETON.

Frampton Court, Dorchester.—The fruit and vegetable crops in this garden and neighbourhood have been fairly good this year. During the spring and early summer they were very backward, owing to so much dull weather. During July I gathered an enormous crop of Strawberries, also a very heavy crop of Black Currants. Gooseberries, Raspberries, Red and White Currants were about an average crop. Apples and Pears generally in the neighbourhood are much under the average, while Plums and Cherries are rather above average. Peaches look well at present and promise to be better than usual.

As regards vegetables, there has been no crop this year so good as Peas. I had an exceptionally good lot, but they came on with too much of a rush, all coming in at about the same time. Peas of the same variety sown a month later were fit to gather almost at the same time. Early Potatoes are very small, but the later ones generally are looking well, and I have not seen any signs of the disease anywhere yet. Vegetables are looking well, especially Carrots, Parsnips and Beet.—H. J. HARVEY.

Westonbirt, Tetbury, Gloucester.—A fine show of blossom in the spring gave every appearance of its being a good fruit year, but the spring frosts destroyed the Plum blossom, and the blight seriously affected the Apple and other trees, that on the whole the crop in this district is slightly under average. Most of the cooking Apples are bearing an average crop, but the fruits are very much deformed. Warner's King, Manks Codlin, and Annie Elizabeth are the best. Bramley's Seedling is not bearing well this season, but is an excellent variety to grow. The dessert kinds are poor, the trees looking wretched, the young growths curled and blackened with the blight. American blight, too, has been very prevalent this year. Pears are under average. Apricots are above average. Peaches and Nectarines good. The trees were very much blistered in the spring, but have grown out of this. Hale's Early Peach ripened on a south wall in July, but its falling is splitting the stone. Sea Eagle does well here on a south wall. Early Rivers is an excellent Nectarine both for outside and inside, but must not be allowed to grow too grossly. Cherries are average. Strawberries are good. Royal Sovereign is the principal one grown, but succeeds best when left only two years on the same ground. President and Sir Joseph Paxton both do well. Laxton's Latest of All is a very fine variety, and

when better known will be largely grown. Bush fruits are good. Whinham's Industry Gooseberry is an excellent sort both for picking green and excellent for dessert, improving as the bush gets older. Of Raspberries, Superlative is a good all-round variety, Semper Fidelis being best for the kitchen and preserving. Yellow Antwerp is the best of the pale yellow varieties. Currants, Red Dutch and Cherry, are both fine. Carter's Black Champion and Lee's Prolific Black are both good and vigorous in growth. The latter hangs the best. Walnuts are an average crop: Filberts and Cobs under.—A. CHAPMAN.

Bosahan, St. Martin—Apples are a fair average crop. Plums are rather below the average. Peaches and Nectarines (out of doors) are poor. Small fruit of all sorts, with the exception of Red Currants, is quite up to the average.

Vegetables of all sorts are unusually fine.—T. CRAWFORD.

NOTES OF THE WEEK.

Gladiolus White Lady.—Flowers of a very beautiful white variety of *Gladiolus Gaudavensis* come to us from Mr. T. S. Ware, Hale Farm Nurseries, Tottenham. The flowers are very pure and pretty in form, too.

Cestrum aurantiacum.—A useful and distinct as well as beautiful climber, with numerous terminal heads of nearly tubular flowers. Among climbing plants the shade of colour is not frequent, and being comparatively hardy is worthy of more attention than it receives as a rule.

Rudbeckia bicolor superba.—This handsome annual was exhibited recently at the Drill Hall by Messrs. J. Veitch and Sons. The flowers are very showy, and improve upon closer acquaintance. The colour is a bright orange-yellow with a deep crimson zone. In height the plant is from 2 feet to 3 feet.—D. B. C.

Tufted Pansy White Empress.—Autumn-planted roots of this variety commenced to flower as early as April last, and have bloomed ever since. At this time they are covered with numberless rayless flowers of a pale creamy white colour, and these are still of large size. The habit of the plant is fairly compact and dwarf.—C. A. H.

Phlox Aurora.—This handsome late-flowering Phlox deserves extended culture, as its bright and effective colour is a pleasing feature in the hardy flower border. It produces a large branching spike of showy flowers, which may be described as brilliant orange-scarlet with a rich crimson eye. It stands out as a thoroughly good and reliable sort to perpetuate.—D. B. C.

Sagittaria heterophylla.—This is a good and showy species from North America and one well suited for moisture-laden spots in the garden or in shallow water, where it is usually more vigorous because of the safety of the roots in the rich mud that congregates in such places. The flowers are about 1½ inches across, and produced in a loose pyramid, while the satiny texture of the blossoms is a rather pleasing character.

Thunbergia grandiflora alba.—A beautiful and showy subject, if, indeed, the purest of white flowers may be termed showy. As an indispensable subject among stove plants this handsome plant has but few equals, the flowers large and produced with considerable profusion where good plants exist. Where there is roof-room this handsome Indian climber should always find favour, if only for the exceeding purity of its flowers.—E. J.

Campanula Hoeti alba.—Though somewhat difficult to secure true to name, this handsome Bell-flower is one of the best of that set more nearly related to *C. linifolia* and others; indeed, a white form of this is too frequently substituted for the above, which is larger in foliage, as it is in blossom, the latter also more bold and the corolla more reflexed. It is also darker and denser in habit, and in other ways quite distinct when both are grown quite near for comparison.—E. J.

Aletromeria inodora.—At a short distance one may be pardoned for mistaking this showy plant for *A. psittacina* or a well-marked form of it, more particularly on account of the prevailing colour which exists, viz., a dark crimson with green. The above, however, is nearly 3 feet high, and comes from Brazil, so that it is possible that to some extent it may be

less hardy than others of its race. In a sheltered position alongside the Kew Palm house is a good group in full flower now.

Lathyrus grandiflorus albus.—This fine plant came before the floral committee of the Royal Horticultural Society at their last meeting, and is a vastly improved form of the old Everlasting Pea. When this new sort gets into general cultivation its fine qualities will be highly appreciated, both in the hardy flower garden for covering trellis-work and similar uses, as well as for cutting for decorations. The flower-spikes, as well as the individual flowers, are very large.—D. B. C.

Acæna microphylla.—Few alpine plants are of more interest than this when carpeting a given space in the rock garden and studded with its globular rosettes of crimson spines. When at its best the plant is more than interesting: it is really attractive, and for the combined reasons is worthy of good culture at all times. With plenty of soil for rooting into, a rather sunny piece of rockwork suits it best, but these are conditions which surrounding circumstances may require to be modified.

Anemone Halleri.—A few seedlings of this handsome species have been giving their first flowers of late from young plants that were bedded out in the early summer of last year. When fully grown the group promises to be a most attractive one, the deeply-cut and much divided leaves spreading out freely, and the handsome, erect cups, covered externally by a silken down, are of a rich dark purple within. This shade may, however, vary among the seedlings, as it does again in certain stages of the open flowers.

Seedlings from Tufted Pansy Pembroke.—This has been much admired all through the summer season, its large circular, rayless, clear yellow blossoms being quite distinct from all others, and they are much paler on the upper petals. Unfortunately, by July the growth becomes too leggy, and shows the need of an improved habit. From 200 to 300 seedlings of this variety raised in the spring there is now a most interesting result, and several plants with blossoms of a rich colour and possessing a more compact habit are flowering profusely.—D. B. C.

Rudbeckia Maxima.—This stately plant is noteworthy now in Waterlow Park. The flowers are large with long, broad, and semi-drooping rich yellow florets and a well-defined conical disc of a purplish maroon colour. The silvery green foliage of the plant is also striking. The height of the plant is about 3½ feet.—D. B.

Rudbeckia Newmani.—This is one of the most useful of the Cone-flowers, and just now is at its best. Isolated clumps in the hardy border are effective and always a welcome feature at this season, but to be fully appreciated it should be seen in large breadths, where, if used in conjunction with other hardy plants, such as *Pentstemons* and other equally showy subjects, the contrast is striking. This is undoubtedly one of the most valuable perennials in flower at this season.—C. A. H.

Dianthus cypelos.—Is it possible that the really fine form of this handsome single Pink is overlooked by gardeners as a rule? Not only is it good in form, but it is dwarf, freely flowered, and of good size. Individual blossoms of this fine single Pink are about 2 inches across, the petals remarkable for their smooth edge, and the pink shade rendered very attractive by a large crimson centre. A large bed of this has been very striking for some time past, and even now promises a still further display.—E. J.

Salpiglossis sinnata vars.—At the present time this beautiful annual is displaying its varying and well-nigh endless charming shades to advantage, and few things are more beautiful or interesting than a bed of these of a good strain. The flowers in their wonderful colours embrace shades that are quite unique, and doubtless a few years hence will see a marked improvement in the habit of these things, which is now frail and somewhat thin also. By a little care in raising the seedlings, the present straggling habit may, however, be modified.—E. J.

Cactus Dahlia Mrs. A. Peart.—To see this type of the Dahlia in proper form, with its neatly quilled florets, it must be grown thoroughly well. Under such treatment individual flowers

are very pretty, yet much of the beauty of the flower from a garden point of view is lost, because of the weak foot-stalks which characterise the growth. Instead of the flowers looking one in the face as it were, they overhang in such a way that they can only be seen satisfactorily by raising them with the hands. The colour is creamy white.—B. C.

Tufted Pansy Lavinia.—Although a more circular flower than *Violetta*, the original of the miniature-flowered Tufted Pansies, there is much beauty in this charming kind. It is a little later than the ordinary large-flowered varieties in coming into flower, but when once they begin to make their appearance they continue until the end of the season. At this time its pretty little pale bluish lavender blossoms, with a rayless yellow eye, are freely produced. This is one of the gems of the season, and was figured in *THE GARDEN*, February 19, 1898.—C.

Seedling Tufted Pansies.—Mr. D. B. Crane, of Highgate, sends us a charming series of his Pansy seedlings. Mr. Crane is working in an interesting way trying to get the flowers smaller even than *Violetta*, and we hope he will go on with this strain. It may be very precious for rock gardens, getting some of the small kinds of good colour. Being of a perennial nature these little Pansies will be among the best things to grow on rock gardens or walls. Their beauty of colour and distinctness fit them well for this purpose, and they will prolong the length of rock-garden bloom.

Placea ornata.—Mr. Perry, Winchmore Hill, sends us some flowers of this with the following note:—This was received from Chili with *Tecophylæa cyanocrocus*, and I believe it requires somewhat similar treatment. The last-named plant Mr. Burroughes, of Stamford, has had growing outside for many years, but not the *Placea*. I should think it requires a warm greenhouse to do it well. The flowers sent you were cut from small collected plants. I have had flowers here quite double the size, and four on a stem. I have had all mine grown in a cool greenhouse just kept from frost.—AMOS PERRY.

Gentiana asclepiadea alba.—Considerable use is made of this plant at Kew in the rock garden in a variety of places, and with good results generally. In some instances the blue and white combine, in others the species is represented by large clumps of several years' growth, and yet again a few are in raised positions, and the willow branches allowed their own way produce a very pretty result by mingling with other things with which they come in contact. In these raised positions where sufficient depth of soil is at hand this is one of the most beautiful and graceful of summer-flowering plants, and which in truth has no rival in its own genus.—E. J.

Acalypha hispida (Sanderø).—This plant novelty has been so abundantly referred to of late that little remains to be said concerning it. At the same time we call attention again to the plant because of some examples fully 6 feet high we have seen that were grown without stopping, and which appears to be much the best way of treating it. Thus grown, the plants retain the handsome leaves to the pot, while the reddish-crimson tail-like appendages depend over each other in a remarkably profuse manner, even to the very summit. The way the colour is retained in these drooping inflorescences is also noteworthy, and therein is much of its decorative value invested.

Veronica parviflora.—The shrubby Veronicas are all welcome in their season, and the one under notice I do not remember having seen so pretty in my garden before. The winter of 1894-5 killed the two old plants I had, but some young self-sown seedlings escaped, and these with others raised since are now very pleasing. Seedlings come up frequently here, and have now and then to be pulled up when they appear in quarters reserved for small growing alpines. The flowers are white and very profusely produced in spikes. I grew this Veronica for several years

without knowing its name until I saw it at Edge Hall.—S. ARNOTT, *Carsethorn, by Dumfriesshire*.

Rudbeckia laciniata Golden Glow.—My first impression of this double Cone-flower was not a favourable one, derived as it was from a cut flower which looked lumpy and heavy. Last year a good plant or two in bloom led me to think more highly of it, and longer acquaintance confirms the more favourable opinion. It is, I think, a plant which will give more pleasure if grown in a poor soil than in a heavy and rich one. In the former its naturally tall habit is checked and the flowers reduced in size. If grown in a sheltered place and left unstaked its natural grace is not destroyed, and it will be seen that its habit is in its favour, especially if it rises through dwarfer flowers.—S. ARNOTT.

Zauschneria californica.—Just now this is one of the most brilliant of the subjects flowering in the rock garden, the flowers, long and tubular in outline, being of a vermilion-scarlet shade. In certain districts this plant is not considered strictly hardy, but I do not think the experience general. One item should be kept in view when planting this. It is this—its liability to spread by stoloniferous growths, which require some space superficially. By means of these underground shoots, the plants if planted rather more deeply than usual may generally be depended upon to spring again even after hard frost, or, if the latter sets in, the plant by its strictly herbaceous character is one of those subjects easily mulched over for the time being.

The Cornish Heath (Erica vagans).—In the rock garden in autumn the Heaths are usually very attractive, and none more so than the Cornish Heath—*Erica vagans*. At present a large plant of the white variety, crowning a knoll on the rockwork here, is very pleasing. It is true that the red anthers protruding from the flowers take from its whiteness, but even this defect cannot prevent one from admiring the beauty of the plant. As an edging to a walk, where it succeeds the Cornish Heath is very pleasing. At Sharncliffe, New Abbey, N.B., there is such an edging, and, as it is kept in good condition, it always looks well. Where limestone is absent, *E. vagans* appears to succeed.—S. ARNOTT, *Carsethorn, by Dumfriesshire*.

Kniphofia Nelsoni.—Where only one species or variety of the Torch Lily can be grown, I should be inclined to favour this beautiful kind, simply because of its great freedom of flowering. Indeed, it is, I believe, one of, if not the most profuse of its now numerous race, while the dainty spikes, which are so exceptionally brilliant in colour, are large enough for all purposes of cut flowers and the like. Moreover, the stems are not of the great thickness of many kinds, an item alone that prevents the use of many in this way even in bold arrangements where a few spikes may not be out of place. In short, *K. Nelsoni*, whether in a cut state or in the border, is unique, not only for its useful size, but equally so for its brilliant colour, that in the long tubular flowers is seen to advantage.—E. J.

Lilium Henryi.—This lovely species is now well in flower at Kew, the plants sending up their stems several feet in height, so that the richly-coloured flowers may be easily seen. The group in question is planted in the middle of a bed of *Osmanthus*, compact bushes of about 3 feet high and as much through, the tallest stems of the Lilies being from 4 feet to 5 feet above the bushes. The colour in this Lily, a sort of apricot-orange tone, is very distinct, altogether removed from the more delicately-toned *L. Batemanni* in this respect, because of the orange shade overlying as it were the apricot hue. This remarkable Lily is usually described as orange-yellow, though I confess the latter colour very difficult to discover. That it is a splendid addition to hardy Lilies there is no doubt, and happily it appears more amenable to open-air culture than some, which is a great gain.

Incarvillea Delavayi.—It may be because *Incarvillea Olga* proved disappointing as a hardy

plant that *I. Delavayi* finds its way but slowly into our British gardens. Whatever the reason for its being so little grown, the sooner it becomes more widely known the better. It seems quite hardy, is by no means difficult to grow, and can be raised easily from seed. From seed it has been flowered the first season, but unless sown early and given good treatment it will not flower until the second year. It forms thick, fleshy tubers from which the attractive leaves and the spikes of long, Gloxinia-like, scarlet flowers are produced. It is quite hardy with us in the south-west of Scotland, and I saw it in Ireland last June in flower. It is superior in size and character of flower to *I. Olga*, and its greater hardiness is only an additional recommendation.—S. ARNOTT.

Aristolochia hians.—While not figuring among the largest of this very remarkable genus, the species here named is very striking in general appearance, as also in its markings. The flowers, which emit a very strong if not altogether agreeable odour, are produced somewhat profusely, and externally are of a greenish-bronze, with dark veins distributed over the somewhat inflated lower half of the flower. Internally, or rather the approaches to the tube and what may be seen by the casual observer, it is freely covered with hairs, while a blackish-maroon surface appears to surround the entrance to the tube. The above species, as also the much smaller though very beautiful *A. elegans*, are both flowering freely in the stove aquatic house at Kew, where they appear to delight in the warmth and moisture-laden heat that surround them.

Rosa rubrifolia or ferruginea.—This is a most distinct species, and worthy of more extensive cultivation. Just now young budded plants are of beautiful colour, the bluish wood, covered with bloom like a Grape, is quite thornless, and is no less attractive than the reddish leaves. These latter are also glaucous like the wood, and are seven in number. The dull red rather small fruits are not so bright as the fruit of some other Roses, but they have a showy appearance when quite ripe. This shrub seems to me as useful for decoration as the purple-leaved *Berberis*, and I am surprised it is not planted in large masses, for it retains the rich colour all through the summer and autumn. As with many other coloured shrubs good cultivation and hard pruning are required to keep them in condition. If allowed to become starved and to grow uncared for, they quickly become insignificant objects.—P.

Combretum purpureum.—In a collection of stove and greenhouse cut flowers we recently saw in the west of England appeared a fan-shaped spray or two of this fine old evergreen twiner. What is known as *C. purpureum* is doubtless *C. grandiflorum*, and it appears to do well in a warm conservatory or heated Fern house. Yet, as the late Mr. Thomas Buines says, "it must not be subjected to draughts in a cool house, as it is essentially a warm stove plant, coming from the hot, moist regions of Madagascar, and therefore cannot bear for any length of time either a low temperature or a dry atmosphere." The flowers are individually small, but they are freely produced in dense spikes, a number of which in the case of a well grown plant form a spray a foot in length and nearly as much in breadth. One can quite understand the beauty of this plant when it is seen in its native habitat adorning the forest trees of the tropics with immense festoons and garlands of their gay flowers. The most suitable soil for this plant is a good fibrous peat, with enough of sand added to keep it well open. The *Combretum*, being a slow-rooting plant, needs to be sparingly watered.—R. D.

Chironia baccifera.—In a very fine collection of plants staged at the Sandy flower show by Messrs. W. Cutbush and Son, of Highgate, could be seen a small specimen of the charming pink-flowered *Chironia baccifera*, the berry-bearing *Chironia* from Southern Africa. When in flower

one is reminded of a pink *Linum*, and the flowers are freely produced. Twenty years ago I used to see this species thrive in collections of stove and greenhouse plants in the west of England, but it is no longer seen. Someone used to grow it into capital three-quarter specimens, and it was always a prominent feature in the foreground of a collection, but the grower has probably passed away, leaving no successor capable of managing this plant. It is a soft-wooded greenhouse perennial, thriving in a fairly coarse mixture made of three parts of peat and one of loam, with plenty of coarse sand added. Abundant drainage is necessary and the plants should not be overpotted. Care is necessary not to over-water, and especially during the winter months. It is perhaps difficult to keep a specimen in the best condition until it becomes large in size, and this may account for the absence of the genus in present-day collections of stove and greenhouse plants.—R. D.

Some attractive Roses for their fruit.—The showiest seed-pods of all the Rose tribe are those of *Rosa pomifera*. The individual fruits are not quite so large as those of the rugosas, but better displayed upon the bush. The two-year-old branches cut back to about 3 feet from the ground produce laterals right up the shoot, which blossom and yield two to four fruits in a bunch. The glaucous foliage not being so dense as in the rugosas, allows these fruits to be all the better seen. They are about 1½ inches long, exclusive of calyx, and 1¼ inches broad. The colour is beautiful, the under side being orange-scarlet, and the upper a mulberry-crimson. They are not unlike large Gooseberries, having, like this fruit, numerous short hairs. The rugosas are well known and are undoubtedly highly useful shrubs in many ways. Apart from their beautiful flowers and fine leathery foliage, the fruits in the early autumn become most conspicuous. The single white variety has the best coloured pods. They are of a flat cheese shape and a bright orange-scarlet colour. The single rose-coloured kind has deeper coloured fruit, almost a mahogany shade, with scarlet underneath. Another beautiful Rose fruit is that of *Rosa alpina*. These are unusually long and narrow, and resemble some of the Capsicums. They are a bright scarlet, and, coming as they do on the smooth lilac-coloured wood, they are of very attractive appearance. The leaves are glaucous and nine in number.—PHILOMEL.

Crinum Powelli.—Where warm and sheltered positions exist in the garden this handsome subject is capable of fine results by reason of the exceptional characteristic boldness of its growth and the bold umbels of its flowers. All that is needed apart from the warm and sheltered position named is a specially prepared bed of deep soil with ample drainage. A knowledge of the bulbs and their size particularly will give cultivators a good idea of the depth necessary to accommodate such things, and at the same time provide a sufficient covering overhead. The latter, however, may be given from above in those circumstances where this is rendered necessary by the shallowness of the natural soil, or where a possible wet subsoil precluded the idea of descending to the requisite depth. Good loam and leaf soil in equal parts, and plenty of rotten manure worked in very deep, with some sharp grit, will do such things well, and it is necessary that the preparation should be good and genuine in every way, because of the time such things may remain when once well established in any given spot. Not less than 2 feet deep of good soil, and better still if 3 feet can be given, the whole being made tolerably firm below and also round about the bulbs. Above the bulbs this firmness should be moderated, otherwise crooked stems and the like may result. Usually this plant is grown in tubs in the greenhouse, and even here is a good subject with its bold stems towering away 4 feet or 5 feet high. At Kew, however, the plant is grown inside and outside, and of the latter examples may be seen right and left of the large Palm house now in flower, being represented by the above and likewise its white forms. In the

narrow border here the plants do well as a rule, but we remember seeing them in better condition than is the case this year.—E. J.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 30.

A MEETING of the fruit and vegetable committee was held on this date to examine Onions, Potatoes, Tomatoes, and Beets. The Onion breadth included many varieties both of those ordinarily grown in the winter and in summer. Long lines were sown of each variety in the autumn and again in the spring, whilst from the autumn sowing one other row was planted in the spring, each variety being thus represented by three rows. Some varieties, notably the Tripolis, usually regarded as the best for autumn sowing, withstood the winter fogs worst of all, and where plants did well their bulbs were in no case so good, handsome, or hard as were those of the brown or white Spanish forms usually sown in the spring. In not a few cases the bulb produce was very fine, but some few seemed superior both in excellence of stock, and in size and quality of bulb. Three were selected for three marks: Banbury Cross, a fine flattish round, style of Main-crop; Nuneham Park, a well-known fine white Spanish selection; Wroxton, fine globular form, first-rate both spring and autumn; and Rousham Park Hero, also very fine for both seasons. Sutton's A 1, a superb round Onion, especially good from the autumn sowing, and Cocoanut, a fine deep globular variety, both first-rate, had previously received awards. Very good also were Giant Zittau, Cranston's Excelsior, Eclipse, Trebons, and the Sutton's Globe. Potatoes were in great numbers. First earlies ran rather small, because of drought, but later ones were excellent, no less than thirteen new ones being selected for the cooking test. All were very fine croppers. Very little disease was seen, but a few varieties produced very coarse tops and few tubers, and some others, the great cropper Up to Date for instance, showing a good deal of growing out. Its dwarfier and earlier fellow from the same raiser, Challenge—tubers flattish round, handsome, and borne in great abundance—was entirely free from that defect, so also were many other strong growers. Eventually the committee, after tasting the admirably cooked samples of each variety, awarded three marks to Challenge; The Major, white, half long; The Queen, flattish round; Ellen Terry, great cropper, handsome white tubers; Devonian, kidney, white, superior flavour; Foo, kidney (from the Canary Islands), excellent; and Fishtoft Seedling, a wonderful cropper and fine for field culture. This is one of the best batches of new varieties seen at Chiswick for some time. Tomatoes showed comparatively little novelty. Three marks were awarded to St. Simon, fruits rich colour, medium size, very round and handsome; Stirling Castle, a great cropper, fruits medium size; and Peach Yellow, not a heavy cropper, but the fruits are of delicious flavour and of a pleasing sulphur-yellow colour, carrying a thick bloom. A variety named Semperfructifera, having small foliage and carrying huge clusters of small red Pear-shaped fruits, wonderfully pretty, obtained two marks as a decorative variety. The collection of Beets had suffered somewhat from the drought. The stocks were very good, but the best quality and colour were found in Cheltenham Greentop, which was recommended for a F.C.C. It was mentioned by Mr. Poupert that this was by far the most popular variety in the market, some growers having twenty acres of it. Three marks were awarded to a first-rate stock of Red Globe, the roots being very deep and dark in colour, with tops of more even form than are usually seen.

The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday,

September 6, in the Drill Hall, James Street, Westminster, from 1 p.m. to 5 p.m. A lecture on "The Disa" will be given by Mr. T. W. Birkinshaw at 3 o'clock.

ROYAL HORTICULTURAL SOCIETY'S SHOW, DUBLIN.

THE autumn show of the Royal Horticultural Society of Ireland was held in the grounds of Merrion Square. Though the weather was not fine, the attendance was very large. The entries exceeded those of last year, and the quality of both the fruit and flowers was very high. Among the particular features of the collection of cut blooms was the grand display of Begonias. The collection of forty-eight blooms, which obtained for Lord Ashbrook the challenge cup, value £10 (presented by Lady Ashdown), was a splendid exhibit. The variety of the blooms was no less remarkable than the fulness and richness of each flower. Messrs. Richard Hartland and Son, of the Lough Nurseries, Cork, were awarded a first-class certificate for three new specimens of Begonias, viz., Lady Ashbrook, a bright canary-yellow; Lord Ashbrook, salmon-pink, with white centre; and H. R. O'Kearney, cerise colour. Messrs. Alexander Dickson and Co., of Newtownards, showed a collection of Roses, and their stand of forty-eight blooms was awarded first prize. Their collection was also recommended by the judges for the certificate of the council. Messrs. McGredy and Son, of Portadown, were also among the successful exhibitors in Begonias, being awarded a silver medal and other prizes. Carnations were a particularly fine collection. Mr. Forbes, Hawick, took the silver medal for his collection. Messrs. Ramsay and Son, Ball's Bridge Nurseries, had on view a splendid collection of plants and cut blooms. The latter comprised Dahlias, Roses, Gladioli, Begonias, and Asters, and the whole constituted a beautiful exhibit. In plants, the group from the Botanic Gardens, Glasnevin, sent in by Mr. Moore, curator, commanded universal admiration. The rare and beautiful specimens constituted one unique feature of the show, and the fruit was particularly good. A great number of new exhibitors entered the lists this show, and the council of the society noted this fact with pleasure, as it indicates new interest in their work. Another interesting feature of the show was the appointment, for the first time, of a lady judge, Miss Curry, of Lismore, Waterford. The stands of Messrs. Hogg and Robertson and Sir James W. Mackey and Co., which were located on the grounds, and displayed a superb collection of bulbs and seeds, formed another feature of the show.

National Chrysanthemum Society.—On Monday evening last the executive committee of this society held a meeting at Carr's Restaurant, Strand, when Mr. T. W. Sanders presided. The minutes of the previous meeting having been read and confirmed and other routine business, such as correspondence, etc., dealt with, the secretary, Mr. Dean, gave a statement concerning the annual excursion, which was generally considered to be highly satisfactory. A vote of thanks was passed to Mr. Dean for the able manner in which all the details of the outing were carried out. The meeting next proceeded to the election of the arbitration committee, which is constituted as follows, viz., the officers, with Messrs. Moorman, Outram, and Fife, three to form a quorum. A vacancy on the executive committee that has arisen by the resignation of Mr. Daniels, who is leaving London, was filled up by the appointment of Mr. H. A. Needs. It was resolved that the details relating to the annual dinner should be left in the hands of a small sub-committee, and the following gentlemen were nominated for the purpose:—Mr. Simpson, Mr. A. Taylor, and Mr. George Gordon. The subject of a supplement to the official catalogue was raised, and the meeting decided that the work should be postponed until after the season's novelties had been seen. New members and several affiliated societies were elected.

PUBLIC GARDENS.

Prince George's Ground, Raynes Park.—The Grocers' Company have granted 100 guineas and the Leathersellers' Company 10 guineas towards the £10,000 which the London Playing Fields Committee are trying to raise for the purchase of Prince George's Ground, Raynes Park, as a playing field for Londoners of the poorer classes. The amount secured up to the present is about £6,300. The balance has to be found before Christmas, when the committee's option to purchase expires.

Roses for climbing through trees.—Will anyone kindly give names of Tea, Hybrid Tea, and Noisette Roses that can be counted on to climb through trees.—A.

* * We think you would find the following useful and free-growing Roses of the Tea, Hybrid Tea and Noisette tribes suitable for climbing through trees:—Aimée Vibert, Belle de Bordeaux, Cheshunt Hybrid, Climbing Captain Christy, Desprez à fleurs jaune, Gloire de Dijon, Kaiserin Friedrich, Longworth Rambler, Mme. Alfred Carrière, Mme. Berard, Mme. Marie Lavalley, Marie Robert, Pink Rover, Reine Marie Henriette, Reine Olga de Wurtemberg, Réve d'Or, Souvenir de Mme. J. Metral, Waltham Climber No. 1. We should advise you if practicable to insert at the base of the tree a fair-sized cask filled with good compost consisting of fibrous loam three parts, decayed cow manure one part, and small quantity of bone-meal. By planting the Roses into this compost they have a far better chance of succeeding, and the cask would prevent the roots of the trees from robbing those of the Roses.

The weather in West Herts.—The past week, taken as a whole, was of about average temperature. The temperature of the soil at 2 feet deep has, however, fallen 3°, and at 1 foot deep as much as 5° since the last report was issued, but is still at both depths between 3° and 4° warmer than is seasonable. Rain fell on three days during the week, but to the total depth of less than two-tenths of an inch. The ground remains very dry, no measurable quantity of rain-water having come through either percolation gauge for ten days. With the exception of 1893 the past month was the warmest August experienced here during the thirteen years over which my observations extend. The hottest period was from the 11th to the 23rd, when the highest day temperature never fell lower than 75°, and on six days exceeded 81°. Rain fell on twelve days to the aggregate depth of 1½ inches, or less than half the average amount for the month, making this the driest August for eleven years. It was a sunny month, the mean duration of bright sunshine being about three-quarters of an hour a day in excess of the August average. The summer of 1898 proved a warm one, but not so warm as any of the three previous summers. The rainfall was considerably less than half the average quantity for the quarter. Indeed, with the exception of 1887 this was the driest summer in this district during the past forty-three years.—E. M., *Berkhamsted*.

Carnation book (H. W. Williamson).—The "Carnation Manual," published by Cassell and Co., contains the best information about Carnations (not illustrated). It gives no information on Pinks. That must be obtained from the gardening papers.—J. DOUGLAS.

Rust in Begonias.—My Begonias, Gloxinias, and the earlier Cyclamen, have suffered from rust. The house is a three-quarter space. I have air in at the top and also open a little the front sashes. The houses were painted and properly cleaned, and I do not understand how it comes about. Some of the plants I bought this year I have had to throw away. I must give up growing or discover if possible some remedy.—W. G.

Name of plant.—M. Moody.—Medicago Echium.

ORCHARD AND FRUIT GARDEN.

NOTES ON APPLES.

THERE are some few varieties of these hardy fruits that seem to have generally borne better this season than have others, and it is possible that on such a fact may be presently based the assumption that these are the most reliable varieties to grow. It is very easy to leap to conclusions that are not correct, although there can be no doubt but that some few varieties, notably Manks and Hemskirk Codlins, are invariably very good croppers, but equally there can be no doubt but that the best cropping trees of Apples this year are those that did not fruit materially last year. On the other hand, I have seen myriads of trees that fruited freely last year almost fruitless this season. That is a fact which has to be taken well into consideration when dealing with the erratic results of one of the finest blooms on record, as it does seem evident that the comparative inability of the trees to produce fertile bloom had more to do with the lightness of the present crop than had the dull, cold spring. Naturally if the weather did so much injury to the bloom, how was it that some trees have such good crops whilst others have no fruit? The prevalence of certain weather so universally last spring does not fully explain that, especially when we see these diverse results in the same garden or orchard, whereas the assumption that it is a question of fertility of bloom does explain it. But just as one swallow does not make a summer, so do not one or even two rather sparse seasons indicate that hardy fruit growing is a failure. So far from that being the case, we see this season almost record bush and Strawberry crops, and in many places really excellent tree crops.

Fruit reports are naturally pessimistic. They are the outcome generally, and this season particularly, of the exceeding bloom promise and the poor fruit produce. Still, seeing that the majority of the reports were written some time

since, and both Apples and Pears have materially increased in size since, there is more reason to believe that there is a better crop of these fruits, and Plums also, than was looked for earlier. The special trouble with Apples during the past month of August has been, beyond great heat, almost unwonted dryness. No doubt the soil has been very dry, especially low down, where the tree-roots are, so far out of the reach of the showers that here and there have fallen. There is now not the least expectation that there will be any material rainfall sufficient to go deep ere the leaves have matured, and when the leaves fall there will be no danger to the buds should very heavy rains come, as the sap will be resting or congealed. Indeed, there could hardly be a better aid to the production of a very fine tree crop of fruit next year than would be a saturating wet winter, as, with the wood so hard and ripe, and the branches so thickly studded with fruit-buds, only this soaking for the roots is needed to enable these buds to produce fine fertile flowers next spring. If the needed heavy rainfall does not come, the prospect of getting a fine tree fruit crop next year will be far from rosy. Although what crop there is of Apples seems to be fairly distributed between dwarf and tall or standard trees, yet all sections of trees have been largely feeling the unusual dryness at the roots which has so long prevailed. If the dwarf trees give the finest fruits, they shed their fruits the most readily. Thus it may be assumed that, dry as are the subsoils, and deep, too, yet the trees which have their roots deep down in the ground are finding more moisture than those whose roots are near the surface. Of course, such dwarf trees could be readily benefited by giving them liberal soakings of water, but in how few cases can such supply of moisture be furnished, especially where all other crops and also lawns and shrubs are needing moisture even worse. During such a season as the present there could hardly be a boon more valued by the hardy fruit grower than a liberal supply of liquid sewage. That,

however, instead of using for the benefit of our tree and other crops, we prefer to pour into our rivers and the sea, thus wasting that of which we have such absolute need. It is one of the difficulties surrounding Apple culture on an intelligent basis that whilst trees thrive best, and find most moisture for the roots, in low-lying situations, especially in alluvial valleys, yet such positions are, of all others, the most dangerous to the bloom in the spring. How often have we seen the bloom on trees in valleys almost destroyed by spring frosts, whilst the bloom on trees planted on the higher ground, and especially on hillsides or airy slopes, where, of course, there is less root moisture, is probably quite unharmed. This fact shows the importance of choosing suitable and airy sites for Apples rather than those which, if on rich holding soils, are yet readily influenced for evil in the spring by humid atmospheres and mists. There is rather a craze for large-fruited varieties, doubtless because such fruits wear so noble an aspect on the exhibition table. But the best average fruited do not produce the largest fruits, as the two Codlins already referred to indicate. Then of ordinary kitchen and capital market varieties there are few better average croppers than are Duchess of Oldenburg, Stirling Castle, Cellini Pippin, Frogmore Prolific, Cox's Pomona, and Lane's Prince Albert. An extensive orchard planted with these varieties alone for market would be well furnished, and very probably, taking an average of years, the product from a given number of trees would be greater than from so many of any other eight varieties. None are coarse growers; they begin to fruit fairly early, and may be planted closer together than can other famous and favourite varieties that have not the same average cropping qualities. The practice of growing Apples as espaliers is not too common, but whilst these trees are few, I have noted that from year to year they seem to fruit with exceeding regularity. Such trees are easily cleansed and pruned; as easily protected from birds by net-

ting; and not being swayed by wind, fruits are readily thinned, and these invariably come fine and handsome. A. D.

Apple Kerry Pippin.—This old-fashioned but highly esteemed Apple will soon be fit for table, and those who prefer a crisp eating aromatic-flavoured fruit will find it hard to beat while in season. It is one of those sorts which produce good crops of fruit in most seasons, and can be relied on. The fruits are small it is true, but quite large enough for dessert. It is a hardy grower and succeeds equally well grown in any form of tree. A good-sized standard or a bush tree is capable of carrying a great weight of fruit, so that one or two trees at the most would be a sufficient number for providing fruit for private consumption.—A. W.

Strawberries in frames (F. W. M.).—In asking for information respecting the culture of Strawberries in cool frames, we assume that you refer to planted-out ones. For that purpose make up a bed on a warm border the exact dimensions of the inside of a wooden frame. Let the soil be good, and, of course, it will be several inches higher than the surrounding soil. Plant this 9 inches apart with strong-rooted runners, the very earliest laid into small pots, from some good variety. Some other soil or long manure may be banked against the sides of the bed or beds until January. Then this may be chopped away and the frames dropped over the beds. That will bring the Strawberry plants near to the glass when the lights are on. Give the plants plenty of air in open weather. They will bloom three weeks earlier and fruit before the outdoor beds.

Apple Scarlet Nonpareil.—My experience with this Apple may be uncommon, but I find it to be one of the shyest bearing varieties grown here, either as a garden bush or orchard tree. I do not remember having had anything approaching a good crop. This I much regret, as when in season it is one of the best dessert Apples. Loudon in his catalogue of Apples describes it as a good bearer, and this character has been given it by different writers, and more especially by those who live near to and south of London, so it probably succeeds best in warm localities and is not suited for universal culture. The tree here makes an abundance of lateral shoots and keeps very healthy, but does not increase much in stature. I am not at all sure of the stocks on which it is growing, and these may possibly be the cause of its shy bearing.—J. C. TALLACK.

Work amongst Strawberries.—Being tired of waiting for rain, I have had the whole of the Strawberry plants set out in their permanent quarters. The plants were thoroughly soaked previously to being knocked out of the pots and were again well flooded as soon as planted. So far they look quite fresh and have commenced to grow, but watering will have to be followed up to keep them growing. When opening out the holes to receive the roots of the plants the soil was found exceedingly dry, the previous crop having been early Potatoes, and it will take quite twenty-four hours' steady rain to moisten it any distance down. The dry weather, on the other hand, has been of great assistance in getting plantations cleared of the oldest foliage, runners and weed growths. The plantations, too, which were due for clearing off, having been on the ground three seasons, were also grubbed up. These after laying a day or two became so dry that, together with the rubbish from the other plots, they were able to be burnt on the spot. This saved the labour of wheeling the rubbish away and the ashes became serviceable for digging in when preparing the ground for a very early crop of spring Cabbages. The oldest of the remaining plantations will have a mulching of thoroughly decayed hotbed material spread between the rows as soon as time and labour will admit. This will be well worked up round the collars of the plants, as the crowns are raised too much above ground to allow them to run the

risk of passing through the winter without such protection. In addition to its shielding them from the harmful effects of very severe frost, it also benefits the stools to a marked degree, as fruits are pushed out into the material in early spring. These, it is almost needless to say, are of the greatest assistance to the plants when perfecting the crop.—A. W.

GOOD APRICOTS FROM SEED.

TO THE EDITOR OF THE GARDEN.

SIR,—I am enclosing with this some specimens of seedling Apricots. The four fruits wrapped in tissue paper are from one tree, and I think it is a very fine Apricot indeed, with a flavour equal to any I have ever tried. The tree is a first-rate grower and quite distinct from any of the named varieties, as also are the fruits. The single fruit (unwrapped) is a later variety and very good also. None of the fruits are quite ripe, but it was necessary to pick them to keep them from the insects, and I think they will ripen with a day or two of storing. Both were raised in Mr. Paley's garden at Ampton, and are from the original trees. I hope to be able to send you fruits of some seedling Peaches another year.—J. C. TALLACK, *Livermere Park Gardens.*

* * This is a very interesting communication. They were large and well-grown Apricots, above the average size, and excellent in flavour, although gathered slightly before their time. The Apricot tree shows more than any other the evils, to which we have frequently called attention in THE GARDEN, of the art of grafting. Except in a very few districts in England, there is scarcely a fruit garden in which the Apricots are in a healthy state; and this has been going on for generations, judging by the old essays in books which have attempted to account for the gumming and always evident disease in gardens. We think it is simply owing to grafting the plants on a wholly different one—the Plum. There is too much difference between them to allow of perfect health, and we think that if every person interested in Apricots were to sow the seeds of good kinds he would be able to settle the question for himself. He might raise inferior fruits, but he might get very good and even better ones than are now in cultivation by growing them in the cordon way until they fruited, when it would be easy to pick out and reject the bad. It would also be surely worth the while of some nurserymen to layer some of the very best kinds to see if we should in that way get over the great trouble of gumming.—ED.

Figs in pots (St. Petersburg).—We have read your letter carefully through, and find it exceedingly difficult to furnish you with a reply satisfactory to you. Really your practice seems to be so identical with the best prevailing here that it is almost impossible to find the weak spot in it. We can but infer that you may be troubled with some subtle fungus amongst your Figs in pots that attacks the fruits at a particular period in their swelling, causing them to prematurely fall. With us such trouble is seldom, perhaps never, heard of. There is no more successful illustration of Fig culture in pots than can be seen in the Royal Horticultural gardens at Chiswick, a few miles west of London, where in a large, roomy span house the plants in pots, ranging from 9 inches to 14 inches over, do wonderfully well. They include all the best-known varieties, are grown in a moderate heat, have the floor of the house kept fairly moist, and fruit abundantly over the several summer months. All round the sides the plants are on open shelves, and in the centre on a solid soil-bed, but all alike do well. The position is very unfavourable in the winter, as the locality is very subject to fogs, but of course then the plants are at rest. Can you try syringing yours, and the house also, with the Bordeaux mixture—copper sulphate and lime—after the leaves have fallen, and are gathered up and burnt? Of course, no such dressing could be applied when the plants are in fruit. The cli-

matic conditions surrounding your plants, of course, differ materially from ours. Fig trees in pots, not possessing that rapid power of recuperation found in the free-grown wall trees, recover from the cutting out of large, old wood badly, canker sometimes resulting. Perhaps coating the wound with Stockholm tar would enable it the sooner to heal over.

Vine borders.—When I recently saw the really superb crops of Grapes, the bunches so fine, so numerous, and the berries so large, carried by the Vines at Tewkesbury Lodge, Forest Hill, I was not at all surprised to learn that the primary constituent of the borders was a stiff clayey turf taken from the surface of the hill on which the vineries stand, and the base of which is a mass of solid harsh clay. It is very evident that many Vines failures come from lack of substance in the borders. The loam used is at the outset too light and porous. Then there is added to it too much light or gritty material, and usually far too much of soluble matter in the shape of manure. The border may be solid enough for a few years, then much of the matter in it is dissolved. It is then very porous, soon dries, the roots seek elsewhere for moisture and fail to find food, and bad colouring, shanking, mildew and other evils follow, all arising from the same cause—too great porosity of the border. These at Forest Hill have been made some nine years, not being at all changed, but simply from time to time added to. Because of the substance of the chief constituent in them, the Vines are in splendid health and are carrying superb crops. The gardener, Mr. Taylor, is a well-known exhibitor, and his products show that although for seven years past almost myriads of prizes have been won by the Grapes taken out from these comparative small vineries—for there is in all but a span range 75 feet by 25 feet—the bunches this year are as fine and as numerous as ever; indeed, the Vines and their crops represent a triumph in Grape culture. The very stiff soil of the borders is partially tempered by the mixing with it of some burnt clay and wood ashes with a little lime rubbish. Still, the virtues of the stiff soil are too well shown to be questioned.—A. D.

RIPENED WOOD.

THERE is no detail of greater importance in fruit culture than that of thoroughly consolidating the growth made during the summer. But many growers have a very indifferent notion as to what the term ripening means. It is not, perhaps, a good term, as it is so frequently used to denote when fruit is fit for use, and, as the ripening process is usually accelerated by sunshine and dry heat, we are apt to forget other aids to development. The more the wood of all fruit trees grown under glass is exposed to sun and air the better, but these are not the only factors, and I think I may say they are not the most important. It is too much the custom to look on a fruit house that has perfected its crop as a house that needs no attention beyond throwing it open wide to every wind that blows. Peach and Nectarine trees that have been carefully tended until the fruit is finished are left to do their best with often a lot of red spider and other insects upon them. Only recently an experienced (?) fruit grower told me he never syringed his trees after the fruit was gathered, as it "prevented the wood ripening." In his case the trees were healthy and clean, and of course syringing was not so much needed, especially as root moisture was not being neglected, but in numerous cases that have come under my notice trees are left with the borders absolutely cracking for want of moisture, and foliage flagging owing to the ripening process that was supposed to be going on. Now as a matter of fact healthy trees in autumn, after the crop has been gathered and the full amount of air put on, require even more water than when the fruit

was ripening. The borders are more exposed to drying influence, and if the foliage has been well preserved the evaporation from this is very considerable. All useless wood, *i.e.*, wood that has fruited and is not required for laying in, should be taken out immediately the crop is removed, which will allow the foliage on the remaining shoots to have the full advantage of sun and air, and by properly carrying out their function of sap-elaboration to strengthen the buds at their bases. Many varieties are prone to crack if very moist at the root when the fruit is finishing, and this makes it the more necessary to give a thorough soaking immediately the pruning is done. Wet every portion of the border, and on hot days well wash the foliage with the syringe at least twice. The parts of the trees nearest to the glass, or the apex of the roof in sunny corners, and over the hot-water pipes should come in for especial attention, applying the water forcibly and not using it too cold. Increase the air immediately the fruit is gathered, until in a few days the house may be thrown open entirely. It is the same with Vines and all tropical fruits; throwing a house open and allowing the roots to get dry, the foliage at the same time being crowded and covered with insects, is supposed in some mysterious way to act beneficially on the next season's crop, but a little thought on the part of those in charge must show that it is wrong. Much more depends upon the leaves being kept healthy until the last than is generally supposed. And they fall quicker when the proper time comes, for, of course, the loosening of the stem and fall of the leaf is just as much part of the work of the Vine or other tree as is the bursting of the buds in spring and the subsequent development of the fruit. And this is the point I wished most to emphasise in this note. It is the greatest mistake to substitute roasting for ripening. To develop the wood properly, and to make it capable of producing a good crop of fruit, all the natural forces of the plant must be kept going. Growth is one part of Nature's scheme, rest is another, and to try and force a Vine or other fruit tree to ripen its wood prematurely is just as wrong as undue haste in the earlier stages of forcing.

With regard to late lateral growth on Vines a good deal of misconception exists, and this, too, has its bearing upon the point at issue. Here, as in many other details, the middle course is the safest. I like to see a little late growth, and especially on young Vines. It keeps the sap moving and encourages the roots to activity. Very close stopping, or the entire removal of laterals, may possibly cause eyes to push that are better dormant, but to allow the growth to ramble away at will is wrong, leading often to shading of the principal leaves and doing more harm than good. Where there is room I let about four leaves form before pinching, but otherwise continue to stop at the first leaf when this is about the size of a crown piece. Respecting bud dropping on very early Peaches, which some growers attribute to too liberal treatment after the fruit is gathered, I think this can only happen after a check of some kind. I only grow Waterloo of the very early varieties, and speaking from my own experience of it can say that I never get the least trouble in this way, though it is in the same house with much later kinds, and if there was anything in the over-ripening theory I fancy this would suffer, as even the late kinds are treated as advised above. H. R.

Diseased Melon root (*An Old Subscriber*).—The roots are infested by eel-worm. This much-to-be-dreaded pest is more often destructive

among Cucumber plants than those of Melons, and in either case is difficult to contend with when once it is established in the roots. Little's soluble phenyl, a strong disinfectant that chemists supply to order, applied in good time is to a certain extent remedial, and can be strongly recommended as a preventive. Two ounces, or a wineglassful, to two gallons of water will most probably be found safe and effective. Light spongy soils and decaying vegetable substances or much manure favour an attack of eel-worm, and their use should be avoided. Besides, Melons succeed best in a strong loam to which fine mortar rubbish or a sprinkling of artificial manure has been added. The roots sent were not so knotted as might have been expected, and I should not be surprised to learn that the old-fashioned but faulty plan of drying off the plants at the roots when the fruit had reached the ripening period had been followed. In this case the usual early collapse of the plants would have been hastened by the eel-worm attack, but the latter need not be solely to blame for the failure. Next season strong loam that has been exposed to the action of frosts should be employed, frosts destroying any eel-worms there may be in the soil, and in addition a free use of hot lime, both for dressing the walls and any soil there may be under the staging, should be resorted to. Allowing the soil to become very dry underneath, through merely wetting the surface instead of giving a thorough soaking, has been responsible for bad eel-worm attacks in Cucumbers, and might also in the case of Melons.—W. I.

KENTISH FRUIT CROPS.

RASPBERRIES.

MANY excellent articles have from time to time appeared respecting the culture of this useful and delicious fruit, but Raspberry growing, as it concerns the majority of private gardeners, consists of looking after the welfare of a few rows of canes trained to permanent wires across the quarters of the kitchen garden. The crop under these conditions is more or less a permanent one, and methods of cultivation are generally well known. The end in view is to supply the requirements of the kitchen, reserving just the pick of the fruit for the dessert table, and, as the crop under favourable conditions of culture is a fairly certain and prolific one, it is not a source of much anxiety to the gardener. There is, however, another phase of Raspberry culture, namely, that which supplies the public, not only with ripe fruit in the season, but with jam all the year round, and the manufacture of various drinks for which the juice of the Raspberry is largely used.

In the days that are gone by, when every good housewife procured her own fruit and transformed it into home-made jam, wholesale fruit growing was not the business it is at the present day. Comparatively few people now-a-days indulge in home-made articles of food, and every season tons of Raspberries are bought up by preserve makers and converted into jam. Whatever may be said against the wholesale manufacture of commodities such as this, there is one sound argument in its favour. It has created a demand for immense quantities of fruit, and this demand is being largely supplied by cultivators of land who have found that, by altering their methods of procedure in accordance with the requirements of the times, they have fared better than if they had followed lines that paid well enough in their day, but have ceased to be profitable. Foreign competition is often set up as being the skeleton in the cupboard of English fruit growers, and so far as hard fruits are concerned the foreign grower is a serious rival. But with soft fruits and Raspberries are a case in point—there is little to fear in this respect, as the nature of the fruit pro-

hibits it being carried over the long sea journeys. The industry, then, is our own, and the large quantities of Raspberries used for different purposes are supplied to a great extent from British land by British labour.

But where does the fruit come from? You may travel over county after county and find in every garden Raspberry canes to supply the wants of the household, but not a single instance in which the fruit is grown on a large scale for sale. The presence of the fruit in private gardens everywhere is evidence that the Raspberry is not fastidious as regards soil and situation when grown under favourable, well-defined conditions, and yet it appears that it is only in certain favoured localities that Raspberries will lend themselves to field culture, for, like many other fruits, we find them confined to localities. Kent is the home of all British fruits, and, by taking Sevenoaks as a centre, a tract of country in the vicinity may be traversed which is responsible for the production of more Raspberries, probably, than any similar area in the United Kingdom. Strawberries also are at home, and a combination of the two forms the staple crop of many of the farmers. The rich, strong loam resting on the famous Kentish chalk is well suited for the requirements of the Raspberry, and out in the open fields may be seen canes of a character so strong, sturdy, and fruitful, that they would be the envy of many a gardener who has tried all the devices he knows to get such results, but without success.

The Raspberry season is now practically over. It follows closely on the Strawberries, and after the rush of the former fruit is past growers turn their attention to the latter. In some instances the earliest and finest of the fruit is picked and sold in small punnets for dessert purposes, but this trade is comparatively a small one. The Kentish grower likes to dispose of his fruit wholesale. Much of it goes direct to the jam-maker, who makes arrangements for the purchase of what he requires beforehand. Many tons also pass through the market, some in the neighbourhood of the metropolis being transferred from the fields by road, and large quantities are also sent to all parts by rail. The Raspberry grower has to be very much on the alert when the fruit is ripe. Unlike some other fruits, Raspberries cannot be gathered before they are ripe, and if left on the canes too long they are spoiled. A field at picking time is an interesting sight. Huge piles of tubs or earthenware vessels are ready to receive the fruit which a motley gathering of men, women, and children, the latter invariably stained almost beyond recognition with the juice, proceed to fill. When the fruit is dead ripe it sinks in the vessels and the liquor rises to the surface, thus necessitating careful handling in transfer, but it is no great detriment for preserve making, as the whole is deposited in the vats. For jam-making the fruit is generally picked without stalks, and it is a period of anxiety to the grower till the crop is disposed of. The average crop this season has been good and weather favourable for picking, though, as in the case of other small fruits, there have been complaints about prices being low.

The advice generally given for the treatment of Raspberries after fruiting is to immediately remove the old canes. No doubt this is right where circumstances permit it, but the Kentish grower with his acres, after the rush of picking is over, has many other duties more pressing to claim his attention. The Raspberries have to wait till the short days of early winter come along, and then the plantations are taken in hand, suckers are removed for planting else-

where, old canes cut away and burned, and everything set in order for the future. The general custom is to plant in rows, leaving sufficient room between for cleaning and surface cultivation, which is done by hand or with horse labour. Raspberries are gross feeders, and those who get the best results know better than to be niggardly in the way of manure. Good farmyard manure is the best, but not always obtainable, and in its absence many tons of London manure are applied to the Raspberries. Stimulants are also largely used in the shape of fish manure, guano, and chemicals with varying results, and the importance of all matters dealing with good cultivation has bearing on the success of the Raspberry crop.

Among market growers the idea of providing supports for the canes is out of the question, and therefore only such varieties are grown as are sturdy enough to be self-supporting. Norwich Wonder is largely grown in Kent for market purposes, and is a favourite on account of its sturdy habit and prolific fruiting qualities. The Kentish grower, however, is not conservative in the way of varieties, but cultivates those that suit his purpose. In addition to the above, one may see large areas of Carter's Prolific, Superlative, and Northumberland Fillbasket, all of which succeed well in the locality referred to. The period over which the stools continue in a satisfactory state of bearing depends largely on the treatment and condition of soil and situation, some plantations continuing to fruit over double the time of others.

One great bane of the Kentish grower in the way of enemies is the Raspberry weevil (*Otiorrhynchus sulcatus*), which often plays havoc among the fruit. Everybody connected with the industry knows it, and various ways and means are adopted to effect its extermination. But the Raspberry weevil, like its close relative that gives trouble in the vinery, is a tenacious creature, and encased in its hard covering is safe from the effects of insecticide. It is a night-feeding insect and destroys the fruit in an early stage. As prevention in all cases is better than cure, growers find that by destroying old canes and keeping the surface soil clean and in good condition the damage caused may be reduced to a minimum, as the methods adopted in small gardens for the eradication of pests are scarcely practicable when applied to acres.

In spite of the cry of the pessimist about bad times and poor returns, the Raspberry-producing section of the Kentish fruit-growing fraternity appears to hold its own. They have many things to contend with, but the area under this crop is gradually on the increase, and as long as the English masses buy jam, manufacturers will doubtless supply it, and the shrewd, practical men of Kent will not be behindhand in the way of fruit. G. H. H.

Repotting Cherry trees (May Duke).—The time to repot fruit trees is just when the leaves have commenced falling, at which period they suffer no ill effects from rather severe handling, and if the operation is completed so early, many fresh root fibres form before the winter arrives. The 12-inch pot is a good size in which to grow fruit trees, and if "May Duke's" Cherry tree is in a smaller size a shift may be given, taking care to loosen the tangled roots, and removing some of the old soil as well. If the tree is to be returned to the same size pot as before, the old ball of soil and roots must be reduced considerably. In either case prune the broken roots with a knife, shortening them somewhat, and repot firmly in a mixture of two parts of good loam, fibrous from choice, to one of partially decayed horse droppings, adding a sprinkling of old mortar refuse and bone meal. The tree should be watered

if the new soil is at all dry and be left in the open during the winter, merely protecting the pot with a covering of straw manure. In all probability there are only short stiff growths on the tree, and in this case no pruning is necessary, but any long straggling growths may be shortened sufficiently to restore a good balance to the tree, which should be done late in the winter rather than now. A light airy position in the greenhouse should be assigned to the tree before the buds expand. Black Tartarian would be found an admirable companion to May Duke, the tree giving a natural succession of fine fruit of the best quality.—W. I.

NOTES OF THE WEEK.

Carnation Nox is the darkest of dark crimson or crimson-maroon shades, too dark indeed to produce really good results in the garden, as beyond a certain limit these exceedingly dark forms are more or less gloomy and forbidding—certainly the reverse of bright and attractive.

Centaurea ruthenica.—The yellow Cornflower, though distinct enough in its heads of flowers, is not one of the best habited of hardy plants, yet it is one of those plants that specially good culture considerably improves, and better still if grouped in a free manner in an isolated position rather than with the ordinary things in the border. In this way the plant is of more than passing interest and beauty.

Podophyllum Emodi.—The two seasons of the year when this plant is conspicuous are when the handsome foliage is fully developed, or later in the year when the brilliant scarlet egg-shaped fruits have perfected their fine colour. That so fine a fruit should result from this plant is of itself an interesting matter, and still more so when in full colour, for then it is a source of considerable attraction.—E. J.

Physostegia virginica alba.—Though by no means a new or even a scarce plant, this is not made so much use of as its merits justify, for it is quite a showy subject when freely grown in good soil. It is quite among the hardest of border flowers, producing its spikes of white flowers somewhat freely. The plant is benefited by being divided every second year, replanting only the youngest and freshest portions.

Calandrinia Tweedi.—Judging by the behaviour of a group of this distinct plant in the rock garden at Kew, there would appear some likelihood of its being a profuse flowering species when more established. Should this prove to be the case, and the perfect hardiness of the plant also ensured, it will be a valuable addition to good alpinists. The blossoms are of good size and possess quite an uncommon tone of colour, even among the variable shades of a good collection of choice subjects.—E. J.

Abutilon Golden Fleece.—Probably no other member of this family can boast of so fine a colour or of being so great a bloomer, for it is in this respect well-nigh perpetual, provided a greenhouse temperature be given it. During the summer months, and, indeed, far away into the waning months of the year, the plants, when covering space on the glass roof, are one mass of bloom incessantly, the fine colour, apart from the endless number of drooping blossoms, being quite ample to attract attention.

Rose Grace Darling.—Quite early and moderately late also in the year, this is a fine and telling Rose in the garden, particularly where a large bed may be given wholly to this one variety. The blooms are both full and very handsome in appearance, though it must be confessed that the colour is not the best to endure the strong heat of a summer like the present. At the same time, the profuse flowering of the variety is enough to make it worthy of a special position where the intense heat would not reach it.

Lobelia and Phlox.—Both subjects here mentioned may be regarded as of a decidedly moisture-loving nature, which is one reason why they may with impunity enjoy or share each other's company. Yet, apart from this, an excellent effect may be secured by grouping, say, a good dark-leaved form of *Lobelia cardinalis* with

a pure white *Phlox* of the herbaceous section. Equally satisfactory is the fact that both plants flower at much the same time, or at least sufficiently near that the desired result may be secured. To be quite vigorous and free, however, the plants should not be far removed from moisture.

Colchicum byzantinum.—This Meadow Saffron has been the third in order of flowering in my collection this year. A clump is now exceedingly effective and beautiful with the large, prettily-coloured soft purple and white blooms. It is sturdier in habit than many of the genus and less liable to injury from stormy weather. Like all the other Meadow Saffrons it requires a "carpet" to show it to advantage. Some of the Mossy Saxifrages are well adapted for this purpose, and many other plants will readily occur to those acquainted with the dwarfier plants.—S. ARNOTT, *Carsethorn, by Dumfries, N. B.*

Mutisia decurrens.—Last year I sent you some blooms of *Mutisia decurrens*. I now send you three blooms enclosed with this note. The early frost and winds destroyed the young shoots, but, notwithstanding, I have had blooms for the last eight weeks. It is a pity this plant is not grown more extensively. It has stood five winters with me, and with no protection. The colour is unique at this time of year, being not yellow, but a decided orange. I am exposed to every wind, so my plants are not so good as those at Easter Duddingstone (the late Mr. Jenner's). But surely is it not worth growing?—J. MOWBRAY WATSON, *Wintonhope, Ravelston Dykes, Edinburgh.*

Bocconia microcarpa.—I send a specimen of *Bocconia microcarpa*. It is very like *B. cordata*, of which also I send a specimen to show the difference. Though similar, *B. microcarpa* is really distinct, having rosy buds, which give a pretty appearance, and leaves which are rather less cut on the margin. I received the seed from Messrs. Vilmorin-Andrieux and Co., who gave a cut in their supplementary catalogue of last year, which I enclose. They do not give the country, and the name does not occur in the "Index Kewensis." The plant appears to be a good one and a distinct acquisition. There is a fine specimen in the herb ground at Kew.—R. IRWIN LYNCH, *Botanic Gardens, Cambridge.*

Helianthus multiflorus maximus.—This is perhaps not only one of the easiest grown of hardy Sunflowers, but certainly one of the boldest and most handsome. The large single flowers are also of a distinct shade of yellow, paler than in the other single forms, yet distinctly pleasing and showy. Freely grown, the plants attain from 6 feet to 7 feet high, and in its bold self-supporting character has few rivals among hardy herbaceous plants. Like all others of the Sunflower family, this one delights in a deep and rich soil, which its great vigour speedily exhausts if not replenished. By rooting a few cuttings now and then the old roots may be discarded and a young, vigorous stock retained. Much the same results ensue when the younger or outer shoots of the clump are removed and planted in fresh ground.

Zauschneria californica splendens.—The plant here mentioned would suggest an improvement on the typical species, which, when well grown, is perhaps one of the most brilliant of all hardy flowers. But it prefers a deep though light and rich soil in which it may the more freely produce its stoloniferous shoots, and thus take care of itself during hard and trying winters. It is not usual for the plant to perish outright in warm, well-drained soils, but in the reverse, and where clay is too freely incorporated, the plant is less hardy. Yet it is so brilliant and effective, spreading itself into good patches where it can travel quickly, that it is worth making preparation for. The variety *splendens* is somewhat later in flowering, and has more woolly and therefore very distinct foliage. Indeed, so well-marked a plant would appear well-nigh worthy of specific rank, though what constitutes a species is a problem difficult to solve, and by no means easy to define.

ROSE GARDEN.

ROSE SOUVENIR DE LA MALMAISON.

THE Rose tree illustrated is worked as a dwarf standard on the Brier. The stem is only about 2 feet high. The girth of stem is 1 foot, but at the graft measures 1 foot 10 inches round. Total height of tree, 9 feet; total width through, 13 feet. At the time the photo was taken (middle of July) it had over 300 expanded blossoms. The tree is very healthy,

was pruned back rather hard at the end of March.

GEORGE W. F. HARDY.

Loughton Lodge, Loughton, Essex.

Rose Archduke Charles (China).—This is a variety of remarkable variability. Sometimes the expanded flowers are pure red; at others the centre petals are light bluish, relieved with white, and the outer petals of rich velvety crimson. It is fairly double, a really good grower, and altogether an excellent China Rose, being most certainly too good a variety to be lost sight of. Though classed as a China, it appears to be very

considerable. In Waltham Standard an excellent summer and late-flowering red Rose has appeared, every growth being crowned with buds and blossoms. I should say, with the exception of General Jacqueminot and Ulrich Brunner, there is no better late-flowering crimson variety than this one. But this perpetual character is only one of its good points. In its perfectly-formed blossoms and substantial petals we have an ideal show Rose. The petals are beautifully arranged in a circular outline, and slightly recurve at the edges, and the high centre is just the exhibitor's standard of perfection. This Rose appears to be intermediary between Star of Wal-

Rose tree Souvenir de la Malmaison at Loughton Lodge, Essex.

and has been free from both aphids and caterpillars, and is now making good growth for second crop of bloom. It is a general impression that standard Rose trees are very short lived, but this tree must be at least thirty years old. My soil is a stiff, clayey loam. The view you have selected, viz., the west side, does not show nearly so many blooms as the east side had, but makes a better photograph, as shrubs and trees in the background interfered with the detail on that side. The tree

nearly a Tea-scented, differing greatly from the Chinas in its erect habit of growth. One would take it to be the parent of that beautiful Rose Duke of York, as it has many of the peculiar variations in colour of this now very popular kind, but the two varieties are perfectly distinct, and both should be included in every collection of garden Roses.

A fine new autumnal Rose.—As a writer remarked recently, our collection of good autumnal Hybrid Perpetuals is very meagre, and when we do receive a good one its value is

tham and E.Y. Teas. It is, however, a far better grower than the latter, and most fragrant. I consider it a splendid Rose both for the exhibitor and for the novice, and I predict for it a prosperous future. PHILMILL.

Rose leaves eaten (*M. E. Champion*).—The holes in your Rose leaves are rather peculiar. Some are undoubtedly, I should say, caused by the grubs of sawflies, and I found two small ones about a quarter of an inch long on the leaves. They had evidently caused the small white patches. The larger holes and notches are, I

believe, caused by a fungus belonging to the genus *Phyllosticta*, or *Cercospora*. The holes in your *Begonia* leaves are certainly caused by one of these fungi, but I cannot be quite certain of those in the Rose leaves. The fungus causes the leaf to wither at a certain point, and gradually spreads; the withered part drops out, leaving a hole, which gradually increases as the fungus destroys the leaf. This I believe to be the course of things. As to the little insects that you describe, that are so nimble that they can neither be caught by the fingers nor touched by syringing the plants, they are nearly allied to the common froghopper. They may be captured by holding a piece of cardboard, or calico stretched on a light frame, an old Palm-leaf fan, or anything of a similar nature, newly painted or tarred, under the leaves, so that when the insects are disturbed they may jump on to them and thus be caught. —G. S. S.

DWARF TEA ROSES WITH RED FLOWERS.

PERHAPS these are not so much admired as those kinds of more delicate shades, but red Teas have their especial value, such as for winter flowering, when a little bright colour is always welcome, and also for garden decoration when harmoniously dispersed. The most beautiful of all is

PAPA GONTIER.—It is a charming variety in the bud state, with flowers of a lovely clear rosy crimson colour, of long shape. As a winter Rose it is unsurpassed in its colour. Although it may be grown in great perfection in this country, it never approaches the great vigour that it does on the Riviera. I believe Lord Brougham has immense quantities of this Rose in his beautiful garden there. The next best is certainly

FRANCIS DUBRIEUL.—Its blossoms, especially in the bud state, are most beautiful in form. The colour is velvety crimson, reflexed with cerise, and there is a peculiar and attractive black velvety shading about this Rose that at once commands attention. It is certainly the best Rose of its colour, but for cutting it is rather disappointing, as the blossoms have a peculiar manner of bending over, which mars an otherwise fine Rose.

SOUVENIR DE THERESE LEVET is frequently met with in show boxes, and is beautiful when well developed, but it requires much thinning of the buds and side shoots to get it to this perfection. The outer petals are like butterfly wings, and give this Rose a very uncommon appearance. The colour is bright red with a deeper shading. Its growth is very slender, but fairly vigorous.

PRINCESSE DE SAGAN resembles an improved China Rose. Its colour is a very intense crimson-scarlet, but the individual blossoms are not equal to those of the last-named variety. It is, however, a better garden Rose and most decorative, being exceedingly free-flowering.

MARIANO VERGARA would doubtless make a good show flower. It is, however, not so vigorous as one could wish. The colour is very brilliant magenta-red, and it does not fade.

MME. LOUIS LAURENS is fine in the bud, which is of great substance and elongated. It is far too good a Rose to be discarded. The only bad quality is that the centre petals of the expanded flowers overlap. If it were not for this it would take a prominent place, for its petals are of great substance. Growth is vigorous, and the colour a deep red, with a bronzy hue sometimes pervading the centre of the flower. The defect of the centres in the open flowers is not manifest in the beautiful buds.

GENERAL SCHABLIKINE.—This is a small Rose of the type of the red Safrano. Its flowers are coppery red, and it is useful as a garden variety.

The last variety to notice, although a Hybrid Tea, is too good to be omitted here, and his one is

PRINCESS BONNIE.—It is of delicious fragrance, extremely free-flowering, and the habit of growth

and style of flowering are very distinct and attractive. The colour is a brilliant and rich crimson, and altogether it is a Rose everyone should possess for cutting. PHLOMEL.

THE MACARTNEY ROSES (A. BRACTEATA).

THESE very beautiful and distinct Roses have been most gay during the month of August, and they really deserve more consideration. It is true they are not quite hardy, and doubtless a south or west wall, not very high, is the best place for them. Failing such a spot, they may be grown in a sheltered border, and if moulded up each winter they will come out as fresh as ever the next spring. The type was introduced from China about the end of last century, and even to-day there are few single Roses more beautiful. Then again, the late flowering period of these Roses is a valuable trait in their character, for there are few single Roses that blossom so late. Many growers prefer the double kind *Maria Leonida*, but I think the single white is the general favourite. Its blossoms are produced singly, and are fully 2½ inches in diameter. The buttercup-yellow stamens are very numerous and are quite 1 inch in diameter, giving the flower a beautiful appearance. The growths have a downy appearance, and the foliage is very small and waxy. The leaves are produced in sevens and nines, and there are two or three sharp prickles at the base of each leaf-stalk. From a close inspection of this Rose I am inclined to think that the new *Wichuriana* is the offspring of it, but the latter is much hardier, and, as is well known, has an extraordinary power of producing long running shoots.

Maria Leonida has delightful Tea-like buds, but only about half their size. It resembles *Rubens* in colour. The calyx is very quaint, reaching, finger-like, almost to the top of the petals, and covered with tiny reddish hairs. The expanded flowers are double, but not extra double. When fully developed they display a small bunch of crimson anthers, and there are a few petals overlapping the centre, which look exactly as if a small button had been inserted. The habit is not so trailing as *Alba simplex*, and the foliage is larger. The growths, usually from 2½ feet to 3½ feet in length, are crowned with a bunch of flowers at top. Sometimes these growths produce from twelve to fifteen laterals, each bearing one crown blossom. This variety seems to be closely related to the *Clynophylla* Roses (*R. lucida*). As conservatory Roses these Macartneys would be very interesting, for they are practically evergreen when removed from the ravages of frost. P.

The Victor Verdier race as autumnals.—

Perhaps we may overlook the deficiency of fragrance in this numerous family when it is remembered how very excellent they are as autumnals. Just now the originator of the group is producing its blossoms in great profusion. It is generally conceded that this Rose has an admixture of the China or Tea-scented, and is probably a hybrid between these classes and the Hybrid Perpetuals. Nearly all the smooth-wooded H.P. Roses can claim it as a parent. It produces seed most freely, and some marvellous variations of colour are seen in its progeny. The popular *Mlle. Eugénie Verdier* is one of them, and a lovely Rose it is with its light flesh-coloured flowers. On the other hand, *Countess of Oxford* is as distinct from the latter in colour as it is possible for two Roses to be. This Rose has given us one of the best light-coloured varieties we possess, namely, *Pride of Waltham*, and for show purposes or for the garden this Rose has entirely superseded *Marie Finger* and *Mlle. Eugénie Verdier*. Another lovely kind is *Mme. Bois*. The colour is a delightful light rose tint, deeper than *Pride of Waltham*, and quite distinct from any other Rose. *Etienne Levet* is yet another of the family, and although its growth is dwarf and stumpy, the immense flat blossoms of a pleasing carmine shade

are very much valued by exhibitors. Here again we see the remarkable tendency the *Victor Verdier* race has for sporting, for *Duke of Fife* owes its origin to *Etienne Levet*. All of these kinds are well to the front in the autumn months, and give just the shades of colour required to intermingle with the more delicate colours of the Teas and Hybrid Teas. Of course, it is well known that the beautiful autumnal *Captain Christy* originated from *Victor Verdier*, and still more recently *Lady Mary Fitzwilliam*. The far-reaching influence of this latter Rose will be seen for many a day, and *Mme. Abel Chatenay*, *Mrs. W. J. Grant*, *Antoine Rivoire* and *Souvenir de Mme. Eugénie Verdier* are only a few of what are yet in store for us from this marvellous hybrid.—P.

FLOWER GARDEN.

TROPEOLUM SPECIOSUM.

I TRUST Mr. Ewbank will forgive my delay in referring to his interesting "Shrub Notes" on p. 113 of THE GARDEN for August 13. I have been very busy and have not had time to put together any remarks upon the subject. Mr. Ewbank's notes entitle them to more than a hurried reply. There is no real difference of opinion between us regarding *Tropeolum speciosum*. My short note was nothing more than an attempt to induce people who have dry gardens and have hitherto failed with this *Tropeolum* to persevere in trying to establish it. There are comparatively few gardens possessing the precise conditions of that at St. John's Vicarage in the Isle of Wight, and those who possess such gardens cannot do better than follow Mr. Ewbank's advice and prepare accordingly. One can hardly avoid generalising at times, and Mr. Ewbank will perhaps pardon me saying that his description of Scotland as so often bathed in mist is only true of a comparatively limited portion. In that portion, however, *Tropeolum speciosum* is unusually brilliant, whether by reason of the moisture of the atmosphere or because the vivid colouring shows well in contrast to the gloom which frequently prevails. This it is only fair to admit. I am far from denying the preference of *T. speciosum* for moisture and rich soil, but what I wished to point out was that these are not absolutely indispensable, and that when established it will grow vigorously and give satisfaction under other conditions. I have in my mind several examples besides the one cited in THE GARDEN of July 30. Two or three of these may be referred to. At present on the west front of a farmhouse, growing in hard gravel, a good specimen is covered with flowers of the brightest description. When I first saw it, about a month ago, I could hardly believe that it could be the justly admired *T. speciosum* until I made a closer inspection. Some four or five years ago, in going through the garden of a Scottish manse (out of the region of frequent mists, let it be said), I was delighted with the mantles and wreaths of the Flame Flower on the old Yew trees in the garden. The soil was so robbed by the roots of the Yews that it was almost dust-dry, yet the *Tropeolum* was full of flower. In another garden it was planted with an east exposure in gravel on a sandy subsoil, with the result that, while it took years to establish, it now grows and flowers freely.

I am writing also with some personal experience, after having for some years made several unsuccessful efforts to grow the Flame *Tropeolum* in my own garden. At various times I have procured and planted it, only to see it fail to come up or make weakly growth, then dwindle away and die. Sometimes slugs were

responsible for the failure, but more frequently the cause was the dryness of the soil and the fact that the plants did not become thoroughly established. One spot in particular in which I had a wish to grow this fine climber has given me a good deal of trouble, which makes the pleasure of victory all the greater now that it is within reach. An old Hawthorn tree is retained for shelter to the garden, and as from its position it is necessary to keep it partly clipped, it needs climbing plants to relieve its stiffish outline and brighten it up in the later months. A Honeysuckle clambers up, and for some years I have been trying to associate with this the *Tropaeolum*. I have failed up till now, but a couple of shoots which came up for the third season last year have been carefully nursed until one of them reached some 4 feet high, the other failing to reach more than half that height. The former made a few buds, but frost came too early to allow them to expand. This year the plant has sent up shoots a yard or two away, and the main growths on the tree have grown much more vigorously, and are rewarding me with a promise of full bloom. From what I have seen of the plant elsewhere, I am satisfied that the hill of difficulty has been surmounted, and that I shall, should life be spared, have the pleasure of enjoying the flower in greater beauty in years to come.

My former note was penned with a desire to encourage those who have experienced difficulties similar to my own. Our good friend's notes were most welcome. We have, I believe, the same object in view. Whatever divergences may exist are largely due to the different climate and conditions in the Isle of Wight, and the expression of our respective views may, one hopes, only lead others to refuse to admit failures in growing *Tropaeolum speciosum* without renewed and continued trial.

S. ARNOTT.

Cursithorn, by Dunfries, N.B.

GARDEN ENEMIES.

WHATEVER else may be set down as a special feature of the present year, I think it is safely a record season for the numbers and pertinacity of garden enemies; their name is legion alike in variety and number. I have not counted all, but a brief account of those that came under notice in one particular day will indicate our present troubles. Walking along an old slip garden, the wall of which is chiefly covered with Plums, I noticed something literally tumble from a tree some distance in front, and on hurrying forward found it was a big old rat that had been walking off with the Plums, some which remained on the tree bearing the marks of teeth. It is the first time I have had them run up wall trees after fruit, although in previous years they have visited the bush Apples. Writing of Apples reminds me to note that jays and blackbirds have already been troublesome, and despite the fact that some were shot and suspended from the trees, they spoiled a lot of Quarrendens, Mr. Gladstone, and Duchess of Oldenburgh. We shall have to watch the best sorts carefully, and in the case of dwarf trees throw a net over them if possible. In the early days of the Peaches and Nectarines they were with difficulty kept free of aphid and red spider, and now, as they are approaching the ripening stage, we have to contend with earwigs, wasps, bluebottle flies, and ants. The two first named are, fortunately, the easiest to get rid of: fortunately, because in the majority of cases they are responsible for the commencement of the mischief the others are only too ready to continue. With the earwig the great point is to be early in the field with the Bean traps and endeavour to clear them out, at least to a great extent, before the fruit approaches the ripening stage.

Wasps are strongly in evidence despite the fact that comparatively few queens were seen in the spring; as in the case of earwigs, there is nothing like being early in the field against them. We have already found some thirty nests in the immediate neighbourhood of the garden. The flies are in such numbers that they quickly demolish fruit when it is once tapped for them; bottles containing beer and sugar lure them to destruction, and many are taken, but they prefer a ripe Peach or Nectarine to the intoxicant. All winged insects, as butterflies, moths, flies, and gnats in endless variety are extraordinarily numerous, and in the case of the last three named there are many forms I have not previously noticed in this locality. One of our worst enemies—red spider—has been very troublesome all round this neighbourhood, and where labour is somewhat scarce it is almost impossible to keep it in check, and, owing to the absence of rain, it

from young shoots, creating new combs, much may be done to strengthen a stock. But seeing how readily fine plants are produced from seed, it is wisest either to raise from seed yearly or else purchase tested yearling tubers.—A. D.

LILIUM COLCHICUM.

The accompanying photograph of *Lilium colchicum* shows its growth in a garden where the soil is a heavy loam and the climate one of much moisture. It has yearly increased in quantity and height, though receiving no other attention than a slight winter top-dressing of old manure. It is alike beautiful in the radiance of the morning sunshine or in the soft stillness of the twilight hours, for in the "North Country" night does not draw her dark mantle across the summer skies, but leaves the western heavens aglow, till the pale light in the northern horizon proclaims the sun's swift course beneath.

Over the wall clambers the Sweet Jessamine not yet in bloom, but, half tumbling down, makes of its dark leaves a dusky alcove, against which *Lilium colchicum* stands forth erect and stately some 5 feet high, its stems set closely with luminous blossoms in colour like fresh plucked Lemons. The petals as they lie folded together before unclinging have a deep purple stain where they join the flower-stems, and the point of each is in like manner tipped with dark purple. As the blossoms expand the petals curve upwards, displaying the dark markings beneath, and leaving visible the purple-capped stigma surrounded by the dangling orange-red anthers. It is a lovely flower, whether beheld glowing in the sunlight, or cool and pure like moonbeams in the dusky hours.

Lilium colchicum. From a photograph sent by Mrs. Lawrenson, Tobacora, Antrim.

NOTES ON HARDY PLANTS.

Dianthus Knappi. What a long time this new Pink continues to bloom. You cannot but notice it because, though small, the flowers are of the clearest canary-yellow. I fear, however, that to the minds of many the otherwise pretty parts of this species may be discounted by the fact that the flowers are in clustered or congested bunches, on longish scape-like stems, in the way of *cinnabarinus*, *carthusianorum*, and *cruentus*, and yet the plant has a pretty habit, not to say elegant. The grass is rather long, thin, and narrow.

Primula Rusbyi.—This is the latest and sweetest of all the Primroses: its deep crimson-magenta flowers are almost as welcome in the latter days of August as any of its sisters in spring. Not only is the colour striking, but the under sides of the corolla are just the same deep shade. The "eye" is old gold colour, and the mealy edged calyx divisions are of marvellous beauty, owing to the silvery edges being contrasted with the succulent leather-brown calyx. It is a very distinct species in every way and belongs to the comparatively small group as yet found only in America. You cannot grow a more charming kind: and besides, if you get it to do well there is scarcely another hardy alpine you would have

is still strongly in evidence. It has paid particular attention to Gooseberries on the trellis and to plantations of Violets. E. BURRELL.

Clarmont.

Endurance of Begonias (Clarmont).—There can be no doubt but that Begonias, like many other plants, do deteriorate somewhat with age, because of their peculiar nature, but still very much depends on the variety and its natural habit or constitution and upon the way treated. Such a fine tuberous variety as the scarlet bedding *Worthiana*, though increased by myriads yearly through cuttings, is as robust as ever. Much depends on the treatment the plants receive in the summer, which, if good, enables them to strengthen the root-combs, and the treatment the combs receive in the winter. Then by propagation, both in the late summer and in the spring

more cause to be proud of. I have grown it for twelve years and find it starts and flowers late, grows rapidly, but increases by offsets slowly.

Houstonia purpurea.—Do not be induced to plant this, however tempting its family name may seem. The pretty creeping *H. serpyllifolia* and the lovely "Bluets," or *H. cœrulea*, with its variety *alba*, are just as good as good can be, but the present plant is coarse and grows over a foot, and has dingy flowers.

Conandron ramondioides.—A few flowers are now open on the plants which stood out of doors all last winter. I think this is at least interesting, though the winter proved so mild, as it points to the possible chances of this lovely plant enduring the open-air culture the year round in many parts of our islands.

Woodville, Kirkstall.

J. Wood.

THE CLEMATISES.

(Continued from page 138.)

SECTION V.—*C. LANUGINOSA*.

C. LANUGINOSA is the best of the large-flowered Clematises. The forms are characterised by their buds, which are large and woolly, as are also the peduncles and the young leaves. They are quite a distinct section, though allied to the *azurea*.

I have one of the first species which has been in my collection for a number of years. Such species are becoming very rare. I give a description of it here with that very old variety, *C. lanuginosa pallida*, and that of another superb form which I have had for at least ten years, and have known as *C. lanuginosa* species.

C. LANUGINOSA (Lindley).—In 1850 the woolly Clematis was sent to England by Fortune. It flourishes in the north of China on the Chekiang Mountains, near Ningpo, on the hillsides, in light and rocky soil, where its large handsome blue star-like flowers may be seen upon the tops of the bushes. In the spring of 1852 a plant bloomed with Messrs. Standish and Noble. The strong, vigorous stems scarcely attain a greater height than 2½ yards to 3¼ yards. The foliage is of a greenish white. The flowers are fairly large in size and in shape oval, terminating in a point; they are woolly, especially on the under side. The inflorescences are in threes and terminal. Instead of a rather short spring bloom like that of *C. azurea*, *C. lanuginosa* begins to bloom in June and July, and its flowers continue throughout August and September. These are very large, 6 inches to 8 inches in diameter sometimes, of a handsome pearly grey-blue or lilac colour, and star-shaped, with lozenge-shaped pointed and recurved sepals.

C. LANUGINOSA VAR. *PALLIDA*.—This differs from the species only in its paler flowers. About ten years ago there came to me under the name of *C. lanuginosa* species a splendid woolly Clematis, characterised by thickly-set foliage, composed of rounded cordiform leaves of a whiter green colour than the type, as well as being more woolly, especially underneath. The flowers were of a bright lilac satiny blue, of a more intense shade than in the type, and were composed of larger, rounded and more recurved sepals, which combined formed a superb rose of from 4½ inches to 6 inches diameter, the numerous and very clustering flowers forming at a height of over a yard from the ground an enormous and magnificent bouquet. I have still in my possession the first species, which is now nowhere else to be found. It differs perceptibly from the *lanuginosa* of commerce in having the sepals smaller and more pointed and the leaves only slightly cordiform.

The introduction of *C. lanuginosa* brought about a veritable revolution amongst amateurs. Already attempts had been made to hybridise the *Viticella* with the *azurea*, but the new arrival from China at once monopolised the

attention of hybridisers and was the cause of the inclusion of the Clematis family within the domain of horticulture.

In France and England repeated crossing with *C. Viticella*, *azurea*, *florida*, *Fortunei*, *Standishi*, *integrifolia*, *Hendersoni*, &c., have produced a very large number of varieties, in some of which are to be found the long-flowered vine stems of the *Viticella*, and in others the ample flowers of the *Viticella*, but instead of only a spring bloom of no great duration we have now flowers from May and June through the summer and the earlier part of autumn. Prolonged vegetation and successive bloom during several months are, in fact, the distinctive characteristic of the woolly Clematis.

In speaking of the hybrids, I intend to give the nomenclature of the large number of those that belong to the *lanuginosa*, and they are certainly the handsomest of the entire race. *C. lanuginosa* does best in a northern aspect and peaty soil. In such a situation it reaches its fullest vigour, and its flowers last longer and preserve their freshness better.

SECTION VI.—*ATRAGENES*.

I.—*THE ATRAGENES PROPER.*

The *Atragenes* are charming and graceful spring Clematises, but are little known and not often seen in gardens. Now-a-days they are seldom met with anywhere except in botanic gardens. Nevertheless, they have a true garden value. Their moderate size adapts them for cultivation in pots, and their pendent bell flowers—blue, rose colour, or white—are most attractive. I have cultivated four species, viz. :—

C. ALPINA (Mill.), *ATRAGENE ALPINA* (Linn.).—Among the first was the alpine Clematis, a native of the Alps and of Southern Europe, growing at an elevation of 2000 feet to 4000 feet. The stems, which at first are stained red, rise to a height of between 3 feet and 6 feet. The flowers are a bright and delicate blue, and open from the centre of the bud. The alpine Clematis is hardy and most likely to succeed when planted in a northern situation in peaty soil.

C. AUSTRIACA, *ATRAGENE AUSTRIACA* (Scop.), *A. MACROPETALA* (Hort.).—This species, which came to me under both these names, is allied to the preceding, differing from it in the bell-shaped flowers, which are larger and more pendent. The stems, with their numerous offshoots, are not so high, and the leaves shorter and more regularly indented. The petals are of unequal size, and resemble a semi-double flower as they increase in size. The flowers are a violet-blue of a deeper shade than in the preceding species. Like those of the alpine Clematis, they open in April and May, and sometimes in August. Under the name of *Atragene macropetala*, Walpers describes a Doorian species which, with its numerous oblong and pointed petals, the exterior ones of which are almost as long as sepals, would appear to be the same as *Atragene austriaca*.

C. SIBIRICA (Mill.), *ATRAGENE SIBIRICA* (Linn.).—I have cultivated a Clematis under this name, and it resembles the preceding one in all respects save in having white flowers. It is a real *austriaca* *alba*, with perhaps a more vigorous growth. These two last have bell-shaped flowers, blue or white, are very graceful plants and more beautiful than the alpine Clematis.

C. VERTICILLARIS (De C.), *ATRAGENE AMERICANA* (Sims).—This, although a climbing plant, is quite distinct from the preceding. The flowers resemble those of *C. austriaca*, excepting that they are purple or purplish in colour. This species, which is not now met with, and which I have lost, is extremely interesting.

II.—*ANEMONEFLORA*.

Under this name I do not hesitate to commence a second paragraph in the section of *Atragenes* for the sake of placing these two

Asiatic species, one very common and very much liked, *C. montana*, the other rare and rather curious than beautiful, *C. barbellata*. *C. montana* was classed by De Candolle with the *calycinae*. The mountain Clematis has the flowers crossed like the alpine Clematis. *C. barbellata* has pendent flowers and pointed sepals like those of *C. austriaca*.

C. MONTANA (Buchan), *C. ANEMONEFLORA* (Don).—The mountain or Anemone-flowered Clematis is a native of Nepal. At the present day it is one of the most largely grown of the Clematises, and it seems likely to take the place of the old sweet-scented Clematis (*C. Flammula*) as an ornament for palisades, &c. It mounts to a great height on trees, and for this reason may be used with advantage and with charming effect in parks and large gardens. *C. montana* blooms in May. It is also strikingly handsome for its fine dark foliage. The leaf is indented. It is truly the Clematis of the "month of Mary," and well deserves to be the favourite it is.

C. BARRELLATA, *C. NEPALENSIS*.—This species is as rare as the preceding one is common. It was first raised from seed in 1851 at the Botanic Garden, Glasnevin, near Dublin, where it flowered in 1853 or 1854. In leafage it resembles *C. montana*, but differs from the latter in its flowers, which are of a brown or russet tint, and are of a pendent, bell shape, with long pointed sepals. I have cultivated it and seen it in flower. The colour of the flowers resembles that of the *Asarum* flower. It must not be confused with the *C. nepalensis* described by De Candolle as nearly allied to *montana*, and belonging also to the Himalayan region. De Candolle does not mention *barbellata*, which was not introduced when he published his "Prodromus."

SECTION VII.—*CALYCINÆ*.

The *calycinae*, or, as I prefer it, the *caliculae*, are the green Clematis of the Mediterranean region. In our climate they winter in the open air, and except in a very severe season are ever-green. After resting in August, when the leaves become yellow, they start into growth at a time which corresponds to our autumn, and the blooms come some time between December and March, according to the season. Though not strikingly handsome with their yellow and yellow-green tints, the flowers are really interesting, coming as they do at a time when Nature is bare and the cheery green of the leaves stands out in graceful relief. The caliculae are very vigorous climbers, able to rise several yards and cover large spaces.

C. CALYCINA.—This originally came from the Balearic Isles, Majorca and Minorca. It is the type of the group, and distinguished from its congeners by its delicate and much-divided foliage, which in the sun acquires a reddish tint, and by its rather pretty bell-shaped yellow or china-red flowers. I have grown a variety of *C. calycina* that had a larger and less divided leaf.

C. CIRRHOSA (Linn.).—This has the leaf less divided than the preceding and composed of three oval indented segments, the colour a handsome glossy green. The flowers are greenish. A bushy plant, it is valuable for covering walls with the aid of wire. It is a native of South Europe and of the islands of Crete, Corsica, Calabria and Sicily.

C. SEMITRILORA is nearly allied to the preceding. Its handsome glossy green leaves are for the most part formed in three lobes, and some are entire. They are indented and resemble in appearance those of the Hawthorn. The flowers are a greenish white and of a fair size. Its origin is ascribed to Southern Spain, but there can be no doubt but that, like the species of the same group, it belongs to the whole of the Mediterranean region. When on a visit to Jerusalem in 1890 I met with it on the summit of Mount Tabar.

These Clematises are not enough grown. In winter the flowers are not to be despised for

bouquets, and grown in pots they would when in bloom find a ready sale.

SECTION VIII.—UNCLASSIFIED CLEMATISES.

There will always be a certain number of species and varieties which cannot be classed amongst the preceding sections. It is useful to reserve for them at least a provisional place until having been better studied and become better known. They are either attached to old groups, or, by their relationship with new species of which they were the first introduced members, they constitute new sections of the already richly endowed race of cosmopolitan climbing plants which are found in all parts of the globe. Yet another work remains to be done, and that is to classify the numerous hybrids and make a distinct section of them from the natural and type species, and not fall into the error of confusing with these the mere results of crossings, or, on the other hand, place amongst the hybrids Clematise reproduced from seed and possessing incontestably the characteristics of the species. In this section I place the five following Clematis: *C. corulea odorata*, *C. Jackmani*, *C. Hendersoni*, *C. crassifolia*, *C. smilacifolia*.

C. CERULEA ODORATA (Hort.).—I have known this Clematis for more than thirty years and I have it now. I have often seen it in fine condition on the face of a south wall in the late M. A. Pellier's collection. It is not a climbing plant. It has straight and spreading stems rising to a height of 4 feet to 6 feet—seldom 8 feet. The bloom is borne upon a kind of panicle. The leaves are almost glaucous; the flowers small, and are composed of four narrow sepals, open, and in colour a fine violet-blue. They exhale a decided odour of vanilla. The above description tallies in all respects with that of the *C. Poizati* (Hort.) (Seringe's "Flore des Jardins," vol. iii., 1849) obtained by M. Poizat, of Villeurbanne, near Lyons. *C. corulea odorata* was so-named by M. Bertin the elder, Versailles, who obtained it from M. Poizat (*Revue Hort.*, 1877). This Clematis is nearly allied to *C. violacea* (Alph. de Candolle). I have never seen it otherwise than sterile, and this is also my experience of the present year. There is no doubt that *C. cerulea odorata*, which is identical with *C. Poizati*, is a hybrid of a (probably) paniculated species and a blue species of the *Viticella* group, and therefore I believe M. Alph. Lavallée to have been in error in calling it a species and a type under the name of *C. aromatica*.

C. JACKMANI (Hort.).—This English hybrid Clematis is at the present day classed as one of the most beautiful. It made its first appearance between the years 1864 and 1866. Messrs. Jackman and Son, of Woking, introduced it to commerce as having been obtained by crossing *C. Viticella* with *C. Hendersoni*, or, as I have elsewhere seen, *C. lanuginosa* with *C. Hendersoni*. In any case *C. Jackmani*, with its flowers of fine and intense violet-purple-velvet colour, would seem to belong much more to the *Viticella* section than any other. Towards 1880 Dr. Savatier discovered in Japan a species of Clematis, which, in the opinion of M. Lavallée, is identical with Jackman's Clematis. This species from the hills of Hakone, in the island of Nippon, has been named *C. hakonensis*. It has blue flowers, is figured in M. Lavallée's book, and classed among the *Viticella*. Whether a case of chance resemblance or one of identity between Jackman's Clematis and the Japan species, this Clematis has now been reproduced under its quite distinct type in a large number of new hybrids, and in fact it constitutes a race which ought to have a place side by side with the *Viticella*, the *floridea*, the *azurea*, and the *lanuginosa*.

C. HENDERSONI (Hort.).—I have already spoken of this Clematis when describing *integrifolia* and its different forms. *C. Hendersoni* was introduced to English gardens as the result of crossing *C. Viticella* with *C. cylindrica*. It has flowers

similar in all respects to those of *C. integrifolia*, whose relationship is much more evident. Although almost invariably sterile, *M. Decaisne* nevertheless classes it as a species under the name of *C. Eriostemon*. He adheres to this name, and makes it the type of one of his sections. To me it is merely a hybrid of the *integrifolia* group.

There yet remain two well-marked species of uncertain classification.

C. CRASSIFOLIA.—This I have often seen in the late M. Foulard's garden, and it appeared to have many of the characteristics of the Australian Clematis, notably *C. aristata*. Is it identical with *C. eoriacea* of New Holland? In any case it came into the market as a native of Japan. It is a greenhouse plant characterised by thick, strong leaves of a fine green and white flowers on little panicles.

C. SMILACIFOLIA (Wallieh).—This is a magnificent climber, distinguished from every other by its habit and enormous growth and its large, entire, oval, and heart-shaped, strong and glaucous leaves, which in the young state are marked with white and of a bright green. The flowers are on the outside of a russet-brown colour and woolly, and on the inside a deep violet, almost black. This handsome species I saw flowering in November, 1852, in a greenhouse belonging to the late M. Bougard. It is a native of Nepal, and was brought to Belgium from Java, where it flourishes on the mountains, which accounts for its doing well under glass.—Dr. JULES LE BELE, in *Bulletin d'Horticulture de la Sarthe*.

THE NEW FURNISHING OF FLOWER BEDS, BORDERS AND VASES.

I HAVE already sent you a good sample of the freshness and grandeur of this style, at once very new and ancient, in my note respecting the most effective use of single Hollyhocks in the enrichment and adornment of the Regent's Park. This style of using flowering plants for the furnishing of beds and borders was one of the first, as it is likely perhaps to be also the last, in decorative gardening. Among my first memories of practical gardening were the massing of Phloxes, Delphiniums, Snapdragon, Hollyhocks, Dahlias, Pentstemons, Verbenas, Calceolarias, &c., in tens, twenties, thirties or more on the terraces around Seone Palace. Annuals of various sorts were employed to separate the groups from each other, and add to the brilliancy as well as beauty of the colouring. This mode of using blocks of colour of differing heights and forms had most of the virtues and few of the faults of the more formal and glaring bedding-out system that followed. That system may be said to have died, so far as it is dead, through the glare and garishness of its colouring. At its height it was well and truly called the "scarlet and yellow fever," and these names did much to kill or improve it off the face of our flower beds and borders. Still, the foundation of most of our effective gardening stands sure and stable in our flower beds and borders. True the masses may be too big or garish or badly matched with other contiguous or impinging masses, but the mass in itself is a thing of power as well as of beauty in the enriching and ennobling of our landscape.

For example, one plant of bright scarlet Pink or golden Carnation, Hydrangea, Bamboo, Heliotrope, Phlox, Marguerite, Fuchsia, pyramidal Campanula, white fragrant Begonia is beautiful; but multiply it by ten, twenty, fifty, or a hundred and the beauty grows far beyond the mere numerical addition of numbers. Yes; and it grows fastest and to the highest landscape effect when each colour is used in sufficient quantity as well as of the proper mildness and intensity. The new furnishing, while clothing the glitter and glare of the bedding-out style and the coldness and stiffness of carpet bedding with chaster grace and fuller beauty, must beware of being dragged into

dreary monotony in the clothing of landscape through indiscriminate mixtures of all the colours thrown on the canvas or planted into beds or borders at random. The chief danger ahead in our new style of furnishing gardens, parks, and landscapes is not the paucity, but the excess of colour, which is all too frequently mixed down into weakness and mediocrity. In many of our arrangements one finds two or three arrangements at different heights. One huge mass of Hollyhocks at the Regent's Park had a ground clothing of *Nicotiana glauca*, *Crocus tinctoria*, and an edging of *Heliotrope*, *Paper-white* dwarf herbaceous Phloxes, and *Marguerites*, very rich, perhaps too much so, and too many plants and colours in one mass, for other large groups of single Hollyhocks fringed with a broad band of London Pride produced a more stately, unique, and telling effect.

On the other hand, an irregular piece of carpet bedding, or a shape near the divergence of two main walks, presented a maze of beauty almost as bewildering as pleasing. The ground was irregular, the size of the group irregular, the form informal or unequal, and the height of the plants, as will be seen when named, very varied and distinct. The groups were distinguished by vigour and prodigality of growth and of blossoming. Where the groups met they more or less overlapped and mingled. And no attempt seems to have been made to maintain sharp lines between the blocks of colour that distinguished the different plants. A mixture of alternate plants of white and blue *Lobelia* was profusely used, as were two separate blocks of two *Campanulas* as unlike as the dwarf *C. carpatia* and the towering *C. pyramidalis*; Chinese Pinks, red and yellow dwarf *Nasturtium*, mixed *Viola*, Iceland Poppies, the all-too-seldom-seen mixed *Verbena* (once grown by thousands in every garden); the beautiful variegated *Chlorophytum elatum variegatum*, springing from a skylike carpet of blue *Lobelia*; *Echeveria secunda glauca*; the golden-leaved *Moneywort*, creeping capriciously, leaving trails of gold behind, over *Stenocarpus* in various directions, &c. Beautiful as all these groups were in themselves, each was apparently enhanced through its proximity to its nearest neighbour, the finishing touches consisting of a few dwarf, very healthy green plants of *Araucaria excelsa*, and a liberal sky-line over and above all the group or masses named of *Bridal Wreath*, *Francoa ramosa*. The flowers stood up well above the flowers of the groups, and the gentle breeze swayed them over the surface of this tangled skein of beauty. The effect was so magical and fairy-like that I felt forced to write down my impressions to send all your readers to see it for themselves before the rapidly coming autumn mists or wrecks its beauty. D. T. F.

SEMPERVIVUM ARACHNOIDEUM.

With the culture recommended on page 172, this Cobweb Houseleek becomes very effective in its own quiet way. When established in congenial quarters and left alone it is also much admired, although the rosettes are necessarily smaller and the silvery "cobwebs" less noticeable. In the rock garden in dry and sunny crevices it looks very well, and in cracks and holes in the stones it can be made to add much to the interest of a rock garden. I can well recollect it on the stones forming the barrow-shaped rockeries in Mr. Wolley-Dod's garden at Malpas. The Houseleek was planted there at the suggestion of Mr. W. Robinson, and the effect is a good one where the stones are not too much covered with other vegetation. On a low wall in my garden I have a nice little mound of the Cobweb Houseleek some 12 inches or more in circumference. A few years ago a single rosette was planted in a chink in the lime with which the wall is pointed. To give it a good start a small patch of loam, cow manure and lime rubbish, about 2 inches across, mixed with water like mortar, was jammed into the chink and the rosette inserted. The *Sempervivum* has increased apace and now forms a shield-like

ground, extending over much more than the compost inserted for it. There are now upwards of 100 rosettes. As may be expected they are closely packed together and are consequently small. A few flowers are produced annually, but they are not much desired, for the rosette which blooms invariably dies, as is the rule with the Houseleeks. Among others which do well planted in a similar was is *S. Regina Amaliae*. *S. Laggeri* is also very fine on my roof garden. S. ARNOTT.

Carsiborn, by Dumfrils, N. B.

STOVE AND GREENHOUSE.

DIPLODENIA ATRO-PURPUREA.

THIS is one of the more recently introduced species, having been introduced by Messrs. Sander and Co. some six years ago. It has been a disappointing plant to a certain extent, not in its flowers, for these are most lovely, but so many amateurs and others have utterly failed to grow it. It does not seem to be due to any constitutional defect in the plant, for at St. Albans it is growing and blossoming with the greatest freedom in quite a cool, corridor-like house. It is quite possible that many failures may be traced to giving too much heat, there being a disposition among many growers when plants go wrong to give more heat with a view to setting things right. This is, I think, the case in many instances where this plant has failed, one or two such having come under my own notice. That it will grow and flower with only a moderate degree of heat is certain, and I have yet to see the plant that can be grown cool that is not the worse for the application of strong heat. This species and the somewhat similar habited *D. boliviensis* should look charming grown together, as they both might be, in a cool stove. During the summer the heat need not be excessive, but I would not like to trust either in a cool house in the winter. As is well known, the flowers of the latter species are pure white, excepting a golden yellow eye, while those of *D. atro-purpurea* are a most beautiful tint of the deepest maroon, glossy and shining. It should make a beautiful plant for growing up pillars or rafters in light, warm houses, and the flowers have a fine effect under artificial light. Not only do plants in the earlier stages flower freely, but the length of time they remain in flower is remarkable. Every short side shoot has its corymb of flowers that open successively all through the summer and early autumn, and the colour is not particularly plentiful among stove and greenhouse plants. T.

Æschynanthus speciosus.—This is very fine just now grown in a large basket in a warm Orchid house, the semi-pendent habit induced giving the plant an added charm. The flowers are very bright orange-scarlet, freely produced at the end of the shoots. The plant may be propagated in spring by cuttings, and these should be grown as strongly as possible in heat and moisture the first season. After the growth is finished for the year, keep the plants much drier and a little cooler to induce them to rest, this causing them to flower more freely the ensuing year. It is a native of Java, and was introduced to this country about 1845.

Bouvardia Humboldtii corymbiflora.—This frequently fails to flower satisfactorily and is inclined to run up too tall, but with proper treatment this may be avoided. I have lately seen a good batch in full flower in 4½-inch pots, the plants being from 1 foot to 18 inches high and carrying from ten to twelve good trusses of bloom. These were grown from cuttings put in in January. Being of a distinct habit of growth, this requires different treatment from the other *Bouvardias*, especially after they are placed into the pots they are to flower in. They may be grown with the other varieties until they have made a good start after they have been stopped for the last time. After this they should be placed out in the open

where they will be fully exposed to the sun. If watering is carefully attended to and a liberal supply of manure given, there will be little chance of failure. After the plants are well set with bloom they may be taken under glass to open, for though in good weather they will bloom freely in the open, the flowers are easily damaged by wet or wind, and a slight protection will ensure a good display of pure white bloom, which is always valued on account of its fragrance.—A.

The Stephanotis as a greenhouse climber.—A few years ago, when converting a stove into a greenhouse, I had occasion to leave a plant of *Stephanotis* in its old quarters on account of its being difficult to remove. The roots of the plant occupy a brick pit built under the front stage. A portion of the stage would have had to be taken down before lifting could have been done, so it was decided to allow the *Stephanotis* to remain and take its chance. Although so left I never expected the plant would do any more good, as it would be subjected to conditions which one would suppose would be inimical to the *Stephanotis*. However, quite contrary to expectation, it made the usual growth the following spring, and has continued to do so each year since, while it always blooms with the greatest freedom every summer. It has been in flower for the past three weeks, and will last quite another fortnight. The trusses and pips are quite as fine and well developed as if grown in the usual way, while they last longer in good condition when cut than when grown in a stove. I never remember hearing of the *Stephanotis* succeeding under cool treatment, and it would be interesting to learn whether any readers of *THE GARDEN* have grown it under similar conditions, and if it is found to be as free-flowering as the plant forming the subject of this note.—A. W.

Gloriosa superba.—Totally unlike any other occupant of our stoves, the brilliant flowers of this climbing liliaceous plant are sure to arrest attention from their peculiar shape and striking colour, a mixture of vivid scarlet and golden yellow. It forms a curiously-shaped tuber, large numbers of which are sent to this country when dormant, in which condition they may be purchased at a moderate rate. Potted early in the year they push up climbing stems that make their way upward by means of tendrils on the points of the leaves. The flowers, which are borne towards the ends of the shoots, appear from July till the autumn. This *Gloriosa* is well suited for growing as a rafter plant in a small or medium-sized structure, as the foliage obstructs but little light, and the blossoms, curious in every way, well repay close inspection, which would not be possible in a lofty structure. *Gloriosa superba* is a prominent feature in many tropical regions, and was introduced to this country over 200 years ago. Exposed to the brilliant sunshine of the tropics, the flowers of this *Gloriosa* are even more richly coloured than we see them here. The cultural requirements are not at all exacting, yet a few items need be carefully carried out. For the culture of *Gloriosas* reference may be made to the number of *THE GARDEN* for October 9 last year, where their entire treatment is exhaustively dealt with.—H. P.

Physianthus albens.—This is a pretty greenhouse climber that toward the latter part of the summer and in autumn flowers very freely. The slender twining stems are clothed with opposite cordate leaves of a peculiar whitish tint, which give to a plant a very distinct appearance. The flowers, which are borne several together in the axils of the leaves, are whitish, somewhat urn-shaped, with the spreading segments prettily crisped. This *Physianthus* is a native of Brazil, from whence it was introduced in 1830. Cuttings of the weaker half ripened shoots strike root readily if put into pots of sandy soil and kept close for a time, while the plant grows freely enough in ordinary potting compost. It is nearly related to the ever-popular *Stephanotis floribunda*, and also to the genus *Schubertia*: indeed, beside the name of *Physianthus albens*, it is also known as *Schubertia albens* and *Arauja cerici-*

fera. The nearly-related *Schubertia graveolens* or *grandiflora* has attained a good deal of popularity within the last few years, and is now very generally met with. It was at one time spoken of as a rival to the *Stephanotis*, but is never likely to reach the same amount of popularity that the *Stephanotis* has attained. This is to a great extent owing to the fact that the foliage of the *Schubertia* has a very unpleasant odour, while the flowers do not possess the whiteness of the *Stephanotis*.—H. P.

GARDEN FLORA.

PLATE 1187.

DOUBLE PRIMROSES.

(WITH A COLOURED PLATE.*)

THE coloured plate issued with the present number of *THE GARDEN* represents a portion of a collection of double Primroses, than which no fairer nor more interesting flowers adorn our gardens. Why then are they so rarely seen, and why so difficult to cultivate? It is probable that the second question answers the first. They are rarely seen because they are difficult to cultivate. By cultivation I do not mean a feeble existence with here and there a poor flower, but a plant of noble habit, with rich, succulent foliage, 9 inches or 10 inches in height, a wealth of perfectly-formed blooms peeping in clusters from between the leaves, and numbering in well-grown specimens from 80 to 120 exquisitely formed double blossoms, possessing colour of a depth and velvety richness rivalling the Rose, and of a size little less than the Carnation, but unrestricted like these by the usual laws of plant colour, for amongst them are found all shades of crimson, yellow, and blue, whilst rich browns, whites, and blended shades combine to form a plant-picture of great depth and richness. Though the varieties of double Primroses are not numerous, their colours are distinct and include a few variegations, though the majority are pure selfs, which lend themselves to decorative design of an especially alluring nature. Nothing can be more beautiful than a well-staged basket of double Primroses carefully arranged and nestling amidst their own foliage in fresh green Moss, nor can anything be more dainty than a well-made button-hole of the same flowers of various colours.

Their value as cut blooms has never been appreciated, although we are a commercial as well as a flower-loving people. As an instance of the blooming qualities of these plants and their value to the sellers of cut flowers, I may mention a small bed, 9 feet 6 inches by 4 feet, of double white Primroses grown here, containing fifty plants, much too crowded, but carrying at one time an average of eighty open blooms per plant—an aggregate of 4000—all even size, of about 1½ inches in diameter, and this at a time when white flowers were specially sought for and commanded a high price. Their decorative value in the garden when highly cultivated is great.

* DRAWN FOR *THE GARDEN* BY H. G. MOON FROM FLOWERS SENT BY P. H. MILES, M.D., OLD PARSONAGE, GRESFORD. LITHOGRAPHED AND PRINTED BY J. L. GOFART,

yet they require comparatively little protection, whilst the space allotted to them need not be large. If it is desired to obtain early flowers, a frame 6 feet by 4 feet can be placed over them, supported only at the corners, for Primroses require plenty of air and are very averse to codling. At the same time I advise screens as a protection against cutting winds, which materially injure the delicate varieties, and I have found nothing cheaper nor more satisfactory than some light material, such as Heather or Fern or Reed straw, sandwiched between two layers of wire netting.

As companions to choice double Primroses, double Polyanthuses are all that can be desired, and as they flower later than the Primroses their value is appreciable. I know of only four varieties, but it is difficult to find a more beautiful flower than Golden Pheasant, with its wealth of rich golden brown, perfectly double blossoms, of which you may see six to ten on each stem; whilst Golden Ball, a stronger variety, with larger foliage and pink and yellow double flowers, as a cut bloom is hard to beat. Then there is the tricolour Rex Theodore, a combination of rich crimson and yellow, with each petal deeply fringed pure white; and the charming semi-double Flake, or, as it is known in Ireland, Prince Silverwings, a silver laced Polyanthus of great merit, of which a proportion of the blooms is single, others duplex, others again quite double.

For those who have never seen double Primroses in perfection I would select Pompadour, a beautiful velvet crimson, perfectly double, as a type; next double white, double lilac, double mauve, double yellow, double rose (bright, though a shy bloomer, with immense blossoms), double sulphur, double cerise, in the order written, but each is charming and has its admirers. The most difficult of all to grow is Pompadour, yet I have had it here in continuous bloom since October, and to-day (May 6) I have cut 100 fine flowers without appreciably diminishing their number. To grow plants such as these infinite pains is taken, and special beds are devoted to them, it being impossible to grow such in a general border, but, although this may rather militate against their general cultivation, who would grudge space, time, or trouble to achieve such results?

In sending double Primrose flowers to a distance, they should be pulled twenty-four hours before sending, tied in small bunches, with or without leaves, and immersed in water half way up the stems; then packed in damp Moss tucked round each bunch of stems, they will arrive perfectly fresh after a long journey and improved in colour.

P. H. MILES.

Old Parsonage, Gresford.

Garden labels.—Labels, and the little failings attached to almost every form of them, are a perennial source of discomfort, and we seem as far away from the one which is to be universally satisfying as our predecessors have been for generations. The great difficulty is to find a suitable and not too conspicuous label for low-growing plants, which shall remain legible for a number of

years and stationary as long as necessary. For wall trees, or any plant growing on or near anything that will hold a nail or tack, nothing can be better than narrow strips of sheet lead with the names stamped deeply into them, and with a hole at each end to receive the nails. Such labels are still in use here that were stamped more than sixty years ago, and the letters, though small, are as well defined and clear-cut as ever they could have been, and will probably remain so for another century. For the ordinary wood labels for all kinds of outdoor plants, I advise those who have the opportunity to try seasoned wood of Abies Douglasi, made into rather long and stout labels, painted in the usual way with white lead and written on with a black lead pencil while the paint is wet. I find this wood very durable, and that it takes the writing well. Some that were made and written on four years ago are now as sound and good as ever, which is not a bad record for a wooden label, being long enough to allow most of our border perennials to remain undisturbed. To further preserve the bottom from rotting, it is an excellent plan to dip that portion of each label which is to enter the ground into linseed oil or Stockholm tar, and then plunge it into a pot of sand to remain till dry. Good wood treated thus will remain sound for a dozen years, and probably more.—J. C. TALLACK.

THE WEEK'S WORK.

FRUIT CULTURE.

WATERING FRUIT TREES.—In many gardens this is still a serious item of labour, involving frequently time that cannot well be spared. Yet if fruit trees now in bearing are at all suffering at the roots it is work that must be done, being not only beneficial to the fruit approaching maturity, but also to the trees themselves. Of the two it is more important in the latter instance, as any serious neglect for want of water now will involve another season's crop in danger. In our own case, as an example no doubt of many others by the frequent expressions one hears of the want of rain, we are being compelled to water Apples and Pears which have been planted for several years, and which should by this time be well established. Plums also under the same conditions will frequently show symptoms of distress, and when this is indicated no further delay should be permitted. Cherries against walls as well as in the open need more moisture at this season of the year than is often credited to them, and the same remark applies to Apricots. By leaving the trees now to chance with the daily expectancy of rain is to run a risk of injury to the fruit buds of another year through imperfect development, which ought by all possible means to be avoided. Heavy autumnal rains will sometimes cause late growths, which are not desirable, but of this there need not be any apprehension with the ground so dry as it is at the present moment. Another crop which at this juncture is an important one is that of the Peach and Nectarine. Possibly, however, these have received the first attention, and so have in a measure been rendered safe. If not so well attended to, do not let the trees go any longer without water if they give indications of being dry, otherwise the red spider may still be reckoned upon to do its destructive work. Our trees of the latest kinds and those which have been cleared of fruit have up to within the past week been syringed, but owing to a good water supply we do not fear this insect; hence now this work will be dropped. The trees themselves will indicate plainly what their needs are, and such should not be mistaken for early ripening. Late Peaches and Nectarines on west walls are much later than usual this year in our case, and as the trees are bearing heavy crops in several instances they have been assisted by another application of manure. The borders were mulched some time back with clean litter, hence the soil does not get so parched upon the surface. The advice given from time to

time in respect to mulching has now its full application, and those who took the hint in time will without doubt be appreciating the same to their full extent as labour-saving in no small degree. Under all fruit trees of choice fruit a surface dressing of clean litter is very desirable. As a *resumé*, when watering, do it thoroughly and well, forking the surface if needs be where the ground has been trodden upon in order to equalise the distribution of the water.

PEACHES AND NECTARINES.—INSECTS.—At this season in many gardens the earwigs are a great source of annoyance to these and other tender fruits. Their presence can easily be detected by the perforations of the skin, which at once affords means of access to bees, wasps and flies, as well as ants, and the fruits are quickly spoiled. If very badly infested, a small proportion of hot water may be poured along the wall below the foliage; this may catch many in the cracks or joints of the brickwork and at the surface too. Higher up amongst the branches the time-honoured remedy of Broad Bean stalks is very efficacious, and it will always pay to have a reserve of these or similar material for this particular purpose. By blowing them out daily into a pail with hot water their numbers may be considerably decreased. Failing this remedy, some screws of paper, if tucked in between the branches, will constitute a refuge, of which they will take advantage. The best plan to adopt with all fruits so attacked is to gather at once, and, if required, use them for stewing purposes, and so avoid any waste. For wasps and the like we have never found any trap to surpass that of three hand-lights and frames placed upon the top of each other, being raised from the ground by means of bricks, for providing an egress to which they are decoyed by partially eaten fruit and by any sweetened liquid. The only other provision to make is that of a small perforation of the glass at the apex of the hand-lights, save the topmost one. Bottles of liquid hung in the trees will catch large numbers, but this means is rather disposed to entice them where they are not wanted. The green aphid is still a little troublesome upon the points of some shoots, but the advice given is to stop it at once with either quassia extract or XI. All Insecticide. To give advice as regards the destruction of wasps' nests is, perhaps, scarcely needed, but it is possibly not generally known that there is a most efficacious remedy in McDougall's squibs. These are far better than any dangerous poison, as sulphide of potassium, the absence of which from any garden is much to be preferred. Where it is seen that there is a superabundance of growths still upon Peaches or Nectarines it will be advisable to thin it out now, so as to admit more light and air to encourage a thorough ripening of the wood. It is comparatively easy now to judge the requirements in this respect, besides which any wounds now made will have a fair time to heal over. All lateral growths should also be thinned out, even upon young trees, where possibly some such have been retained in order to make as much progress as possible towards filling the wall space. Growths now in process of development, especially laterals, will not have much chance of ripening. See that all the fruits upon late varieties are well exposed to the sunshine both as regards colour and flavour, tucking the leaves on one side rather than stripping them off, and if the walls be wired, by trussing the fruits forward upon the wires by means of labels, so that they do not press against the wall. As a rule it will be found better to gather late varieties rather earlier than others if the weather should change to wet within the next week or two. They can be ripened tolerably well in freely ventilated vinerias.

PLUMS.—These will if well established resist the drought better than most fruits, but do not allow the crop, if a heavy one, to hang too long, otherwise the trees must be taxed. We find it a capital plan to thin heavy crops, even of dessert kinds, and use them for cooking purposes, thus enabling the finer fruits to develop fully. Within

the next fortnight or three weeks the fruits of Coe's Golden Drop for keeping afterwards for late supplies should be taken off carefully, being stored in the fruit room quite thinly. It is a good plan to wrap each one in tissue paper and then let them lie at a good distance apart. Take note also of Iekworth Impératrice for the same purpose.

NOTES ON FRUIT TREES.—Notes of observation from time to time as regards different kinds of fruit are most serviceable. Not only does this apply to those trees under one's immediate care, but also to what may be seen under the charge of others. Take stock of any trees not so fertile as they should be, and consider what may be done in grafting or root-pruning, so as to be prepared in good time. Additions to the stock should be a yearly matter, for the obvious reason that to add steadily affords better chances of success if labour be at all scarce. Do not attempt to keep old or decrepit trees when young ones are so abundant and as cheap as one could wish them to be. Make a point of selecting all that may be required in good time, and mark them for early removal. In doing this do not be attracted so much by a strong or luxuriant growth as by a moderate one in which also good proportions exist.

HORTUS.

KITCHEN GARDEN.

AUTUMN CABBAGE.—The heat and drought have delayed planting, and when there has been sufficient rainfall to moisten the earth it will be well to make later plantings of Cabbage, for with a good breadth of this vegetable in the late autumn and early winter months, there will be less need to cut those kinds of vegetables that will keep. Any plants of early-sown autumn Cabbage, I mean that sown for the spring supply, may be planted rather closely, and in good land will make good cutting material in November, as it will not be necessary to have large heads. If the green crops of any kind have not made the desired progress it is now a good time to make up deficiencies, for, though too late to plant most of the Brassicas, it will be an easy matter to put in late breadths of Coleworts. These grow quickly and are useful. Such kinds as St. John's Day and Christmas Drumhead may be planted, as they will make fair growth by the late autumn, keeping solid and good well into February. For many years I have planted late Savoy for use at the time named, but I find the autumn Cabbage more useful in a private garden. Size is not needed and the quality is excellent. Of course, in planting these sorts there must be no delay, but the growth will be rapid as the earth is warm.

BROCCOLI.—Most of the plants are now making a fair growth. Owing to drought they needed rather more attention at the start, but by drawing rather deeper drills than usual water was more readily applied. If any plants are at all backward now they will well repay supplies of liquid manure, as the ground is comparatively dry, and with ample moisture the time lost will soon be made good. When the roots are moist, moulding up should not be overlooked. For the past year or two we have planted rather further apart than usual, and by so doing more soil can be secured for the moulding. This with the dwarf-growing plants is an advantage, as they suffer less in severe weather if there is scarcely a stalk exposed. I find it best to mould up as early as possible, as it prevents winds damaging large plants with heavy leafage. Late plantings of Model and Late Queen will need more time to develop before moulding, and in light soil these should not suffer for want of moisture, as they will be useful to fill in the space between the latest Broccoli and the early Cauliflowers. I note that some of the early varieties of Broccoli, such as Protecting and Early White, are badly attacked with fly and grub, and unless means are taken to check the progress of these pests the heads will be poor. With a greater rainfall the pest will not spread, but it will be advisable to dust over affected plants with soot and lime.

RUNNER BEANS.—The plants up to the early part of the month have borne grand crops when planted in trenches. The roots suffer less in hot, dry seasons, especially if they have a good root-run of rich material, should the soil be light or poor. Few plants will take greater supplies of moisture than the Runner, if it has a large top-growth, and many people allow the haulm to run 10 feet or more. With so much top rains cannot reach the roots readily, so that moisture must be given, or the flowers will drop and the crop be poor. Liquid manure given now will be of great benefit to the plants and cause them to make fresh growth. It will also be advantageous to top any kinds that are above the stakes, which will induce fresh breaks and later bloom. The climbing French Beans are splendid croppers; indeed, I think they will in time oust the true Runner, as the haulm takes less staking. The plants do well topped at 6 feet from the ground, and the produce is gathered so readily, the quality being excellent. Excelsior, Tender and True, and Veitch's Climbing are splendid types of this new class of Bean, and if the plants are well fed they produce an enormous quantity of pods. Late rows of Runners not staked, but kept stopped, will now be flowering freely. These must get liberal supplies of water should the weather be dry.

ONIONS.—If sowing has been delayed owing to the dry weather, advantage should be taken to sow at the first opportunity for early summer use, as these plants are always valuable in a small green state. Many sow the autumn crop rather thickly, but I do not think it is a good plan, as the seedlings get much weakened in the row. For drawing in a small state I would advise that a few rows be grown specially. These may be sown rather thickly and thinned out as required for use. The spring-sown plants should now all be cleared from their growing quarters, as, even when pulled and laid in rows, they suffer from the damp and grow again, which prevents their keeping. I mentioned in a previous note the importance of thoroughly drying, and there should be no difficulty in this way this season, the bulbs having ripened in dry weather. In storing, the small Onions, which are used for pickling, may be sorted and laid on boards in a cool place, and the small silver-skinned kind, if grown specially for that purpose, should be placed under cover if at all damp and spread out thinly, as it is well to have them as firm as possible before using; they are then of better colour and skin more evenly. The last-named is a good variety to sow now for use in the salad bowl in autumn.

GLOBE ARTICHOSES.—In light soil the plants have suffered from heat and drought, and, though they like warmth, moisture also should not be wanting. The plants will give a late supply of heads, if the old flower-stalks and a portion of the old leafage be cut away, and the plants given liquid manure or a copious supply of water after the soil has had a dressing of fish manure, guano, or other fertilisers. It will also be well to give the soil near the plants a good mulch of decayed manure, as this will conserve the moisture given and encourage new growth. For extra large heads late in the autumn it is advisable to thin them before they attain size, and when it is intended to make new plantation the best plants should be marked for the purpose, as there are spurious varieties of little value. Plants raised from seed will now need severe thinning out, but so far I have never had much success with seedlings, the heads being poor and prickly, and in many cases of little value except for a fine leafage. Now is a good time to pull out inferior kinds. The rows may be made good in the early spring by dividing. Of those that are good for stock and produce succulent heads, I prefer the large purple variety, but there are some good green kinds.

OTHER ARTICHOSES.—There is little work at this season among the Jerusalem variety, but what little is needed should be done. These plants are often left after planting till lifting, and placed in out-of-the-way corners, but they well

repay better culture. I find the tubers are finer and better shaped if less growths are allowed. This may be done by using the hoe freely and cutting away sucker growths. The white varieties appear to me to need more light and air than the old reddish tuber. The latter grows anywhere in ordinary soil, and the white round variety is worth growing, as it is much liked for its better shape and whiter flesh. The Chinese Artichoke, though not large, may be cooked in such a variety of ways that it should not be overlooked. It is better known as *Stachys tuberosa*, and, like the larger roots, well repays good culture. It will make poor progress if not given ample supplies of moisture, as it is a gross feeder and soon affected by drought. I find it advisable to mulch between the rows with spent manure to retain moisture given, and, as it makes a late growth, by giving food the tubers will be larger.

BEETROOT.—The season in many places has been bad for shallow-rooting crops, and the Turnip-rooted Beet, having but a small tap-root, has suffered from the heat and drought, which has affected the quality, so that no time should be lost in lifting the summer-grown crop and storing in a cool place. I would advise that the roots should be placed in damp soil in a north border, in preference to a dry shed, as they soon shrivel. Poor roots are not worth keeping, as they lack flavour. Later-sown roots will, with more rainfall, be more succulent and will now make rapid growth. I have sown the Globe varieties quite as late as this with fair results, as they soon bulb, and, the soil being warm with moisture, growth is rapid. Of course the roots are small, but they are very good and keep well. When sown late it will be well to give good land and, to secure the best results, sow thinly and keep the plants frequently hoed between. Beets are not nearly as tender as many people think. I have had the Turnip-rooted kind good all the winter in the open ground, merely covering it with long litter in severe weather.

WINTER CARROTS.—I have mentioned the importance of this crop in previous notes, and the ready way in which they may be grown, but our earlier sowings in July and August cannot be termed a success, as, with so little rain, the seeds failed to germinate freely. With moisture, growth now will be rapid, and other means may be taken, such as dusting over with soot in showery weather and giving a light dressing of some quick-acting fertiliser between the rows when damp. Fish manure and guano are both good for this root, and when well raked or hoed in, the offensive smell from the manure is not noticed. Up to this date thinning will have been delayed owing to drought, but there should be no further wait, and as these roots are drawn in a small state, severe thinning is not needed. In the northern part of the country I always sowed Carrots during the early part of September, in turf pits that had grown the early Potatoes or protected plants. Grown in this way there will be no lack of young roots from December to May, but avoid thick sowing and thin early. Air freely in fine weather and give moisture when needed. Seed sown under glass early in the year is so long forming roots that there is a great gain by sowing either in the open early in August or in frames, as advised, and such kinds as Early Nantes or French Forcing. S. M.

Anomatheca cruenta.—This pretty little bulbous plant, referred to on page 171, behaves differently from most of our bulbs, as it flowers in such a short time when raised from seed, which readily ripens, and if sown early in the season will flower in the summer or autumn of the same year. So easily can it be raised from seed that if grown for the decoration of the greenhouse, and no attention is paid to the old flower-stems, self-sown seedlings will often crop up on neighbouring pots. This *Anomatheca* is a native of the Cape of Good Hope, and like many other pretty bulbous plants from that region, it is not much known. The bulbs are a good deal like those of a *Freesia*, but smaller, while the sword-shaped leaves are

disposed in two rows. The flowers, which are produced on scapes from 6 inches to 1 foot high, are nearly an inch across, and of a bright carmine-red colour, the lower segments being blotched with rich velvety crimson. While very pretty out of doors on a warm border, it may also be grown in pots for greenhouse decoration, in which case from eight to ten bulbs in pots 5 inches in diameter form effective little clumps. Where larger masses are desired pans are more convenient than large pots, and the Anomatheca being a shallow rooting subject does not require any great depth of soil.—H. P.

ORCHIDS.

PALUMBINA CANDIDA.

THIS has been rather fancifully called the Flying Dove Orchid, and though not a large or particularly showy kind, is interesting and pretty. It has small pseudo-bulbs and leaves about 8 inches in length, and the flower-spikes each bear about half-a-dozen blossoms. These occur in the centre of the young growth, and the individual blossoms are about an inch or a little over across, creamy white with a yellow centre to the lip. It is not so much grown in this country as it deserves, but whether this is from lack of plants or want of interest, it is certain that if a demand existed for them plants would be forthcoming. Many growers err in allowing too much heat, the consequence being that the plants soon get overrun with insects, and instead of strong, vigorous growth and flower-spikes, the pseudo-bulbs and leaves get weak and thin in texture and less flowers appear on the spikes. Although it is comparatively easy to destroy insects, the plants are weakened at first and their marks are often left to disfigure the foliage and bulbs. Some of the best plants of this kind I have seen were growing up close to the roof of a house where the autumn-flowering *Odontoglossums*, such as *O. grande* and others, were happy on the stages and *O. citrosum* was thriving on the roof. Rather a dense shade was put on to allow of some greenhouse Ferns to be included. Probably these conditions were somewhat similar to those obtaining in their native habitat; at all events, the plants were quite satisfied with the treatment, as the healthy, vigorous growth and freedom of flowering testified.

This class of Orchid not only likes cool, shady treatment in summer, but during the winter it likes as much light and air moving about the bulbs and foliage as possible. Droughts and cold winds are wrong, but if the air can be kept moving by opening the top ventilators slightly and allowing a fair amount of air at the same level as the hot-water pipes, the plants will one and all be better for it. The atmosphere must also be kept moist, and thus the plants come away freely in spring and grow freely without any check. The roots like a fairly firm root-hold, and not too much of it, as they seem more at home in small pans or baskets where the room is limited than when placed in the middle of a large pot, where they never feel the rim. The peat should be of a very fibry character and kept apart by small pieces of finely broken crocks rather than large lumps of charcoal. A little chopped Sphagnum Moss is also a good addition, and about an inch of this mixture over good drainage is sufficient for medium-sized plants. A good deal of care is required in watering at the roots, for very little suffices except when the plants are most actively growing. While at rest the roots may be kept quite dry for a considerable time, provided the atmosphere is fairly moist. Light syringings are helpful in

summer by keeping insects in check and a suitable atmosphere about the plants. *P. candida* is a native of Guatemala, and though, from a strictly botanical point of view, the name should be *Oncidium candidum*, the above is the one by which it is far better known. It was discovered by the Horticultural Society's collector in 1810, and first flowered in this country a year or two later in Messrs. Loddiges' nursery.

Cypripedium Smithi.—This is one of the Lawrenceanum hybrids, its other parent being the beautiful *C. ciliolare*, both of which it resembles, though of course it partakes more largely of the former fine species. It is much more refined than *C. Gowerianum*, or indeed any other I have seen in this class, of a lovely tint in the upper sepal and showing *C. ciliolare* in the petals and pouch. It is a very fine hybrid, raised by Messrs. Sander and Co. at St. Albans.

Epidendrum cochleatum.—This is the name of the species coming from "C. C.," and not *E. prismatocarpum*, an entirely different species. *E. cochleatum* is one of the section called "aulizeum," and has an inverted shell-like lip. It is one of the very oldest of known species, having flowered in the Royal Gardens at Kew considerably over 100 years ago. It is an easily cultivated species, thriving well in a house devoted to Cattleyas and *Laelias*. The most ordinary treatment as to roots and watering suits it perfectly. It is a widely distributed plant over a great deal of Central America.

Oncidium pulvinatum (C. C.).—This is correct, and a very pretty, useful species it is, flowering with great freedom over a long season and lasting well in good condition. It may be grown with the greatest ease by anyone acquainted with Orchids. The plants may be cultivated in pots, with good drainage and a compost of two-thirds Sphagnum Moss to one of peat, plenty of hard material being introduced. During the growing season it requires plenty of water, and also while the strain of flowering is going on. In fact, a fair supply of moisture is required all the year round. It is a native of South America, introduced in 1838.

Odontoglossum purum.—It is seldom that this species is shown or seen in anything like presentable condition, but when really well grown the flower-spikes are long and many-flowered, the blossoms individually about 2½ inches across, and very pretty. The sepals and petals are brownish, edged and sometimes blotched with tawny yellow. It has a fiddle-shaped lip, like a small *O. Pescatorei* in shape, usually of some shade of purple. It is a native of Venezuela, and likes rather more warmth in winter than most *Odontoglossums*; otherwise the culture of this species does not materially differ from that of other kinds. It does best in medium-sized receptacles, and must be kept moist all the year round.

Odontoglossum tripudians.—This is one of the most useful in the genus, as it nearly always flowers when few others are at their best. The blossoms are not quite so showy as those of *O. triumphans*, but they come as near this species as any. In its best form they are about 2½ inches across, the sepals and petals golden yellow, almost entirely covered with a large chestnut-brown blotch, the lip white or yellow, blotched with more or less deeply coloured rosy blossoms. It does well in quite a cool house all the year round, and is quite at home with such species as *O. Pescatorei*—with which it is sometimes imported—and *O. crispum*, the treatment in other respects being similar. It comes from New Grenada, and was introduced to this country by Messrs. Hugh Low and Co.

Oncidium Batemanianum.—This is a very pretty *Oncidium*, and I have noted it in good condition in several collections of late. The blossoms occur chiefly at the ends of the spikes, these being about 3 feet in length. The individual flowers are bright yellow, with blotches in

the sepals and petals of a pretty brownish tint. The crest on the lip is complicated in structure, but very pretty, and the blossoms last well in good condition. It is an Orchid about which a good deal of difference of opinion exists among botanists, and it has several names. Being a native of Minas Geraes, in Brazil, an intermediate temperature suits it best, and the plants are best in medium-sized pots or baskets in a compost consisting of equal parts of peat and Moss. It is singularly inconstant in its time of growing and flowering.

Sobralia xantholeuca.—This and the fellow species, *S. leucoxantha*, are two of the most lovely of *Sobralias*, and, fleeting as they are, the plants are well worthy a place wherever room can be found for them. Both foliage and flowers are strikingly handsome, and the number of flowers successively produced makes up for the evanescent character of the individuals. Their culture is so extremely simple that anyone even unacquainted with Orchids may, if the requisite heat and moisture is at command, grow them with the greatest ease. Large old plants may be freely divided for stock purposes, and as long as the divided portions have a lead or two they are sure to live and do well. Allow fairly large pots and drain them well, giving as compost equal parts of peat, loam, and chopped Sphagnum or leaf-mould. The roots are very strong and fleshy, and will take hold of an exceptionally strong compost, but this, on the other hand, must not be heavy; it must be well lightened up by the addition of large rough lumps of charcoal or crocks. Growth commences in spring and is very rapid until the apex is reached and the flowers produced. All this time a very free supply of water is necessary, but this may be considerably reduced while the plants are at rest.

LELIA XANTHINA.

ALTHOUGH for size this *Laelia* cannot equal many others in the genus, it is an extremely pretty plant, the colour of the flowers being very distinct. The pseudo-bulbs are about 6 inches high, and each bears a single leaf, from the base of which the flower-scapes issue. The latter bear about half a dozen flowers when the plants are strong and well grown, but usually there are not more than three. They measure about 3 inches across their widest diameter, the sepals and petals being yellow, differing considerably in intensity—some quite a golden tint, others more of a buff-yellow. The lip is yellow in front, streaked with purple. The culture of *L. xantheria* is not always so successful as one might wish; it is rather a difficult species to establish, and only a week or two since I saw a fine batch in flower, but on examination not one of the plants had made any roots to speak of, though they had evidently been imported some considerable time. Where many fail is in allowing too much moisture at first. Before the roots have time to get out into the new material water is freely poured about the plants, and this injudicious watering will often mean the ruin of the few roots that appear. It is better by far to keep up a moist atmosphere, and, by gently spraying the plants in hot weather, endeavour to induce root action. Should flowers appear before the plants have made roots they ought not to be allowed to open; but if they are particularly wanted, let them be cut directly they are at their best. By these means the plants will have nothing to check them, and if the temperature is kept well up—for *L. xantheria* requires a full *Cattleya* temperature at least—roots should be produced in plenty, and the plants will soon establish themselves. It is not a particularly vigorous-rooting species at any time, and for this reason the compost need only be thin, about an inch of good peat and Moss sufficing for plants large enough for 4-inch or 5-inch pots. This species also does well as a basket plant if suspended not far from the roof-glass in a sunny position, using the same compost as for pots. Regarding its flowering season it is very incon-

stant, blooming sometimes upon the young wood in autumn, and sometimes in spring after resting in sheath. During the winter the roots must be kept well on the dry side; in fact, it is not a very thirsty species even when making its growth. It is a native of Southern Brazil, and probably not a very plentiful species in its habitat. It was introduced by Messrs. Backhouse in 1858.

HYBRID ORCHIDS AT ST. ALBANS.

In the hands of a very efficient grower the hybridising department at Messrs. Sander's nursery is making rapid strides. There are many thousands of seedlings in all stages of development and from all kinds of crosses, and those who are privileged to look through the houses cannot fail to find them interesting and instructive. The seed is sown on the compost of thriving young plants of ordinary kinds, principally *Cypripediums*, and very beautiful little specimens some of these are. The difference in plants so well treated as these are, and others in the half-starved condition sometimes seen, is very remarkable, such kinds as the somewhat erratic *C. Spicerianum* and others finishing up lovely growths with immense leaves. Thus the seedlings get a good start in a clean compost, and the pure air of the district, too, has doubtless a good deal to do with their thriving appearance. They grow rapidly, whether they are *Cattleyas*, *Cypripediums*, or what not, the same health, vigour, and cleanliness being observed in all. Little plants, potted only a few days, were already pushing the little white roots which steady them in position and ensure their well-doing. It is interesting to note the white appearance of the seedlings in the early stages, also the difference—early apparent—between seedling *Cattleyas* and *Cypripediums*; the way the tiny bulbs of the former seat themselves as it were on the top of the compost showing thus early their epiphytal habit, while those of the *Cypripediums* seem to try and hide themselves under the compost. This, too, before a single leaf has appeared in the very earliest stages. Then again, the *Cattleyas* from the first are quite green, while many of the *Cypripediums* are quite white, others green and white. A very fine spray which settles on the plants in the form of dew is frequently used, and greatly to the benefit of the plants. Handling as they do so many thousands of newly-imported plants, Messrs. Sander have the pick of a lot of good varieties as parents; thus the hybrids as they flower are mostly of great merit.

NOTES AND QUESTIONS.—ORCHIDS.

Cattleya gigas.—The season is getting over for this superb *Cattleya*, but I noticed some lovely varieties at St. Albans recently. The *Sanderiana* and *imperialis* varieties are especially fine and well coloured, and I think generally the plant has done well this season. Its cultural requirements have often been noted, and it is a species that should be grown by all.

Cattleya Mendeli.—This is usually one of the most constant of *Cattleyas* and seldom seen out of season, but I have noted it on two separate occasions flowering, not on an old bulb, but on the apex of the current year's growth after the manner of *C. Gaskelliana*. It is a pretty plant, and is usually easily distinguished from the rest of the labiata group by the white markings about the lip.

Epidendrum prismatocarpum.—This I have noted in flower during the week, and though the individual flowers are somewhat small they are very pretty and bright in their peculiar combination of green, dark purple and rose. They occur on erect spikes from the top of the pseudo-bulbs and last a long time in good condition. It is not a difficult plant to grow, thriving in an intermediate house treated similarly to a *Cattleya*.

Stenoglottis longifolia.—In one of the cool Orchid houses at St. Albans there is a splendid batch of this pretty terrestrial species, a species that is so easily grown and useful and so easily propagated, that one wonders why it is not much

more seen. The plants here are in 6-inch pots, and though all bloomed freely in spring, every young growth has now a fine flower-spike appearing. Many are fully expanded, and there is enough to carry on a fine display for a very long time. It is propagated by dividing the crowns, and grows freely in quite a cool house in a compost similar to that used for the terrestrial kinds generally. There is no need to elevate the plants above the rims and plenty of water is required.

FRUIT AND VEGETABLE CROPS.

WESTERN.

Witley Court, Stourport.—In this district the fruit crops, on the whole, are very satisfactory. Apples are an excellent crop, and the fruits of a nice even size and clean. It matters little whether bush trees or standards, the result is the same. As showing the result of more extended freedom of growth in Apple trees, I have a large quantity of half standards which for years had been kept spurred in, but from leaving the growths intact, merely thinning them out to prevent crowding, the trees this season are bearing splendidly. Pears on wall trees are a fair crop, but thin on trees growing in the open. The fruits, however, are very clean and good. Plums are good, and the crop on wall trees exceptionally so. The majority of these latter were in bloom at the time of the blizzard in March, and although only protected with a single net the set was enormous; consequently the fruits have had to be thinned very heavily. This operation is imperative both to gain size in fruit and also not to jeopardise the chances for next season. It matters little how you feed a heavily cropped tree; it is bound to feel the ill effects of overcropping the following season. Apparently, as long as the atmosphere is dry fruit blossom will withstand much colder weather than it is credited with. I quite expected to see the whole slatter off. Apricots are the best crop I have seen in this district for years, although they had to withstand many a cold blast. Cherries were and are splendid. It is many years since the farmers received such remunerative prices. Peaches and Nectarines are good; the trees healthy and clean. Amongst small fruits Black Currants are under the average. Strawberries, though quite a fortnight later, were quite satisfactory. Filberts, Cobs, and Walnuts are a good average crop.

All kinds of vegetables are good, the exception being Carrots; most of the seed failed to germinate. Early Peas were good, and from the later kinds I expect to gather satisfactory crops. Midseason varieties went off quickly through drought. Potatoes are clean and good without any sign of disease. On the whole the vegetable crops are quite up to the average.—A. YOUNG.

Knightshayes, Tiverton.—In this garden there is a very fair average crop of Plums, Apricots, Apples, Cherries, Gooseberries, Black and Red Currants. Pears, Peaches and Strawberries are not so good. There was plenty of flower on the Strawberries, but owing to so much dry weather the fruit did not set well. I have heard a good many complaints of Apples falling very badly in the orchards round about here.

Vegetables have turned out very well, although a little late. Beans of all kinds have done very well. Early Potatoes have been excellent both in crop and quality.—J. DICKENS.

Castle Hill, Devon.—Strawberries are a good crop and the fruit fine. Currants and Gooseberries are also very fine. Pears are a very heavy crop. Apples are very thin; there was plenty of blossom, but it did not set well. Plums are rather thin. Early Peaches were very fine, but late ones are a medium crop. Cherries set well, but a great many dropped off when stoning.—W. H. PEARSON.

Yate House, Chipping Sodbury.—Apples and Pears are much under average and very partial. The trees blossomed well and set

abundantly, but the fruit was cut off by the severe frosts and cold east winds we had in the middle of May. Plums are thin. Cherries a fair crop. Peaches and Nectarines above average, and required a lot of thinning. The Peach trees outside are covered with canvas during cold weather. Currants, Black, Red and White, are above average, fruit clean and large. Gooseberries above average and very large. Strawberries are good. Raspberries a fair crop. Filberts and Cob Nuts are fairly good.

Vegetables taken altogether are very good. Potatoes are very good and clean and free from disease. Peas have been abundant and good, but late Peas have suffered from the drought. Onions, Beet, Parsnips and Carrots are very good. Celery and all kinds of Brassicas are doing well.—W. T. MOSEBY.

Abberley Hall, Stourport.—The fruit crops in this district this season are a fairly good average all round. Apples are very good, much better than I have had them for several seasons. Gooseberries and Currants, both Black and Red, have been very good, also Strawberries and Raspberries. I do not think the Peaches and Nectarines outside look quite so well as last year, but still there is nothing to complain of. Cherries have been a wonderful crop this year, the best known in this district for some time. Nuts, especially Walnuts, seem to be very abundant.

Potatoes I do not think will be such a good crop as last year.—WILLIAM CONWAY.

Widcombe House, near Taunton.—The fruit trees had plenty of blossoms and began to set well, but the very cold nights and frost in May cut most of it off. Pears and Apples are half a crop and rather small, owing to the drought. Cherries are a fair crop. Plums very scarce. Peaches poor outdoor. Red and Black Currants are excellent in every way, also Gooseberries. Raspberries and Strawberries did well.

Potatoes are turning out well, tubers large and free from disease. It is a fair season for vegetables around this part. It is six miles from Taunton on a high hill 900 feet above the sea level. The soil is very sandy and light.—E. ELSON.

Shotover Gardens, Wheatley, Oxfordshire.—Strawberries and bush fruits of all descriptions are abundant. Apricots are an average crop; fruit large and fine in appearance. Apples much under average. Plums medium.—J. BROADFOOT.

Iwerne Minster, Blandford.—The fruit crops here are very good, wall fruit especially. Pears and Plums are plentiful. Apricots a fair crop. Apples are scarce. Small fruit abundant. Strawberries were excellent. Royal Sovereign is the favourite sort here both for pot culture and general and main crop. It deserves all the praise that is bestowed upon it.

Vegetables are very plentiful, which was more than expected, as during the early spring it was a great trouble to keep the young plants free from insects.—T. FOOKES.

Whiteway, Chudleigh, Devon.—Early Cherries are poor, but Morellos are bearing well. Plums are poor. Small fruits, including Strawberries, are good. Pears are not so good, the fruit being small. Apples are an average crop, while Peaches and Nectarines are both good. The spring frosts caused a good deal of damage to Plums and early Cherries, and the drought since prevented the swelling of Raspberries to their usual size.

Vegetables of all sorts are fairly good, with the exception of late Peas, which are suffering from the dry weather.—JOHN D. NANSCAWEN.

Trelissick, Truro.—Apples are a fair average crop of most sorts, but there is every appearance of their being small. Peaches and Nectarines are very good and the trees unusually free from blister and insect pests. Early Alfred I gathered out of doors on July 10. Pears are fairly good; some trees are carrying a heavy crop. Cherries and Figs are the worst for years. Plums are very poor except Victoria, which promises well. The extensive Plum orchards in this neighbourhood are carrying abnormally heavy crops.

Bush fruits are very good, especially Gooseberries. Apricots and Nuts never do any good here.—W. SANGWIN.

Kimbolton Castle Gardens, Hunts.—Strawberries were a good crop, but soon over owing to the drought. Raspberries were an average crop. Gooseberries were very plentiful, also Red and White Currants, but rather small. Peaches are a good crop. Apricots only a fair crop. Plums are much below the average, also Morello Cherries. Apples are a fair crop and very small, owing to the blight in the early spring. Pears are almost a failure. On the whole a very poor fruit year.

The first sowings of Peas were very good. I consider the best early Peas Exonian, Gradus and William the First, and for late crops I find No Plus Ultra yield the best. All other vegetables are very good this season.—J. HEWITT.

Toddington, Winchcombe, R.S.O.—Apples are rather over average and of fair quality. Plums over average; trees attacked with aphids. Pears under average and poor in quality; trees badly blighted. Peaches, Nectarines, and Apricots are under average. Strawberries are an average crop of good quality. Raspberries rather under average. Black and Red Currants average; quality good. Nuts and Walnuts under average.—T. CLARE.

Norton Manor, Radnor.—Stone fruits are very scarce. Apples and Pears under average. Morello Cherries very good. Strawberries have been very good. Gooseberries a heavy crop. Black and Red Currants very good. Raspberries good.

Vegetables are very good in quality with the exception of Carrots and Cauliflowers, which have been infested with grubs.—WILSON PALLISER.

Clyffe Hall, Wilts.—Of early and midseason Apples there is a good show of fruit, but the Codlin moth is playing sad havoc, and many are falling. Late Apples are scarce. Pears are also scarce. Plums and Damsons are good generally, except in very exposed positions. Peaches, Nectarines, and Figs are good this year. Strawberries have done well where they were watered and mulched. Raspberries are scarce. There was a good show of flower, but a fall off in setting. Cherries flowered freely and looked promising in the spring, but the late frost and keen east wind at the time of setting ruined all fruit prospects for this season. Gooseberries and Currants have been very heavy and plentiful. Nuts are showing well except Walnuts, which are scarce.—S. G. HILLIER.

Bicton, Devon.—All kinds of fruit promised exceptionally well early in the season, and the majority have and are cropping well. Strawberries were an exceedingly heavy crop in spite of the drought experienced here while the fruit was swelling, Royal Sovereign, Sir Joseph Paxton, President, Empress of India, and Leader being the best. The first-named was the first to ripen its fruit, but quite ten days later than last year. Raspberries (Superlative), Black, White, and Red Currants have been loaded. Plums are carrying excellent crops against walls and as standards in the open, and sweet Cherries have been very good against an east wall. Morellos on north aspect have heavy crops. Apples are clean, the majority of trees carrying good crops, Peasgood's Nonsuch, Duchess of Oldenburg, Lord Sutherland, Ecklinville, Golden Spire, Kerry Pippin, King of the Pippins, Margil, Cox's Orange Pippin, and Ribston Pippin being the best. Trees in the orchard have medium crops, the trees suffering just now badly from drought, a great many fruits dropping off. Apricots have done better than they have for the past three years. Peaches and Nectarines are a good crop on south walls, but very thin on an eastern aspect, where the majority of our trees are. For this I blame the very cold winds during the flowering period. They were one mass of flower and appeared to have set well, but the majority ceased to swell after about the size of a Pea,

eventually dropping off. Pears are a fairly even crop, far better than last year. Doyenné du Comice, Winter Nelis, Beurré Diez, B. Bose, B. d'Amanlis, B. Superfin, B. Easter, Pitmaston Duchess, and L. Bonne of Jersey are all heavily laden and free from cracking. Taken altogether I consider this a most excellent season for all kinds of fruit. J. MAYNE.

Blackmore Park, Worcester.—Apples are under average. Blenheim Orange, King of the Pippins, Worcester Pearmain, Hawthornden (New), Dumelow's Seedling, and Lord Sutherland are the best. Pears and Plums are under average, quite a failure in some gardens and orchards. Cherries are over average. Peaches and Nectarines fair, but Apricots are under average. Small fruits, including Strawberries, have been good.—A. AUSTIN.

Shobdon Court, Hereford.—In this neighbourhood the Apple and Pear crop is much below the usual average, yet one meets in orchard and garden a few trees carrying a good crop. In these gardens, Strawberries, Currants, and Gooseberries have been good and abundant, all stone fruits a failure. Of Apples bearing fairly well, mention may be made of King of the Pippins, Yellow Ingestre, Tom Putt and Forester: of Pears, Williams' Bon Chrétien, Beurré Rance and Bessimo d'Hiver. The cider Apples in orchards are a poor crop, the variety known as The Green Norman in some cases is loaded with fruit, but many of the orchards are without a crop at all, and the trees appear to be run down with old age and neglect.

All vegetables are showing the effects of the long and continued drought, very little rain having fallen during the last three months.—THOS. PLUMB.

Compton Bassett, Wilts.—Of Apples some varieties are excellent, while other varieties are very poor. Of Pears there is an average crop upon most trees; Louise Bonne, Marie Louise, and Jargonelle are bearing heavy crops. Peaches are excellent. Of Strawberries, Royal Sovereign, Keens' Seedling, Sir J. Paxton, and Latest of All are the best. Gooseberries, both dessert and cooking, are very good, while Currants and Raspberries are also good. Plums are under average, though some varieties have good crops. Apricots are good, Shipley being the best. Cherries are good, but the trees are covered with blight and want a lot of attention. Medlars and Quinces are under average. Walnuts and Filberts are average crops.—W. A. COOK.

Road Ashton, Trowbridge.—On the whole the fruit crops here are above the average both in point of quality and quantity, notwithstanding the unfavourable influences brought about mainly by frost, cold winds, or drought. Insects were never more persistent, nor were birds more dependent on garden fruits for their sustenance than during the past few weeks. Apples generally are a fair crop, some bearing heavily, others few, or none, the latter remark applying very eurusly to the late-flowering Court Pendu Plat. Those bearing full crops include New Hawthornden, Lane's Prince Albert, Ribston Pippin, Golden Noble, Cox's Orange Pippin, Cellini, Yellow Ingestre, Stirling Castle, Worcester Pearmain, Peasgood's Nonsuch, Adams' Pearmain, Lord Burghley, Mannington's Pearmain, Ecklinville, Beauty of Bath, Warner's King, and Hoary Morning. Pears are not so uniform as Apples, a great quantity having fallen off after they had swollen to a size usually considered safe. The freest fruiting trees are Williams' Bon Chrétien and Beurré Clairgeau. Others bearing average crops are Beurré d'Amanlis, Duchesse d'Angoulême, Beurré St. Louis, Dunmore, Seckel, Beurré Hardy, Doyenne Boussoch, Louise Bonne of Jersey, Soldat Laboureur, Althorpe Crasane, Brown Beurré, Marie Louise d'Uccle, and Doyenné d'Été. The cold, frosty winds occurring at the flowering and setting periods undoubtedly account for the very partial crops of Pears, and this failing is more conspicuous in some gardens than in others. Plums, too, vary very much.

Here, there is quite an average supply, but there are cases in the neighbourhood where thinness rather than plenty is predominant. Of Green-gages there is a heavy crop needing an early thinning, but Coo's Golden Drop, the most largely grown of all, because so useful in late summer, is not bearing so full a crop as usual. Neither are Kirk's and Jefferson's, two varieties which supply such excellent summer Plums. Pond's Seedling and Victoria have both needed severe thinning on walls, as also have Prince Englebert, Blue Imperatrice and Early Prolific. Washington as usual is thin, but the late Gages are more plentiful. Cherries, particularly Morellos, set thickly, but the persistent attacks of aphides as usual caused many to fall prematurely. Dessert sorts fared similarly, yet May Duke and Governor Wood carried full crops. Apricots generally are thin, some trees and sorts very much so; others, Kaisha in particular, having to be thinned, so thickly did it set. Moor Park has about half a crop. Figs did not suffer any harm in the winter, and are now giving promise of a very good autumn supply. Strawberries have been excellent, though in my case rather late. Royal Sovereign, Vicomtesse H. de Thury and President supply the earlier fruits, the first named, it is needless to say, predominate the most largely. Sir Joseph Paxton has given a fine crop of bright berries. James Veitch, Unzer Fritz, Elton Pine and Eleanor have not done so well. Latest of All is my mainstay, and has fruited marvellously, and the berries have been all that one could wish for in size. It does best with me as an annual; two and three year old plants bear no comparison, neither in weight nor quality with the yearling beds. Monarch, Leader, Gurton Park, Georges Lesuir and Dr. Hogg are on trial, but their crop does not justify an expression of opinion as to their merits. Raspberries are the best I have had for the past six years, Superlative yielding the heaviest crop and much the largest berries. Black and Red Currants have given good returns; generally there has been a complaint of the smallness of the berries and indifferent quality of the first-named. The reds have been much better. Gooseberries were extremely thin, but fine in berry. The March frosts destroyed the embryo fruits. With me they bore the best crop on trees occupying a north border. Damsons are thin, Medlars average, and Nuts a full crop.

Vegetables have been abundant and good, Peas in particular, although the early sowings were badly crippled in March. Runner Beans have grown well, but the absence of rain caused the early flowers to drop without setting, so that the crop is late. Dwarf Beans were much hampered by slugs, and Turnips equally so with the flea. I never saw such mischief done by these troublesome pests to early sowings as this year. Potatoes are ripening prematurely, and on poor ground the crop will be very indifferent. The early and second early varieties are yielding a heavy crop on good land, and late ones give promise of a fair crop, but this cannot long remain so without rain. The rainfall for the last six weeks is less than half an inch in this neighbourhood, and garden crops of all kinds are suffering from the effects of this and the attendant tropical summer weather.—W. STRUGNELL.

Cirencester House, Gloucester.—The fruit crops in some gardens are almost a failure, while not many yards distant a fair crop may be found. Strawberries were fine in every way in this garden. Apples are good. Pears scarce. Small fruit fair. Cherries good. Apricots, Peaches, and Nectarines fair. Plums good.

Vegetables have been excellent up to the present date, but are now suffering from want of rain. It is now a month since we had anything like a soaking of rain. Potatoes are good and no disease, but require rain to finish them off.—THOS. ARNOLD.

Tregothnan, Truro.—The fruit crop here is the best we have had for several years. Apples and Pears are rather thin, but all other fruits are about average. Peaches and Nectarines are excellent, both with regard to crop and health of

trees. Cherries (Morello) and Plums are good. Red, White, and Black Currants good average. Raspberries and Gooseberries a very heavy crop. Strawberries by far the best we have had for the past five seasons.

Vegetables are variable. Early Potatoes are very good both in quantity and quality, but late varieties have suffered from drought and will be small. Onions were badly infested with mildew early in the season; consequently the bulbs are small, but they are ripening nicely. Peas early and midseason gave good returns, and late varieties are doing well. Broad, French, and runner Beans are giving good crops. All the Brassica tribe with the exception of sprouts are doing badly, many of the plants going blind. All root crops are very promising.—WM. ANDREWS.

Castle Gardens, Sherborne.—Fruit crops in this neighbourhood are generally very poor. The prospects in the early spring were the best I ever remember. After the Pears had set a beautiful crop sharp frosts and cold east winds set in, which played sad havoc with them. Plums shared the same fate. Apples being a little later escaped, and of the following sorts we have good crops: Bismarek, Beauty of Kent, Blenheim Orange, Cox's Pomona, Easter Pippin, Ecklinville Seedling, Kerry Pippin, Lady Henniker, Lane's Prince Albert, Lord Sutfield, Lord Derby, Peasgood's Nonsuch, King of the Pippins, and Sturmer Pippin. Peaches and Nectarines are very thin; they bloomed too early and were badly cut. Of Apricots I had a nice sprinkling. Morello Cherries are a heavy crop; other sorts do not thrive here. Raspberries and Strawberries have been more plentiful than for many years. Bush fruits generally have been very good. Nuts are scarce.

Early Potatoes are very good, but small, and owing to long drought I fear the later ones will be no better in size. The vegetable season has been very good on the whole.

Stourton Court, Stourbridge.—All sorts of small fruit have been plentiful in this district, especially Strawberries, which have been a splendid crop. Plums and Damsons are almost a failure; the latter quite so. Pears are a good average crop, also Apples.

Early vegetables did very well with me, as they got a good start before the dry weather came.—T. SIMSON.

TREES AND SHRUBS.

A NEW FRUITING TREE—FEIJOA SELLOWIANA.

Among the woody plants which I introduced alive into Europe on my return from a journey to La Plata in 1890, I consider the subject of this note to be one of the most important and useful in horticulture. It is a true fruit tree. That its native country is South Brazil and Uruguay shows that it will thrive in Mediterranean provinces, Algeria and Tunis. The specimen I possess of it in my garden at Golfe-Juan produces both fruit and flowers; it is now 11 feet 6 inches in height and of equal breadth. In form it is bushy, but it can be got high in the stem, too. Feijoa Sellowiana was named by Berg after specimens obtained by Sellow in Southern Brazil, not far from the Uruguayan frontier. This is the region of the *Cocos australis*, which alone is sufficient indication of the climate suitable for the cultivation of the new arrival. The species Feijoa was dedicated by Berg to J. da Silva Feijo, Director of the Natural History Museum of St. Sebastian, in Brazil. This name was substituted for that of *Orthostemon*, which at first he invented for the *Myrtaca*, the subject of this note, but afterwards withdrew from it on finding it already applied to a species of *Gentiana* established by Robert Brown. The

change of name was noted by the author himself in his "Flore du Brasil." The description given of the plant by Berg was made from some dried specimens obtained from Sellow, who gathered the plants in the province of Rio Grande de Sol and, as it appears, in the neighbourhood of Montevideo, where the plant is

by Gaudichaud in 1833, and belonged to the Imperial Herbarium of Brazil, where the plant is numbered 1322. Another specimen which was given by the Herbarium of Berlin in 1861 was obtained from Sellow himself, and shows the flower open. But these precious examples have not sufficed to enable the artist who made

Feijoa Sellowiana.

known by the name of "Guayabo del pais." Gilbert also in his account of the plants of Montevideo mentions it. The herbarium of the museum contains some good dried specimens of buds and young fruit, brought from the province of Rio Grande, which were gathered

the drawing to give the exact forms of the petals, which are cucullate, not flat; and the description given by Berg is insufficient also, because it makes no mention of this peculiar form, nor of the colour of the corolla, which is a violet-red within and white outside. Another

species gathered by Sellow near the town of San Francisco de Paulo, in the same province, and named by Berg F. obovata, differs from Feijoa Sellowiana in its smaller stature, in its compressed branches and in its transparent and punctured leaves; it has not yet been introduced.

We are now, therefore, in possession of a new fruit tree in the Côte d'Azur, and the warm regions of the Mediterranean basin and even other countries of colonial France.—ED. ANDRÉ, in *Revue Horticole*.

SOCIETIES AND EXHIBITIONS.

THE NATIONAL DAHLIA SOCIETY.

SEPTEMBER 2 AND 3.

THE annual exhibition of this society was held at the Crystal Palace on the above dates, and may be said to have filled the whole length of the nave, in addition to which there were collections of Dahlias and other flowers at the sides, furnished by leading nursery firms, not for competition. The light was good, and all the types of the Dahlia were seen to the best advantage.

The large show and fancy varieties generally lacked refinement; it is one of the results of the changeable temperature in association with the drought. Still there were some very fine blooms staged. The Cactus varieties increase by leaps and bounds; new shapes and colours appear, and it is pleasant to record decided improvements in the habit of growth, which better fit the type for employment for decorative purposes in the garden. Such fine varieties as Messrs. J. Burrell and Co.'s Lucius and Mr. J. Stredwick's Magnificent seem to have almost reached the highest ideals in these types. Mr. T. W. Girdlestone's charming new varieties of the single Dahlia are so attractive, that they are certain to cause a revival of interest in this type, while the pompon varieties, once so tall and irregular in growth, are now dwarf, compact, singularly floriferous, and invaluable as garden plants.

The leading class for show Dahlias was for sixty distinct blooms, the fancy varieties being allowed to be shown with what is technically termed the show varieties proper. The first prize was awarded to Mr. John Walker, nurseryman, Thame, and his best flowers may be taken as representing some of the finest in cultivation. They were Chieftain, Duchess of York, extremely bright in colour; Majestic, Florence Tranter, a charming light variety; R. T. Rawlings, S. Mortimer, William Rawlings, J. C. Vaughan, Arthur Rawlings, J. T. West, Duke of Fife, rich scarlet; Mrs. Gladstone, a most constant and delicate light variety; Rev. J. Godday, William Powell, our best yellow self (this bloom was selected as the best in the entire show); Nubian, Shottesham Hero, a light ground flower, tipped with deep purple; John Walker, the finest white self; Golden Gem, Harry Keith, Dorothy, Perfection, Jas. Cocker, Harry Turner, Shirley Hibberd, James Stephens, Muriel Hobbs, a highly promising new variety of this year; Wm. Keith, Hercules, Mrs. Mortimer, and Mrs. Langtry. The second prize was awarded to Mr. C. Turner, Royal Nursery, Slough. Mr. S. Mortimer, Farnham, was third. Mr. C. Turner, who appeared to have put his strength into this class, was placed first with forty-eight varieties distinct, including R. T. Rawlings, Prince of Denmark, John Bennett, &c. Mr. J. Walker was second, repeating in this class the varieties he staged in the previous one. Messrs. Keynes, Williams and Co., Salisbury, were third, and Mr. S. Mortimer fourth.

In the two following classes there was an entire change of exhibitors. The best thirty-six varieties were staged by Mr. W. Treseder, Cardiff, who had good blooms of Dr. Keynes, one of the most distinct show Dahlias in cultivation. Mr. George Humphries, Langley, Chippenham, was third, and Messrs. Kimberley and Son, Stoke, Coventry,

fourth. With twenty-four varieties Mr. G. Humphries was first, Messrs. C. Kimberley and Son second, and Mr. M. V. Seale third. Quite another section of exhibitors showed twelve blooms of Dahlias in division C, and there was a very close competition. Mr. J. Stredwick, Silverhill, St. Leonards, came in first with good blooms. Mr. J. R. Tranter, Henley-on-Thames, was second; his best blooms were J. T. West, Florence Tranter, Rosamond, Mrs. Langtry, George Rawlings, Perfection, &c.; third, Mr. W. Baxter, Woking. Then came an open class for fancy Dahlias in which only striped or tipped flowers can be shown. All striped flowers are necessarily fancy varieties, but while a pale ground flower with a darker colour on the petal edges is termed a show Dahlia, any flower in which the darkest colour is at the base and the lighter colour at the tip of the petal is known as a fancy flower. Most of the striped flowers and all the tipped ones are very attractive, and though the difference in point of quality between the show and fancy varieties is not nearly so marked as it was a few years ago, the sections are still kept apart, though in all the foregoing classes they could be shown together. Mr. J. Walker was first with twelve fancies, though it was a near thing between him and Messrs. Keynes and Co. Mr. Walker had Rebecca, Mrs. Mortimer, S. Mortimer, Duchess of Albany, Buffalo Bill, Comte de Sceaux, Hercules, Professor Fawcett, Cherub, Mrs. Saunders, Dorothy and the Rev. J. B. M. Camm. Messrs. Keynes and Co. were second and Mr. G. Humphries was third. Next came the open classes for Cactus Dahlias, and about these the interest of many of the Dahlia growers centre. Shown in bunches of six blooms the brilliant Cactus varieties made an important display, and they were greatly admired. Messrs. J. Burrell and Co., Howe End Nurseries, Cambridge, were first with a really splendid collection, including some fine new varieties of their own raising. The varieties were Regulus, Miranda, Mary Service, Keynes' White, Arachne, Cinderella, Starfish, Island Queen, soft lilac, a charming tint; Lady Penzance, Fantasy, Britannia, Night, Charles Woodbridge, very brilliant; Harmony, Fusilier, Cycle, and Lucius, orange-salmon, very fine and distinct. Messrs. Keynes and Co. were a remarkably good second, and Messrs. J. Cheal and Sons, Crawley, a good third. In the class for twelve bunches, Mr. S. Mortimer was first, Mr. Seale was second, and Mr. G. Humphries third.

A new class was introduced to the schedule for twenty-four distinct blooms of Cactus Dahlias, shown on boards in the same way as the show Dahlias. This innovation appeared to find general acceptance, as it enables some to exhibit who cannot make up bunches of six blooms. Nine exhibitors competed, the first prize going to Messrs. J. Burrell and Co., two-thirds of whose blooms were highly promising seedlings of their own raising; Messrs. Keynes and Co. were second, and Messrs. J. Cheal and Sons third. Those were the most effective stands which had foliage shown with the blooms, and it would perhaps be well if this was made compulsory on the part of the exhibitors. Stands of twenty-four varieties of pompon Dahlias in bunches of ten blooms made another very attractive feature, and it was gratifying to see that the exhibitors preferred the small, compact, even flowers instead of those of larger size. The first prize went to Mr. Seale, though the stands shown by Messrs. J. Cheal and Sons and Mr. C. Turner, which were placed second and third, were so remarkably close in point of quality, that the judges had to resort to pointing in giving their awards. Messrs. J. Burrell and Co. had the best twelve bunches, with varieties almost entirely the same as those named, and Mr. George Humphries was second.

The single Dahlias also were represented by two fine collections of twenty-four bunches, ten blooms in a bunch, and it was a very near thing between Messrs. Cheal and Seale, the awards going in the order of their names.

The amateurs' classes for show and fancy Dahlias followed. The best twenty-four blooms

came from Mr. R. Burgin, St. Neots, Hunts, a working man, who produces fine flowers. His leading blooms were Gloire de Lyon, H. Keith, R. T. Rawlings, George Rawlings, J. T. West, Prince of Denmark, Frank Pearce, Maud Fellowes, Prince Bismarck, Queen of the Belgians, Vice President, Mrs. Langtry, A. Rawlings, Colonel, W. Powell, &c. Second, Mr. Thos. Antiss, Brill, also with some remarkably good flowers. Third, Mr. Thos. Hobbs, Bristol. With eighteen blooms, Mr. R. E. West, Salisbury, took the first prize, and Mr. W. Mist, Ightham, second, both staging very good flowers. The best twelve blooms came from Mr. S. Cooper, Chippenham. Mr. E. Jeffries, Langley Burrell, was a close second. Mr. C. F. Keep, Streatham, was first with six blooms. They consisted of Mrs. W. Slack, Victor, Duchess of York, R. T. Rawlings, Miss Cannell, and Lord Chelmsford. Mr. E. West, Jun., Henley-on-Thames, was second, and Mr. H. A. Needs, Horsell, Woking, third. Mr. Burgin had the best twelve fancy Dahlias, and it contained excellent blooms of Frank Pearce, Duchess of Albany, Lottie Eckford, Mrs. Saunders, Rev. J. B. M. Camm, Dazzler, and T. W. Girdlestone. Mr. S. Cooper was second, and Mr. T. Antiss third. Mr. R. E. West was first with six blooms, and Mr. E. Jeffries second.

Cactus Dahlias were numerous shown by amateurs. The best twelve bunches, six blooms in each, were staged by Mr. Robert Keeble, Wyford, Berks, who had in excellent character Harry Stredwick, Cycle, Mrs. A. Beck, Harmony, J. E. Frewer, Mary Service, Starfish, &c.; second, Mr. J. Hudson, The Gardens, Gunnersbury House, Acton, who was a close second, having Mary Service, Arachne, Fusilier, Starfish, Island Queen, Fantasy, Regulus, &c. Mr. W. Mist, Ightham, was third. With six varieties, three blooms of each, Mr. H. A. Needs, Horsell, Woking, came first; second, Mr. R. E. West; third, Mr. E. Mawley, Berkhamsted. Then followed a class for nine varieties, three trusses of each, Mr. H. A. Needs again taking the first prize; Mr. Keeble second, also with good bunches; and Mr. J. Hudson was third. With six bunches of pompon Dahlias, ten blooms in a bunch, Mr. Geo. Wyatt, Waldegrave Park, Twickenham, was first. Mr. J. Hudson was second. His best were Nerissa, Tommy Keith, and Orpheus; third, Mr. W. C. Pagram, Weybridge. With six varieties, six blooms of each, Mr. R. E. West was first, Mr. C. F. Wood second, and Mr. R. Burgin third. Single Dahlias were also well shown by amateurs. The best six varieties, six blooms of each, came from Mr. T. Girdlestone, who had refined blooms. Mr. J. Hudson was second, and Mr. W. Mist third. With six varieties, six blooms of each, Mr. E. Mawley was first.

Floral decorations in Dahlias were represented by epergnes, Mr. J. Hudson taking the first prize, in which yellow, white, and orange Dahlias were charmingly mingled with appropriate foliage. Mr. E. Mawley was second, and Mr. Pagram third. Mr. E. Mawley had the best vase of twelve Dahlia blooms, using Cactus Starfish on long stems with appropriate foliage. Mr. J. F. Hudson came second; he had Starfish and Keynes' White. Mr. R. Edwards, Sevenoaks, was third. Only one vase competed for the special prizes offered by Messrs. Dobbie and Co. for three vases of the white decorative Dahlia Miss Webster, that from Mr. R. Edwards, Sevenoaks, which was awarded the first prize.

Two classes were provided for amateurs who had never won a prize at a previous exhibition of the society, one for six show and fancy varieties, in which Mr. W. Middleton, Towcester, was first, and Mr. J. W. Jones, Woking, second. The same exhibitors were first and second with six varieties of Cactus Dahlias, three blooms of each. Then followed certain open classes; one was for a bouquet. Mr. W. Treseder, Cardiff, was first, and Mr. M. V. Seale second. Next came one of the most interesting and attractive classes in the schedule, namely, for eighteen varieties of fancy Dahlias, in which only striped, tipped, or edged flowers were admitted. Mr.

T. W. Girdlestone was placed first with a beautiful lot, almost entirely or quite of his own raising, and the names only are given now, as it is proposed to deal with them separately. The varieties were Tominy, Violet Forbes, Ganlem, Nan, Tommy Tucker, Bal Masque, Princess Petula, Creole, Splish, Ruy Blas, Aladdin, Louise, Suzette, Folly, Trilby, Jeannette, Jack Sheppard, and Phyllis. Never before probably was a better stand of single Dahlias staged for exhibition. Mr. M. Seale was second, also with some charming blooms, particularly Tommy Harper, Emmie, Paragon Improved, Folly, Dorothy Seale, Guelielma, Duchess of Albany, and Phyllis. Then came nine classes for six blooms of Dahlias of a particular colour or type. The best six dark came from Mr. J. Walker, who had the Rev. J. Godday. Mr. G. Humphries took the second, and Mr. S. Mortimer the third prize with Arthur Rawlings. Mr. R. E. West was first with six blooms of any light Dahlia, having Mrs. Gladstone. Mr. Tranter came second with the same, and Mr. J. Walker third with Mrs. Morgan. The best six blooms of a yellow Dahlia were very fine, John Hickling, shown by Mr. J. Walker. Mr. Mortimer was second and Mr. Seale third, both with R. T. Rawlings. The best red was James Stephen, from Mr. Mortimer; Mr. West was second, and Mr. Seale third, both with Duke of Fife. The best white was John Walker, from Mr. Mortimer; Mr. Walker was second with the same, and Mr. West third with the same. The only bloom of any other colour was Duchess of York, shown by Mr. Seale. The best tipped Dahlia was fancy Comedian, from Mr. J. Walker; Mr. Seale was second with Mrs. Saunders, and Messrs. Frewer and Co. third with Peacock. The best striped Dahlia was fancy Rebecca, from Mr. J. Walker; Mr. T. Anstiss was second with Emin Pasha, and Mr. Mortimer third with Duchess of Albany. The best edged Dahlia was Miss Cannell, also from Mr. Walker; Mr. S. Mortimer was second with Rosamond, and Mr. Seale third with J. T. West. Mr. E. E. Fellowes' silver cup for the best bloom in the show was awarded to Mr. John Walker, for a grand bloom of William Powell, yellow self. The two special prizes, presented by Mr. Thomas Hobbs, Bristol, for the best show and the best fancy Dahlias exhibited by amateurs, were both won by Mr. R. Burgin, the first with a fine bloom of Arthur Rawlings, and the second with Frank Pearce. Some notes on the new seedlings exhibited shall be given next week.

Some miscellaneous contributions helped the general display. Messrs. Carter, Page and Co., London Wall, had a representative collection of cut Dahlias of an imposing character; so had Mr. T. S. Ware, of Tottenham, who filled a very large table. Mr. J. R. Box, Croyton, had a bank of blooms of his fine strain of Begonias, and Messrs. Dobbie and Co., Orpington and Rotheay, a large and fine collection of many kinds of cut flowers.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 6.

THE show in the Drill Hall on Tuesday last was interesting, and flowers of various kinds were represented.

Orchid Committee.

A first-class certificate was awarded for—

PERISTERIA ELATA.—This well-known Orchid had never previously been certificated. Its ivory white flowers with the representation of a dove are too well known to need description here. The plant sent from Her Majesty The Queen's gardens, Frogmore, was a remarkable example of good culture. The plant carried eight spikes of flowers nearly 5 feet in length. The foliage also was correspondingly large and robust. A silver Flora medal was awarded also for culture.

Awards of merit were adjudged to the following:—

CATTLEYA ELIA (C. bicolor × C. Warscewiczii).—This is a distinct and pretty hybrid, the sepals

and petals being beautifully formed and fine in substance. The colour is a distinct rose, suffused with a shade of amber, the quaint elongated lip wholly deep crimson-purple except the margin, which is light rose and beautifully fringed. It is a most desirable variety, raised by the Messrs. J. Veitch and Sons, by whom it was exhibited, in the Langley Nurseries.

DENDROBIUM SANGUINEUM.—This is a distinct and lovely species, having growth 18 inches in length; the sepals and petals rich scarlet, shaded with purple and white at the base, each about 1½ inches in length; the lip rich purple in front, the side lobes white, slightly suffused with purple. This came from the collection of Sir T. Lawrence, Bart., Burford, Dorking.

Messrs. J. Veitch and Sons sent a large and choice group consisting principally of hybrid Cattleyas, the most prominent being *Laelio-Cattleya callistoglossa ignescens* (L. purpurata × C. Warscewiczii), the large, well-balanced sepals and petals delicate rose, veined with a darker shade of rose, the large lip rich velvety crimson except the throat, where the influence of C. Warscewiczii is discerned by the yellow side eyes and lines through the throat; *L. C. Nysa* (Warscewiczii × *crispa*), the sepals and petals pale rose, lip crimson-purple, margined with white, the side lobes white, shading to yellow, with some purple at the base; *L. C. Eudora* (C. Mendeli × L. purpurata), with extra large flowers. *Cattleya Euphrasia langleyensis* (superba × Warscewiczii).

—This is one of the highest coloured and most striking hybrids that have been raised, the sepals and petals deep rose-purple, the lip deep crimson-purple, with a darker shade in front of the disc of the throat, the interior of the side lobes white, shading to yellow at the base, the exterior rose. Fine forms of C. Loddigesi, C. Warscewiczii, and C. Leopoldi were also included. *Epidendrum radicante-Stamfordianum* has the intermediate characteristics of the species indicated in the name. *Disa Chio*, which was described in our last report, was also included. A finely flowered plant of *Dendrobium endocharis*, with its white and brown highly perfumed flowers, was very attractive. The most prominent among the hybrid *Cypripediums* were fine forms of C. Mylo, C. *canthium superbum*, and the rare and beautiful *Fairrieanum* hybrid C. H. Ballantine. *Cycnoches chlorochilon* was also well represented. A fine plant of *Renanthera matutina* and a pretty form of *Masdevallia Imogene* (Schlimi × Veitchii) was also included. A silver Flora medal was awarded.

Mr. E. G. Cohen, 4, Hall Road, St. John's Wood, sent *Laelio-Cattleya elegans* (Cohen's var.). This is a remarkably fine variety, the sepals pale greenish yellow, with a slight purple suffusion and some brown spottings; the petals deep rose, suffused with a darker shade; the lip very broad, rich crimson purple, shading to yellow on the side lobes. The plant bore a raceme of seven flowers. Sir F. G. Freaque, Bt., Warfleet House, Dartmouth, sent *Dendrobium Phalenopsis* (Warfleet variety); this is a pretty form. The sepals and petals pure white, the lip white, with numerous purple lines on the front lobe. The plant carried a raceme of five flowers. Mr. C. L. N. Ingram, Godalming, sent *Laelio-Cattleya splendens*, the sepals and petals pale rose, the front lobe of the lip rich velvety crimson. Mr. O. O. Wrigley, Bridge Hall, Bury, sent *Cypripedium* Mrs. F. L. Ames (C. tonsum × C. Fairrieanum), a pretty form in the way of C. *vexillarium*, but with greener and larger flowers. Messrs. Hugh Low and Co. sent *Cypripedium palananense*; this is an imported hybrid, resembling C. *Kimballiana*, and supposed to be a natural hybrid between C. *Dayanum* and C. *Rothschildianum*, the dorsal sepal pale green, lined with broad dark brown lines; the petals green, suffused with brown, and lined spotted with dark brown; the lip brown, shaded and marbled with pale green. Messrs. F. Sander and Co. had *Cypripedium* William Trelease (Rothschildianum × Parisii), the broad dorsal sepal pale green, lined with deep purple lines; the petals pale green, suffused with rose, spotted with dark brown spots; the lip purple,

shaded with green—it has the intermediate characters of both parents—and C. Mrs. Edgar Cohen (callosum × niveum); this is a pretty hybrid in way of C. *Tautzianum*, but with smaller flowers. A nice plant of *Dendrobium densiflorum Schrodera* and a light form of *Cattleya Warscewiczii* were also included.

Floral Committee.

A first-class certificate was awarded to

ACER NEGUNDO ELEGANS.—A handsome form, in which the strong silvery and creamy variegation is well supported by ample greenery, sufficient, indeed, to render it not only useful, but attractive over a long season. The plant is also vigorous and free in growth. From Messrs. Paul and Son, Chess-hunt.

Each of the following received an award of merit:—

DRACENA DUCHESS OF YORK.—Elegant and graceful, just the kind so well suited by its growth and general bearing for use as a table plant; the leaves are only three-quarters of an inch wide and a foot or more long, gracefully recurving to the pot and marked with cream and red along the leaf margins, the latter being the mature tint. From Messrs. James Veitch and Sons, Chelsea.

DAHLIA MRS. PINDLEY CAMPBELL.—A good Cactus variety, with a striking shade of vermilion-orange, a novel and distinct shade. From Messrs. Cheal and Sons, Crawley.

DAHLIA LORELY.—This is likewise a Cactus kind of a very distinct type, the outer florets being of a warm rosy cerise and the centre white and well defined. From Messrs. J. Cheal and Sons.

DAHLIA COLUMBINE.—A prettily formed single variety of a rose-peach and orange, a compact flower of medium size. From Mr. T. W. Girdlestone, Sunningdale, Berks.

DAHLIA PUCK.—Also a single kind, identical in size and form with the last, but of an orange-fawn shade and a crimson ring at base of florets. From Mr. T. W. Girdlestone, Sunningdale.

DAHLIA LADY ROGERS.—A pompon variety, nicely formed, very compact and of purest white. From Sir Robert Hargreave Rogers, Bexley, Kent (gardener, Mr. Leggatt).

DAHLIA MAGNIFICENT.—A very handsome Cactus kind, self coloured, and of a uniform buff-fawn tone throughout. From Mr. James Stredwick, Silver Hill Park, St. Leonards.

LOBELIA RIVOIREI.—One of the herbaceous kinds, with rather large flowers on long spikes, the blossoms of a very soft delicate pinkish hue. It is of the green-leaved section, as distinct from those with crimson leafage. From Sir Trevor Lawrence, Dorking (gardener, Mr. Bain).

HELENIUM AUTUMNALE SUPERBUM.—The variety here named is fully 6 feet high, with much-branched heads of blossoms, the latter very freely produced. The example exhibited was scarcely in normal condition, as indicated in parts of the stem and also some flowers; the latter are small, but abundant. From Sir Trevor Lawrence, Burford Lodge, Dorking (gardener, Mr. Bain).

From Crawley Messrs. J. Cheal and Sons brought a very fine collection of trees and shrubs in a cut state, that gave an excellent idea of the well-nigh endless variety of useful and beautiful things for the further ornamentation of the garden. Consequent on the great heat on Tuesday last it might naturally have been expected that such things would have presented a sorry appearance, yet the examples generally were in capital condition and well represented its kind. Doubtless some preparation had materially assisted to this very desirable end. Some of the most notable things were *Aralia spinosa*, *Ceanothus Gloire de Versailles*, *Veronica Purple Queen*, *Hedysarum multijugum* with purple pea-shaped flowers, *Coronilla Emerus*, a yellow-flowered species; *Diplopappus chrysophyllus*, a very distinct bush, with stems of a golden hue; a variety of *Acers*, among which was *A. Negundo aurea*, a rather good golden form; *Acacia neo-mexicana* with rose blossoms, the golden *Kerria*, elegant flowering branches of *Tamarix parviflora*, *Amorpha canescens* with its pretty violet-blue flowers

tipped with the protruding golden anthers, the richly coloured *Colutea crocea*, Japanese Wine-berry, several *Hypericums*, *Spiraea callosa*, *Quercus* and *Ulmus* in variety, making up a most interesting assortment of bright and useful subjects. Adjoining these things the Messrs. Cheal set up in their well-known form a really fine lot of Cactus, single, and pompon Dahlias in all the leading kinds. A few of the best Cactus noted were Lady Penzance, fine yellow; Fantasy, reddish amber; Gloriosa, scarlet-erimson; Harry Stredwick, maroon; Miss Webster, white; Night, blackish maroon; Mrs. Serase-Dickins, fine yellow, &c. Among the singles, *Alba perfecta*, Amos Perry, Duchess of Fife, The Bride, Lowfield Beauty (a lovely terra-cotta), Jeannette, May Sharpe (orange and buff) were all fine—a similar remark applying to an extensive assortment of pompons. The flowers throughout were of a high standard of excellence, and for the exceptionally dry season much above the average, thus reflecting not only good culture, but attracting attention to details. The whole of these extensive exhibits occupied an entire table, and well merited the silver-gilt Banksian awarded.

Mr. H. B. May, Dyson's Lane, Edmonton, set up a mixed group of Palms, Ferns, Carnations, and Bouvardias. *Salvia splendens grandiflora* is a most brilliant and effective subject at any time, and was staged in many well-grown examples. The Carnations were of the Tree section, and for the small pots in which the plants were grown carried nice heads of bloom, the varieties being the old and still very beautiful Miss Jolliffe, Mrs. Leopold de Rothschild—both pink kinds—Countess of Warwick, a fine claret-erimson colour, the petal good and the calyx perfect—this is doubtless the finest perpetual of this shade of colour, and a good tree habit; Primrose Bay, a good yellow, and the well-known Winter Cheer. *Bouvardia Humboldtii grandiflora*, in capital plants about 2 feet high and well flowered, *B. jasminoides*, B. Alfred Neuner, all nicely flowered, while the free-flowered *Fuchsia Ballet Girl* was bedecked with its handsome flowers at one end. Another rarely seen plant was shown in this group in *Swainsonia galegifolia alba*, an old pea-flowered plant of great beauty and usefulness. The elegant habit and pure white flowers are very pretty; it is a capital plant for bedding out in summer in pots. This interesting assortment was grouped on the floor, and received a silver Banksian medal. A group of *Cannas*, *Streptocarpus*, and *Ferns* was set up by Mr. Arthur Pentney, gardener to Mr. A. J. Howard, Worton Hall, Isleworth, the *Cannas* being all in a cut state and in great variety, the *Streptocarpus* being also well flowered (silver Banksian medal).

Hybrid Water Lilies were staged by the Messrs. James Veitch and Sons, Chelsea. They included some of the most beautiful of these lovely things at present in cultivation. Apart from the old white Water Lily (*Nymphaea alba*) were the newer *N. Laydekeri lilacea*, *N. L. fulgens*, a richly-coloured flower, quite an acquisition; *N. L. rosea*, *N. Marlissae carnea*, *N. M. Chromatella*, a useful and beautiful kind; *N. Ellisiana*, *N. odorata rosea*, *N. o. sulphurea*, *N. pygmaea helveola*, &c., a very beautiful and charming lot of these exquisite flowers. The whole of these, we once again endeavour to impress our readers, are as perfectly hardy as the old white Water Lily so well known among British rivers and streamlets. The same firm set up several baskets of *Hibiscus*, *H. totus albus*, *H. cœlestis*, very beautiful, and *H. monstrosus*, white with erimson base. Gladioli of the Childs section were also staged in considerable numbers, some of the best being Torchlight, Burlington, salmon self, and Nakomis, soft salmon-pink, and the pure white *G. gandavensis* White Lady, a flower of the purest white, though at present wanting in length of spike. Many beautiful annuals were also staged by the Chelsea firm, and among them Sweet Sultans in variety, *Dianthus Heddewigii*, Asters, Scabious, *Schizanthus* in variety, *Cosmos bipinnatus*, beautiful rose-lilac blossoms, and

many charming *Salpiglossis*, among these a beautiful chrome and orange-yellow, which is very fine (silver Banksian medal). Messrs. J. Hill and Sons, Lower Edmonton, had a fine group of greenhouse and stove Ferns in variety, including the new *Asplenium Hillii*, a most elegant plant with finely-cut leaves; *Pteris tricolor*, a well-marked Fern; *P. Victoria*, a silver variegated kind; *Cheilanthes elegans*, *C. hirta* Ellisiana, *Asplenium caudatum*, a capital piece with long, drooping, slightly arching fronds; *Lastrea lepida*, very elegant; *Pteris tremula* Smithii, a handsome example; *Adiantum Mariessi*, *A. fragrantissimum*, *A. rhodophyllum*, *Gymnogramma Mayi*, a good silver Fern; and *Davallia Tyermanni* being among the most worthy on this occasion (silver Flora medal). Mr. W. Rumsey, of Waltham Cross, sent a splendid lot of his new pink Rose Mrs. Rumsey, which has been so frequently seen in such excellent condition this year. The repeated exhibits mark it as a good perpetual, the blooms in question being of excellent size and suffering in no wise from the great heat of the past weeks (bronze Banksian medal). Mr. Sander, St. Albans, showed plants of the new *Acalyphus*, *A. Sanderæ*, and *A. Godseffiana*, both now well known; also a goodly batch of *Dracena Sanderæ* and fine flowering examples of *Hemanthus multiflorus* superbus with scarlet heads. Sir Trevor Lawrence, Dorking (gardener, Mr. Bain), staged a nice lot of spikes of the hybrid *Pentstemon* from seed sown on January 29 of the present year, the spikes in every way equal, and in some superior, to those produced from cuttings of last year; some spikes of *Lobelia Carmine Gem*, a lovely kind; the blue *Lobelia Gerardi*, which appears to come very near *L. syphilitica* in form; *L. Crimson Gem*, and a very fine seedling of an intense maroon-erimson. Another useful though variable plant was *Rudbeckia bicolor superba*, the colours varying from yellow and orange with erimson base to others almost wholly erimson. It should prove a good bedding plant by its freedom of flowering. Some spikes of *Belladonna Lilies* were sent by Mrs. Raven Hill, Woodside, Windsor Forest (gardener, Mr. John Wells), and from the same source a prettily marked *Acalypha* called *Novelty*—it is a dwarf kind marbled with cream and green—the plants flowering at about 6 inches above the pots.

Fruit Committee.

A first-class certificate was given to—
MELON BRITISH QUEEN.—This is the result of a cross between Hero of Locking and Royal Ascot. The fruits are oval in shape, skin pale yellow and very finely netted; flesh white, deep, and melting, and very fine flavour. From Mr. Owen Thomas, The Royal Gardens, Frogmore.
 Messrs. J. Veitch and Son, staged a very good collection of fruit, consisting of Apples, Pears, Plums, Peaches, Figs gathered, also shown in fruiting condition in pots, and long fruiting sprays of Red and Yellow Siberian and John Downie Crabs. The most noticeable among the dessert varieties were Devonshire Queen, remarkable for its deep mahogany colour and firm appearance, Lady Sudeley, Benoist, Duchess' Favourite, Kerry Pippin, Worcester Pearmain, and Yellow Ingestre. The cooking kinds were well represented, the best dishes being Stirling Castle, Warner's King, The Queen (a large handsome variety), Lord Sulfield, Potts' Seedling, Queen Caroline, and Dutch Codlin. Peaches, two good dishes of Sea Eagle and Princess of Wales. A fine dish of Dr. Jules Guyot Pear, also Clapp's Favourite, Beurré d'Amanlis, Fondante d'Automne, and Mme. Treve. Figs Negro Largo, White Marselles, and Bourjassotte Grise. Victoria and Denison's Superb Plums completed the exhibit, for which a silver Knightian medal was awarded. Messrs. Rivers, of Sawbridgeworth, again showed very fine fruits, orchard grown, of Peasgood's Nonsuch Apple. They also staged Plum trees in pots, carrying heavy crops of fruit. The chief varieties were Burbank, a large roundish Plum of good appearance, and which will be in great demand when better known, being a remarkably free cropper, and Archduke, a fine oval purple Plum,

good for dessert or kitchen. They also showed bunches of Gradiska and Buckland Sweetwater Grapes and a large white-berried variety named Centennial, with a very good flavour. A silver Knightian medal was awarded this collection. Forty dishes of Apples, both culinary and dessert, were staged by Messrs. Spooner and Sons, Hounslow Nurseries, Middlesex. A bronze Banksian medal was awarded. A cultural commendation was awarded to Mr. J. C. O'Hagan, River Holme, Hampton Court, for a remarkably fine dish of Exquisite Peach (River Holme variety), the fruits large, of an apricot-yellow colour, slightly marked with erimson where exposed to the sun; also a good dish of Rivers' Orange Nectarine (gardener, Mr. C. Last). A cultural commendation was awarded Mr. T. Robinson, Hollingbourne, Kent, for a box of Peaches. Cultural commendations were also given to Lord Foley, Ruxley Lodge, Esher (gardener, Mr. J. Miller), for Peach Princess of Wales; to Mr. H. Faure Walker for a very fine dish of Morello Cherries, this exhibitor also showing Tomatoes; to Earl of Galloway, Galloway House, Garliestown (gardener, J. Day), with a dish of Eury Grosse Mignonne Peach and Pitmaston Orange Nectarine, these being grown on a south wall without protection. Messrs. Laxton, of Bedford, showed fruiting sprays of the new perpetual Strawberry St. Joseph, also other varieties. Mr. W. Batchelor, Uxbridge, exhibited fruits of seedling alpine Strawberries, the flavour somewhat poor.

NATIONAL CHRYSANTHEMUM SOCIETY.

SEPTEMBER 6, 7, AND 8.

The exhibition under the auspices of the above society, and which opened on Tuesday last, was a welcome feature in the floral displays of the present season, and was clearly indicative of the trying period through which the different subjects have been passing.

CHRYSANTHEMUMS.

These were very poorly represented, there being only one competitor in the class for twelve bunches distinct, twelve blooms only to form a bunch, and this came from Mr. Eric F. Such, The Nurseries, Maidenhead, who was awarded first prize. Mr. Such was again the only competitor in the class for six bunches, six sprays to form a bunch, and these were only indifferently shown. The class in which the best quality was displayed was one in which twelve blooms of Mme. C. Desgrange or any one of its varieties were asked for. In this class there were two competitors, those from Mr. W. Perrin, gardener to Mr. C. W. Richardson, Sawbridgeworth, securing premier honours. These were handsome blooms of large size with long, broad, and drooping petals of good substance, and fairly even as a whole. Second prize was secured by Mr. Chas. Crook, gardener to the Dowager Lady Hindlip, Hadsor House, Droitwich. Mr. Such was again placed first in a class for twelve blooms of any early-flowering variety other than Mme. C. Desgrange and its sports, showing on this occasion twelve fairly good blooms of Lady Fitzwygram, which seemed somewhat lost in the big brown jars in which they were arranged. For the pompon class there were three entries, and Miss R. Debenham, St. Peter's, St. Albans, was a good first with nice blossoms of Alice Butcher (reddish orange), Mme. Gabus (very pretty), California (good), Mme. Jolivart, Piercy's Seedling, Mrs. Cullingford, Strathmeath (a doubtful pompon), and Precoicit and others. Mr. Such was placed second with blossoms of very poor quality. There was one competitor in the class for six blooms shown in a vase, and a very large obergne in the amateur division secured first prize for a lady exhibitor. The prettiest display in the Chrysanthemum competitive classes was made by Mr. Norman Davis, The Vineries, Framfield, near Uckfield, Sussex, who had a nice collection of cut flowers of Chrysanthemums of many types, and shown on a table 6 feet by 3 feet.

GLADIOLI.

Excellent exhibits of these flowers were staged. The best lot came from Messrs. J. Burrell and Co., Cambridge, and embraced many of the leading sorts and excellent seedlings. Specially good were Atlas, Althea, Grand Rouge (rich colour), Baroness Burdett Coutts (large chaste flowers), Fiametta (very fine), Comedy, Rosalind, Iona (rich velvety red colour), Casilda, Surine, Conquerant, Formosa, Lauretta (handsome spike, very chaste), Eunice, Dora Craven, Carnation, and Cameleon. Messrs. Harkness and Son, nurserymen, Bedale and Hitchin, showed a lesser number, their exhibit containing some twelve dozen spikes, of which the best were Enchantress, M. Chevreul, Mme. P. Palmer, Grand Rouge (a most constant sort), Formosa, and Mr. D. B. Crane (a chaste flower). This display secured second prize.

DAHLIAS.

SHOW AND FANCY.—These were well represented, although there have been occasions when the quality has been better. The principal class was one for forty-eight blooms, not less than thirty-six varieties, and in this there were five competitors. Leading honours were given to Mr. John Walker, High Street, Thame, who had a beautifully even and nicely finished lot of flowers. The most striking examples in his stands were Rev. J. Godday, Perfection, Daniel Cornish (very good), William Keith, Duke of Fife (very fine), Mrs. C. Noyes (a pretty light fawn), John Downie (very fine), Duchess of Albany (fine striped sort), T. J. Saltmarsh (yellow, neatly tipped chestnut), William Powell (splendid form, yellow), Warrior (one of the best scarlets), and Hercules (self). Second prize fell to Mr. Chas. Turner, Royal Nurseries, Slough, with smaller flowers, but a beautiful even lot of blossoms, neatly finished. There were five entries for thirty-six blooms, distinct. In this case also Mr. Walker secured premier honours, showing a very handsome lot of flowers, with neat finish. Second position was well merited by Mr. S. Mortimer, Farnham, Surrey, with good flowers, but lacking the finish identified with the leading stand. For twenty-four blooms, distinct, there were only two competitors, first prize being allocated to Mr. G. Humphries, Kington Langley, Chippenham, with a nice even and bright lot of flowers, though lacking the size seen in the other leading classes. Notable individual blooms were Daniel Cornish, Earl of Ravensworth (light lilac, very pretty), Mrs. Glascock, Vice-President, Arthur Rawlings, Dr. Keynes (very fine form and colour, buff), James Stephen (bright orange-scarlet), John Walker, James Vick and T. W. Girdlestone. To Mr. J. R. Tranter, Henley-on-Thames, fell second prize with a rougher and less even lot of flowers: Purple Prince, William Rawlings, James Cocker and John Standish, however, were good. Four stands were entered in the class for twelve blooms, distinct, Mr. Tranter standing out first with an even, though rather small, collection of blossoms. Mr. G. Humphries was a good second. In the amateurs' and gardeners' classes for twenty-four blooms, distinct, Mr. T. Anstiss, Brill, Bucks, was first with a good lot, having Vice-President, Harry Keith, Mrs. Morgan, Dr. Keynes, James Cocker, Imperial, Rev. J. B. M. Camm and John Walker (a good white self) in good condition. For eighteen blooms, distinct, there were three competitors, Mr. Anstiss again securing premier honours. Mr. R. Burgin, St. Neots, Hunts, received the second prize. There were four entries in the class for twelve blooms, distinct, Mr. S. Cooper, Langley Burrell, Chippenham, being first with a large and even stand of flowers, possessing good form and high colour. Mr. E. Jeffries, Langley Burrell, Chippenham, was a fairly good second, and in neither case in this class were the blossoms named. In the minor class for six blooms, distinct, Mr. C. F. Keep, 59, Sunny Hill Road, Streatham, was first, followed by Mr. S. Cooper, with neat flowers.

POMPONS.—These classes are always very interesting and pretty, the one for twenty-four bunches, distinct, having three competitors. In

this case Mr. Charles Turner was a good first with a charming display. The best were Adrienne (handsome), Bacchus, Hypatia (bright terra-cotta), Fabio, Tommy Keith, G. Brinckman, Mabel (lovely lilac), Douglas (one of the best deep maroon flowers), Isabel, Lady Blanche, Mars, Cecil, Marion and Iris. Mr. F. W. Seale, Sevenoaks, was a good second. In the twelve bunches Messrs. J. Burrell and Co. were a good first out of five entries, E. F. Jungker, Eurydice, Bacchus, Mary Kirk, Geo. Brinckman (very fine), Douglas, Phoebe, Isabel and Arthur West being a very handsome and even lot of flowers with a beautiful finish. Mr. G. Humphries was placed second, Captain Boyton and Ceres being noticeable in his stand for their good quality. For six bunches, open to amateurs and gardeners, there were four entries, Mr. James Hudson, Gunnersbury House, Acton, having a pretty lot of flowers. Mr. Geo. Wyatt, gardener to General Hilditch, Wandlegrave Park, Twickenham, was second. Taken as a whole the pompons were exceedingly fine and interesting.

CACTUS.—These were a grand lot, one or two stands being remarkable for their exquisite form and colour. The leading class was one for eighteen bunches, six blooms in each, distinct, in which Messrs. J. Burrell and Co. easily secured first prize. The varieties deserving special mention are Mrs. Peart, Starfish (grand), Casilda, Britannia, Keynes' White (very beautiful white), Mary (never seen better), Esmeralda (orange-scarlet seedling), Service, Arache, Lucine (fine form), Sirius, and Lady Penzance (very fine). Messrs. Keynes, Williams and Co., Salisbury, were the only other competitors, and were placed second. For twelve bunches, distinct, there was an imposing array of six exhibits, Mr. S. Mortimer leading with Starfish, Britannia, Mary, Service (grand colour), Fusilier, Keynes' White, Night, and Chas. Woodbridge. Second prize fell to Mr. H. Shoemith, The Nurseries, Woking, Surrey, with an interesting exhibit. There were four competitors in the sixes, Mr. James Hudson being a good first with pretty blossoms; Mr. G. Wyatt was second with a pleasing stand.

MISCELLANEOUS EXHIBITS.

These were varied in their character, and assisted very materially to add attractiveness to the show. A small gold medal deservedly went to Mr. H. J. Jones, Ryecroft Nursery, Lewisham, S.E., for a beautiful group of Chrysanthemums, Begonias, Caladiums, and fine-foliaged plants, with a fine background of lovely fresh green Bamboos. A new early Japanese Chrysanthemum named May Manser was much admired in this group, being a chaste white flower with a primrose centre, and which received a first-class certificate. A similar award was made to Messrs. Thos. Ware and Son for a very large and representative group of cut Dahlias. A circular group of Chrysanthemums exhibited by Mr. J. H. Witty, Nunhead Cemetery, was credited with a silver-gilt medal, and included many of the best known early sorts. Messrs. H. Cannell and Sons, Swanley, staged thirty bunches of early Chrysanthemums in twenty varieties, and secured a silver medal, a like distinction falling to Mr. F. W. Seale for a grand table of show, fancy, Cactus, and pompon Dahlias, a background being made of the smaller flowers with Asparagus foliage. A lovely lot of Tea and garden Roses came from Mr. John Mattock, New Headington, Oxford, who had beautiful bunches of the best and most popular sorts. This was a welcome addition to the show, and secured a silver-gilt medal. A small silver medal was awarded to Mr. W. Wells, Redhill, for a table of early Chrysanthemums, and these were in great variety. Mr. J. K. Chard, Stoke Newington, again exhibited specimens of table decorations, using Chrysanthemums, Montbretias, and a pleasing variety of foliage, and secured a large silver medal. Mr. John Green, Norfolk Nurseries, Dereham, made a grand display of Cactus and pompon Dahlias, remarkable for their colour and good form, securing a silver

medal. From Mr. F. G. Foster, Brockhampton Nurseries, Havant, came a large collection of Sweet Peas, which secured a small silver medal. Mr. J. Williams, Oxford Road, Ealing, secured a bronze medal for table decorations.

FLORAL COMMITTEE.

The committee met on the first day of the show, Mr. Thomas Bevan being in the chair. First-class certificates were awarded to:—

CHRYSANTHEMUM LOUIS LEMAIRE.—This is a beautiful bronzy red, on a yellow ground, sport from M. G. Grunerwald, and will be a welcome addition to sorts for hardy border culture. Like the parent variety, it is very free and dwarf. From Mr. W. Wells, Redhill.

CHRYSANTHEMUM MAY MANSER.—This is the best addition to the early Japanese sorts for pot culture introduced for a long time. The colour is a pretty ivory-white, with pale primrose centre, with long twisted and curling florets of good substance. From a natural break the flowers are now at their best. Height about 3½ feet to 4 feet. From Mr. H. J. Jones, Ryecroft Nursery, Lewisham.

A white sport from Blushing Bride pompon Chrysanthemum looked promising, and a request was made to see it again, and a bright crimson-scarlet border Carnation named Jeddah was commended. The latter came from Mr. J. Tigwell, Harrow View, Greenford.

Horticultural Exhibition at St. Petersburg—Mr. James H. Veitch has been appointed Commissioner for Great Britain and Ireland for the third International Exhibition of Horticulture organised by the Russian Imperial Horticultural Society on the occasion of the fortieth anniversary to be held at St. Petersburg in May, 1899. Schedules may be obtained from him on application at the Royal Exotic Nursery, Chelsea.

The weather in West Herts.—The past week proved remarkably warm for the time of year. On four days the temperature in shade rose above 80°, and on the hottest day, the 7th, reached 85°, which is the highest reading registered here in September during the thirteen years over which my weather records extend. On each of these hot days the highest temperature was registered at about 3 o'clock in the afternoon. The night preceding the 6th inst. was also exceptionally warm. On one day the temperature of the soil at 2 feet deep rose to 66° and at 1 foot deep to 71°, both of which readings are considerably higher than any hitherto recorded here in September. No rain fell during the week, and no rain water at all has come through either percolation gauge for five days. The record of sunshine has on several days been singularly good for an autumn month.—E. M., *Berkhamsted*.

Diseased Runner Beans (*Lynnhurst*).—Judging by the strange appearance of the small Runner Beans sent, we can but assume that some local cause has operated to render them so yellow and withered. It is altogether an unusual appearance. Closely examined, the small pods, both green and yellow, seem to be affected with a fungus or white mould, although very indistinct. It is late now to spray the crop, but it would rather earlier have been worth while to test the effects of a couple of sprayings of the Bordeaux mixture on them. If it be no fungus, then the only other inference is that there is something in the soil or in the water given that may be injurious. The incident is most uncommon. Do not save any seed from the plants or sow in the same ground next year. It seems too much to assume that you have had white frosts to injure the Beans, or that in your locality there were any foul gases generated to cause the young pods to turn yellow and wither up in this way.

Names of plants.—R. S.—Allspice tree (*Calycauthus floridus*).—A. T. Bowles.—Geutiana asclepiadea.

TREES AND SHRUBS.

NOTES ON SHRUBS IN FLOWER.

AMORPHA CANESCENS.—This curious little shrub—a native of the United States, where it is commonly known as the "Lead Plant"—is one of the few belonging to the Leguminosæ that flower as late as September. Although smaller and much less robust than the better-known *Amorpha fruticosa*, it is a handsomer plant and better worthy of a prominent place in the garden. It does not appear likely to ever grow more than 3 feet to 4 feet high in this country, whatever it may do in its native home, for it is killed back nearly or quite to the ground each winter, sending up a cluster of shoots, which bear their flower-spikes in a mass near the top during the autumn. The flowers are quite small, but very numerous, and clustered very thickly on the cylindrical spikes; the colour is a bright blue-purple, relieved by the yellow of the anthers. The foliage is also very pretty, each leaf consisting of numerous tiny leaflets pinnately arranged. Typically, the plants should have a greyish appearance, due to a dense covering of down on the leaves, but they vary considerably in this respect, some being comparatively smooth on the upper surface and of a darker green.

HYDRANGEA PANICULATA.—Certainly this is the most striking of the few hardy shrubs flowering at this late season, and this applies more especially to the variety *hortensis* (or *grandiflora*). There is a large bed containing both the variety and the type in the Arboretum at Kew, and they make, now they are in full flower, a very conspicuous and striking mass. In the variety *hortensis* (or *grandiflora*) nearly the whole of the flowers have become sterile—as so frequently happens with the members of this genus when brought under cultivation—and this change, although it makes the racemes somewhat heavy in appearance, at the same time renders them much more showy than the type, with its normal proportions of sterile and

perfect flowers. The racemes are immense pyramidal masses, the largest of which measure more than 1½ feet in length by 1 foot in width. The flowers last long in good condition; at first they are white, afterwards pinkish, and even when they have turned brown with age they are not without beauty. In order to produce racemes of the largest possible size, the plants are cut back in early spring, and after the young growths are a few inches long, from six to twelve (or more, according to the size of the shrub) of the stoutest are selected and the rest removed. The plants should be given a good mulching in the early summer and watered whenever necessary, the aim being to get the shoots as strong as possible. Towards flowering time they will need the support of a stake. After all, such masses of flower are something in the way of monstrosities, like the exhibition *Chrysanthemum*, and many may prefer the smaller, more elegant, but still striking racemes produced by unpruned, more naturally grown plants.

RHUS COTINUS.—In the pleasant and interesting grounds at Ribston Park, near York (famous for the Apple that originated there), there are now two fine bushes of this *Rhus* in their fullest beauty. There are larger specimens in the country, but I have seen none that have flowered more abundantly than these or produced a more striking display. The whole surface of the bushes, which are comparatively low and spreading, with a diameter, as near as I can recollect, of 12 feet or 15 feet, is covered with the feathery, pale rose or flesh-coloured inflorescences, almost completely hiding branch and leaf. This *Rhus*, although an inhabitant of our gardens for nearly 250 years, is still but little planted, yet it thrives in poor soil better than do many commoner things that are less beautiful. There is a variety with purplish leaves called *atropurpurea*, the colour extending also to the inflorescence, and there is also a green-leaved variety of pendulous growth. The species is known by several popular names, such as Venetian Sumach, Wig Plant, Smoke

Plant, Burning Bush, &c. It is a native of South and South-east Europe. The only other species in the same section of the genus is *Rhus cotinoides*. These two species are distinguished by their rounded, undivided leaves, the others having pinnate or trifoliate ones, as in *R. typhina* and *R. Toxicodendron*. *R. cotinoides* is very rare both in a wild and cultivated state, but it is one of the most beautiful of autumn-tinted shrubs. It is a native of a few isolated mountain summits in the Southern United States.

SYRINGA JAPONICA.—There is a section of the genus *Syringa* still scarcely known in gardens here which differs greatly from the Lilacs of the popular type. The three or four species that belong to it (and of them *S. japonica* is one) are distinguished by blooming later in the season and by their flowers being much smaller and bearing some resemblance to those of the Privets. A specimen of *S. japonica* is flowering now at Kew, and although small, it is sufficient to enable one to judge of the great beauty of the species when fully developed and flowering as it does in its native country. It is the most robust of all the Lilacs, making in Japan a tree over 30 feet high with a distinct trunk; in this country it seems inclined to retain a shrubby character. The flowers are a creamy white, and are borne in immense panicles 1 foot in length here, but described as twice as large on fully grown plants. They have a perfume somewhat like that of the Privet; this species and its allies do indeed form a connecting link between the Lilacs and the Privets, but it is an infinitely more striking plant than any of the Privets are. The leaves are of the Lilac shape and character, being broadly ovate, smooth and dark green on the upper surface, and firm in texture. It is a native of Northern Japan, and seems to have reached this country by way of the Arnold Arboretum, to which establishment it was introduced in 1876.

CLEMATIS FLAMMULA.—The prolonged heat and sunshine of the past two months appear to

have suited this Clematis, for it is flowering in great profusion, and the whole of the younger portions of the plants are wreathed with white blossom. Whilst very pretty both as regards leaf and flower, it is, I think, in the sweet, strong fragrance of the latter where lies its greatest charm. This fragrance so closely resembles that of the Hawthorn, that as one passes the plant, especially in the evening, he might imagine for the moment that May or early June were back again. This Clematis is an old plant in English gardens, having been cultivated here for more than 300 years. It is a native of Central and Southern Europe. Perhaps owing to its extended distribution in a wild state it varies a good deal both in regard to leaf and flower-panicle. For our climate none of the forms is better than the common one with finely-cut foliage and large panicles of small but numerous flowers. It can be easily increased by means of cuttings.

ARUNDINARIA AFRICOMA.—This Bamboo, so named by Mr. Freeman-Mitford two or three years ago, but known for a long time previously under the name of *Bambusa Fortunei aurea*, may now be added to the comparatively few hardy Bamboos that have flowered in this country. All the plants in the Bamboo garden at Kew are bearing flowers, and the same thing has been recorded at Batsford Park and elsewhere. It is apparently one of the species that flower simultaneously over large areas—possibly wherever it is grown—a very remarkable phenomenon considering how different must inevitably be the treatment and conditions the plants obtain in different places. The flowers at present are borne exclusively on last year's leafless stems; this season's growths are as vigorous as ever. It will be interesting to see if the species is one of those that die after flowering (as *Arundinaria Falconeri* does), or, like *Arundinaria Simoni*, flowers with no apparent loss of vigour. It is the latter result one must hope for, otherwise it would mean the loss to our gardens for some time of what is, perhaps, the brightest and most attractive of the dwarfed Bamboos. At this time of year especially the lively variegation of the leaves in green and yellow is most pleasing.

THE DWARF GORSE (*Ulex nanus*).—In the north of England the common Gorse (*Ulex europæus*) is almost the only one met with, and even as far south as the Surrey commons it almost entirely represents the genus. But in Devon and Cornwall it is *U. nanus* that predominates. On Exmoor especially it is extremely abundant. It differs from the common species not only in appearance, but more especially in flowering during autumn. From now till November this Gorse and the various species of Heath that grow there make the moors of the far south-west of England some of the most beautiful spots in Europe. Very frequently may be seen dwarf compact bushes of the Gorse, along with which has grown *Erica cinerea*, the intermingling of whose purple flowers with the golden ones of the *Ulex* makes a most charming combination. In gardens this Gorse is useful for its late flowering, especially on semi-wild banks and such like places. Although it is, as its name implies, a dwarfed plant than the common Gorse, it grows much the more quickly in a young state, forming very characteristic Foxbrush-like shoots during the first few seasons. It is better when planted in poor, rather dry ground, growing less rampantly and producing its golden flowers more freely.

CLEMATIS VITICELLA.—Although the old typical form of this species of Clematis does not make so showy a display as many of the garden

sorts do, it is scarcely inferior to any in real beauty. Its flowers, compared with those of the varieties and hybrids of the *patens* and *lanuginosa* sections are of course small—not a quarter the size of some of them—but they are exceedingly abundant and the plant itself is of greater elegance. The flowers vary in colour from blue and purple to white, and they hang in the greatest profusion the whole length of the growths. Commencing to open in July, they keep on without break till September. From the species and varieties of the *lanuginosa* and *patens* types, the *Viticella* group differs in the seed-vessels being smooth and devoid of the feathery awns that are so marked a feature of many of the Clematis. This plant may be trained up rough Oak branches or over arbours and pergolas where a covering is not needed to a greater height than about 10 feet.

B.

Rhododendron anthopogon.—The reference to this Himalayan *Rhododendron* in the interesting article accompanying the plate of *R. campylocarpum* in THE GARDEN of September 3 reminds me that I saw it in bloom in the Edinburgh Botanic Garden in April of this year. Although, as your contributor remarks, it is not a very striking or ornamental plant, it is an interesting one, and I should like to know how far it is hardy in the north-east of Scotland. I have not grown it here, but should not be afraid to try it had I not been able to grow other dwarf species of more beauty in my rock garden.—S. ARNOTT, *Carsethorn, by Dumfriess, N.B.*

Rhododendron ciliatum.—Perhaps I may be permitted to put in a plea on behalf of this dwarf *Rhododendron*, of which "W. J. B." speaks so highly on page 183. It is a charming species, and one of the prettiest ornaments of the rock garden during its season of bloom. In this district I have occasionally seen it suffer considerably in hard winters, but this may be avoided by following the advice given by your contributor in the article in which *R. ciliatum* is mentioned. In one rock garden with which I am acquainted it has for years formed a feature on a sheltered bank among other shrubs and alpine flowers. Nothing could well be finer than its blooms in the season. It is, I believe, one of the parents of *R. Wilsoni* as well as of those mentioned by your correspondent.—S. ARNOTT, *Carsethorn, by Dumfriess, N.B.*

St. Dabeoc's Heath (*Menziesia polifolia*).—In well-established clumps this is very pleasing, and the white variety is one of the prettiest hardy flowers we have. In gardens of large dimensions and where the soil is naturally favourable this Heath might be established in colonies. It is one of those things that will remain for an indefinite period in good condition without change of soil, and for this reason is better adapted for naturalising than many things of taller growth. What it likes is an open position, where it can get plenty of sun and abundance of pure air, and then if the rooting medium is right it will increase rapidly. I have set out quite small bits from pots, and in two years they made specimens 18 inches or more across, carrying hundreds of blooms. This Heath will grow in either loam or peat if the former is well drained and the latter is not too sandy and poor, and in any case it must not be intimately associated with rank-growing things that will deprive it of a full measure of light and air. It is easily increased by layering the woody shoots in spring, covering them with 2 inches of good soil.—J. C., *Blyth*.

Hypericums.—When the summer is on the wane the beautiful golden blossoms of some of the *Hypericums* are among the showiest of shrubby plants. The colour, too, is now but little represented among flowering shrubs, though in the case of herbaceous subjects the different shades of yellow are very plentiful. Among the best of the *Hypericums* are the Japanese *H. patulum*, and the hybrid between that species and the common

Rose of Sharon (*H. calycinum*). This hybrid form was raised by M. Moser, of Versailles, and under the name of *H. Moserianum* quickly became a great favourite in this country. This *Hypericum* may be planted in a bed by itself, in which position it will produce a great wealth of its comparatively large beautiful golden blossoms, or it may with equal advantage be planted as an edging to larger and bolder shrubs. Where some of the taller species of *Hypericum*, such as *H. oblongifolium*, are hardy, an effective bed for late summer and early autumn may have a centre of *H. oblongifolium* and an edging of *H. Moserianum*. Apart from the beauty of its golden blossoms, the common *H. calycinum* will flourish under trees better than most shrubs, which is indeed a great point in its favour.—T.

STOVE AND GREENHOUSE.

FREESIA REFRACTA ALBA.

Few sweetly-scented flowers are more useful or beautiful than this, and the bulbs in almost every case that has come under my notice this season have been larger and finer than usual. The largest bulbs do not always give the best results; indeed, I have had far finer flowers from small home-grown bulbs than from some of the finest imported ones, but as a rule if the bulbs are large and heavy for their size good flowers will be forthcoming. *Freessias* should be potted as soon as received in a light sandy compost and stood outside in some description of plant frame or protection, the pots being covered with about 2 inches of cocoa-nut fibre. Coal ashes or sawdust may be used, but the ashes are not always suitable, and I have on several occasions seen the tops of the young growths blackened when this material is used. This applies not only to *Freessias*, but to other bulbs grown for decoration. The growths start in a week or two after being placed in the ashes or fibre, and before the stems have time to get drawn they should be taken out and gradually inured to the light. A good plan is to place an inverted flower-pot on each potful of bulbs for a day, the next taking it off except for an hour or two, and as soon as possible placing the plants in the full light of a greenhouse or frame. The cooler the plants are grown, the closer to the light and the more air allowed the better. The growths will then be stouter and the flowers of more substance. All through the season of growth and until the flowers are fully open, plenty of water is necessary; the only time when it is dangerous is before the roots have obtained a good hold on the new soil. Occasional waterings with weak liquid manure are helpful. While the flowers are open the plants are best in a cool, shady house where there is no need of very free ventilation. A fairly dry atmosphere must be maintained of course, but too harsh conditions do more harm than good. The plants are extremely useful for indoor decoration and the scent is very pleasant, being quite distinct from that of most bulbous flowers and very like that of *Boronia megastigma*. After the flowers are over the water supply must be gradually withheld, but one of the most erroneous ideas is that as soon as they have done flowering they must be half roasted and water entirely withheld. The foliage begins to turn yellow naturally when the bulb is fully grown, and this is the time for withholding water. They are then doubtless the better for a thorough ripening, but if dried too early, small and weak bulbs will result. GROWER.

Fuchsia Ballet Girl.—It would be difficult, if not indeed impossible, to name any double

Fuchsia with greater freedom of flowering than this, the small bushes of a foot high being so loaded with the heavy double flowers as to cause the branches to droop to the pots, even though suspended to a central support. The flowers, too, are large, the very double and pure white corolla rendering it conspicuous against the bright reddish scarlet of the sepals.—E. J.

Swainsonia galegifolia alba.—Though a rather old greenhouse plant that was in favour many years ago, and still worthy of extended culture, this is very rarely seen at the present time. Recently, however, Mr. H. B. May had a nice lot of plants in bloom at the Drill Hall, the pure white Pea-shaped flowers showing to advantage amid the pretty and elegant foliage of the plant. The plant is of very easy culture, and answers well to the same treatment as *Coronilla*, *Genista*, and such things. It is an Australian plant belonging to Leguminosæ, and about as hardy as the two genera herein mentioned.

Carnation Countess of Warwick.—Many Carnations of the Tree or perpetual section have from time to time been distributed as good crimsions, thoroughly perpetual in habit, and so on, but most of them have failed to come up to their recommendations. The above kind, however, is not only of the right colour, it is also a good flower, good in form, and free from any splitting of the calyx, while its habit of growth promises well for its true perpetual character generally. The colour for a crimson is very bright, a elaret or wine shade lighting up the usually more sombre crimson hue; in short, it is the finest of this shade I have yet seen.

The Stephanotis as a greenhouse climber.—In reply to "A. W.," I once had a fine plant in a cool conservatory. The temperature in the house, which was large and had insufficient piping, frequently fell to freezing-point during very hard weather, and upon one or two occasions below it. Yet the plant, which was in a large pot and trained to the wall and roof, flowered abundantly. A companion plant to it was an unusually large *Hoya carnea*, which covered a large area and often had over 200 trusses open at the same time. This plant, by-the-by, was in a box only 18 inches by 12 inches and 6 inches deep. It was simply a mat of roots, all the soil having been forced out. Beyond copious supplies of water it had no special attention, and I am inclined to think that many Hoyas fail to flower through over-rich soil. To my knowledge the plant had not been rebaxed for twelve years.—GEO. PARISH.

Streptosolen Jamesoni.—Among the various subjects planted out in the beds in Hyde Park are some good-sized bushes of this *Streptosolen*, which have been for some time, and still are, flowering very freely. The flowers when first expanded are yellow, but they deepen in tint till finally they become of a bright cinnabar-red hue. This shade of colour, being very distinct from that of most other subjects in bloom, serves to at once direct attention to the *Streptosolen*. This latter generic name is that under which it was first distributed, and by which it is still generally known, but botanists tell us it is a *Browallia*, of which there are several forms in cultivation, but in nearly every case their flowers are of some shade of blue. *Streptosolen Jamesoni* thrives under much the same treatment as a *Fuchsia*, and cuttings of the young shoots strike root in the spring readily enough. For planting out, it is a very good plan to train the plants up with a leading shoot, as then the side branches are pushed out freely and dispose themselves in an informal manner around the main stem, the result being a very pleasing specimen. It grows freely enough in ordinary potting compost and needs little attention. Sometimes aphides make their appearance, but they are easily checked and do not give so much trouble as red spider, which under glass is apt to effect a lodgment on the foliage.—T.

Evolution of the Streptocarpus.—Since hybrid *Streptocarpace*s were first seriously taken

in hand about eleven years ago at Kew by Mr. Watson, many beautiful forms have been raised, showing great diversity and richness in colouring. Beyond increase in size, very little alteration, however, has hitherto been made in the actual shape or construction of the flowers, which, as everyone knows, are irregular in shape, drooping in habit, and with only two stamens, as a rule, fully developed and capable of discharging pollen. Now, however, a distinct break away from these characteristic lines has been effected by Mr. Pentney, gardener to Mrs. Howard, Worton Hall, Isleworth. By careful selection and hybridisation, Mr. Pentney has succeeded in raising a few plants which have regular flowers, the five lobes being symmetrically star-shaped, standing erect, or almost erect, on the stalk, and with five fully developed stamens. To growers of these lovely *Geneserads* this alteration of the floral characters will doubtless signify the beginning of a new race of *Streptocarpace*s, and a few years hence we shall probably see as great a change effected in this genus as has already taken place in the *Gloxinia*. In the latter genus, as probably all gardeners are aware, the erect and gorgeous trusses of symmetrical flowers as we know them to-day have been evolved or developed by cultural skill from a plant that had irregular and drooping flowers. If such marvellous results have been accomplished in the *Gloxinia*, it is at least reasonable to assume that the same can be done with the *Streptocarpus*.—JOHN WEATHERS, *Isleworth*.

ORCHIDS.

LELIA DAYANA.

FLOWERS of this pretty Orchid come from several correspondents, but few varieties of it at present in general cultivation can compare with the earlier forms. The plant is difficult to keep in thorough health, these small-growing kinds being so liable to injury by fluctuations of temperature and other checks to growth. There can be no doubt that many growers still believe in too much fire-heat for numbers of Orchids, and this species and others nearly related are not any the better for the high temperatures often kept up where they are grown. It comes naturally from considerable altitudes, and where, of course, the air is strong; its habit of declining under cultivation is not therefore to be wondered at when it is introduced to hot, stuffy houses. But cool temperatures alone will not make these *Laelias* an entire success under cultivation. In one of the largest Orchid nurseries recently I noted many species usually grown in strong heat relegated to cool quarters, this and the nearly related *L. pumila* among the number. Many kinds considered difficult to grow were in capital health, but the present species did not look particularly happy.

The best-grown plants I have ever seen were in a very limited collection of Orchids, and their treatment was briefly as follows: The plants on arrival, from whatever source they came, were kept in a cool, moist house for a time, and when growth appeared imminent they were taken out of their pots or baskets and thoroughly washed free of every particle of compost, the leaves and bulbs carefully sponged, and every bit of decay, whether of root or growth, cut out. They were then placed in small pans of clean crocks, bringing the latter right up to the base of the leads, using the top layer in a very finely broken state. These were kept moist, and the disturbance seemed to have the effect of causing root emission. As soon as the least sign of this was noticed the plants were carefully watched—a little compost was hid in in place of the upper layer of crocks. Plants occasion-

ally died under the treatment, but these would probably have done little good in any case. The majority came away strongly enough, especially those that had not long been imported. They were kept in the cool house and watered only very moderately until the growths were getting strong, when the plants were removed to a warmer house. Here they remained until they bloomed or until it was evident that the growths were not going to flower, after which they again went back to the cool house. Respecting the time of removal, this would depend entirely upon the state of the plants themselves, but, as a rule, the species named above was returned to the cool house by the middle of September. The extra warmth at the time named seemed to exactly suit the plants, and after the thorough cleansing they seldom needed repotting for three or four seasons at least, though a little of the surface material was replenished annually. All these small kinds require a perfect grip, as it were, of the compost, and they cannot thrive or flower freely without it. Even if they grow out over the side of the pans a little, no great harm is done, though this must not be allowed to go on too long, and great care is necessary to prevent insects eating the roots. The small white scale, so destructive to even large *Cattleyas* and *Laelias*, is doubly so to these small species, and cleanliness, therefore, is one of the first aids to health. When the bulbs are ripe and plump, not much water is needed in winter; it is the badly ripened and weak bulbs that suffer. In any case shrivelling must be avoided, as weakening in the extreme. *L. Dayana* is often described as a variety of *L. pumila*, but it is distinct as a garden plant owing not only to the colour but the shape of the flower being different. It was introduced into this country by Messrs. Hugh Low and Co. in 1876.

H. R.

Cypripedium vexillarium.—This pretty hybrid is now well known, and shows in a marked degree the influence of *C. Fairieanum*, one of its parents. The other parent is *C. barbatum*, and this it resembles in habit. The pretty drooping petals are a pleasing combination of white, green, and purple, the dorsal sepal is like that of a good *C. barbatum*, and the pouch is deep brownish red. These hybrids from *C. Fairieanum* have an especial interest, as this beautiful species seems as far off as ever from being rediscovered or introduced in quantity. A nice plant is now in flower at Bocking Place, Braintree.

Nanodes Medusæ.—This singular Orchid thrives best in quite a cool, moist house, and the flowers are now open. They can hardly be described as beautiful, but their peculiar aspect against the dull green of the foliage and the long purple fringe of the lip is not without its charm. It does well suspended from the roof glass in baskets of medium size, well drained, in a compost consisting of peat and Sphagnum Moss. During the winter months no great amount of moisture is necessary, but still the plant must not be altogether dry. While growing freely it requires a very large supply.

Cypripedium lævigatum.—This is a beautiful species when well grown, the tall, handsome foliage adding much to the appearance of the plant. This is broad and fleshy, deep shining green, the scapes about four-flowered and 18 inches or so in height. The dorsal sepal is white, striped with purple; the long twisted petals, green, white, and yellow, more or less spotted with reddish brown; the lip yellow. In the Philippine Islands this fine species grows in company with *Vanda Batemanni*, so is naturally exposed to a high temperature. This has usually been repeated under cultivation, but quite recently in a large trade collection I noted some immense growths of it in a house where nearly all the *Cypripediums*

were doing well. There is no doubt that many kinds found in some of the hottest regions are none the better for too much heat when brought under cultivation. All these *Cypripedes* without a doubt like an atmosphere moistened almost to saturation point, so that the tiny dew-like drops can be seen on the foliage in the morning. They like plenty of new compost, too, for it must not be lost sight of that they are grosser feeding than many Orchids, and to leave them year after year in the same pots, with the roots drawing all the nutriment out the first year, is bound to lead to starvation.—H. R.

Masdevallias at Bocking Place.—There is a very interesting collection of *Masdevallias* here, including very many rare forms of some of the smaller species, and though not many were in flower on a recent visit, those in bloom were of great interest. All are grown in a small lean-to house, and this is filled to repletion. One of the most noticeable is the beautiful though malodorous *M. velifera*, a fine form, with the characteristic yellowish flowers, closely covered with minute brownish red dots; the shape of the flower, too, is very distinct. *M. muscosa* is also in full flower, this species being singular in the possession of downy stems and a sensitive lip, that when touched by a fine straw or pencil immediately springs up to the column. It is a rare and interesting species. The lovely little *M. ionocharis* is also in flower, as is *M. radiosa*, one of the prettiest of the *M. Chimara* section. The Peruvian *M. civilis* has a distinct colour, the ground tint being yellow externally and purple within, the tails greenish yellow. It is not often seen in good condition. Others in flower are *M. Schröderiana*, *M. inflata*, *M. melanoxantha* and the distinct *M. peristeria*, while the pretty little *Scopiosepalum gibberosum* was also noted. Many of the very tiny section, such as *M. troglodytes*, were flowering, but space will not permit a full description of these.

Epidendrum raniferum.—This is one of the prettiest of the erect-stemmed *Epidendrums*, and makes a bright bit of colour just now. I recently noticed a fine and well-grown plant of it with several spikes of flower in the collection of Mr. S. Courtauld at Bocking Place, Braintree. The blossoms occur in large, loose, semi-erect racemes, and are individually about 2 inches across. The sepals and petals are pale green, spotted with reddish brown, the lip deeply cut into four lobes, the basal pair similar in colour to the sepals, the front ones and column white, the latter lightly spotted with purple. *E. raniferum* likes a rough compost and a fair amount of pot room, good drainage, and careful handling. It is not by any means difficult to grow; on the contrary, it is an Orchid that anyone may cultivate with ease, but it is a mistake to be pulling it about at the roots oftener than can possibly be avoided. Being a native of Mexico it does not require great heat, but delights in ample atmospheric moisture and a light, airy position. Water freely all the time the growth is active, and if the plant can be induced to take a thorough rest in winter the flowers will be more freely produced. It is a very variable species, owing possibly to the fact that it is found growing in a state of Nature over a very large district.

Masdevallia triaristella.—Though one of the smallest of Orchids, this little plant with its tiny flowers is of considerable beauty and interest. The entire plant seldom grows more than 3 inches high, and consists of small terete leaves and carries brownish flowers on almost invisible stalks. The culture of this little species requires care, but there is no special difficulty about it. A very frequent cause of failure is letting the compost get hard and firm through continuous waterings before removing it and giving new material. Disturbance should not be too frequent, of course, but repotting should take place before the compost sours. Healthy roots soon get hold of the new material, but when they have lost a good deal of their vigour, owing to being left too long, they do not take kindly to the compost, and the disturbance is put down as

the cause of failure. Small pots or pans only are needed, the usual mixture of peat and Moss making a good compost, while the present is as suitable a time as any for the work. Remove with a pointed stick all the worn-out material from about the base of the plant, as, unless this is done, the mossy surface soon spreads over the new compost. Water with care after potting, but avoid a dry state of the atmosphere. Keep the plants in the cool house the year through, and never unduly dry the roots. *M. triaristella* is a native of New Grenada and was introduced in 1876.

DENDROBIUM APHRODITE.

ALTHOUGH the blossoms of this *Dendrobe* are not very large, they are very bright and pretty; its season of flowering, too, is greatly in its favour. At first sight the plant looks a good deal like a small *D. Findleyanum*, owing to the swollen nodes of the stems, and it was this circumstance that led Dr. Lindley to name the species *D. nodatum*, that given above being the name that Professor Reichenbach had previously described it under. The growths are seldom more than 8 inches high and the blossoms are produced in pairs—seldom three—from the upper portion. These are each about 2 inches across, the sepals and petals creamy white, the lip roundish, yellow in front, and having two bright maroon blotches at the base. As these flowers occur on the old stems, as well as the last ripened ones, a very bright and showy effect is gained. *D. Aphrodite* is rather more difficult to keep in health than some other kinds, especially if weak plants are procured. A healthy specimen is worth keeping in health, but small bits seldom make good plants under cultivation. The plants do best in baskets or on pieces of Tree Fern stems that can be kept well up to the light, both for the sake of ripening the growth and preventing damping of the young shoots when starting. It does not like much compost about the roots, an inch of good peat fibre and Moss being ample for a medium-sized basketful, while the natural roughness of the Fern stems is sufficient for it when grown in this way. The stems may be cut into lengths of about a foot, and the plant so disposed that the stem may be suspended horizontally, this allowing the growth to get the full benefit of light and air. The baskets are, of course, just as good in this way, but they lead to more frequent disturbance of the plant, and this is not desirable. Water must never be too liberally supplied, especially during the winter months. When growing freely in a light, warm house they dry rapidly of course, but not so rapidly when grown as above as do others of the crassinode and similar kinds growing in small pans. Light dampings overhead are very helpful in keeping down the small yellow thrips that attack this, *D. albosanguineum*, and similar species. It will often be found to grow out of the regular *Dendrobe* season, so that in treating it as to temperature regard must be had to the state of growth. The more it grows in summer the better, but, as a rule, the summer-made growths are not forward enough to flower the first season. *D. Aphrodite* was introduced into this country by Messrs. Low and Co., and is a native of Moulmein.

Cypripedium Mrs. F. L. Ames.—This is a distinct hybrid, raised in Mr. Ames' collection in America. It is the result of crossing *C. tonsum* with *C. Fairieanum*. The dorsal sepal is upwards of 2½ inches in breadth and of similar depth. The ground colour of the upper portion is white, with a suffusion of delicate rose, shading to pale green at the base. It is lined from the base to the apex with numerous dark brown lines. The petals are each 3 inches in length by an inch in breadth. They show the deflexed characteristics of *C. Fairieanum*, are pale green, suffused with rose on the corrugated margin and towards the apex. There are numerous dark lines, with some spotting towards the base. The lip is pale green, suffused with rich brown. It resembles *C. vexil-*

larium in many respects, but it is lighter and altogether larger than that variety. A plant was recently exhibited at the Drill Hall from the collection of Mr. O. O. Wrigley.

Dendrobium atrovioleaceum.—This lovely species was introduced by Messrs. J. Veitch and Sons, Ltd., about 1890 through the late David Burke, who discovered it on one of the small islands in the region of New Guinea. It first flowered in this country in Messrs. Veitch's nursery, on which occasion it was, when exhibited before the Orchid committee of the Royal Horticultural Society, awarded a botanical certificate. Little more was heard of this remarkable plant; in fact, I remember having had instructions to burn a considerable proportion of the importation, the introducers having little demand, or thinking evidently little of it themselves until a plant flowered in the collection of Sir F. Wigan at Clare Lawn, East Sheen. This plant was exhibited January 16, 1891, when it was awarded a first-class certificate. The plant carried a raceme of eight expanded flowers and four buds. It was in great demand from that time, but, unfortunately, the majority of the plants that had been retained by Messrs. Veitch had died in the meantime, although high prices were given for what few remained. It has been exhibited on several occasions since the plant was certificated, and each time it has been one of the chief subjects of admiration. The sepals and petals are pale creamy yellow, spotted with violet-purple and dusky brown. The lip is a very deep violet-purple, marbled with pale greenish yellow markings. The flowers last in perfection several weeks. It requires an abundance of heat and moisture, and should be placed in a light position near the roof glass. Shallow pans are the most suitable for it; these should only be sufficiently large to get the plant into comfortably. The less material there is about the roots the better, as they are subject, like those of most other varieties of the *D. macrophyllum* section to which it belongs, to rot off at the base whenever there is the least stagnation.—H. J. C.

NOTES AND QUESTIONS.—ORCHIDS.

Masdevallia Lindeni.—There is scarcely any difference between this species and forms of *M. coccinea* (Harrayana). The colour is similar to that of the variety known as *M. H. conchiflora*, but the flower is a little different in structure. The upper sepal has the habit of bending backwards behind the body of the flower. In every other respect it is similar to *M. coccinea*, and there is no doubt it is only a variety of that species.—H. J. C.

Maxillaria nigrescens.—There is a fine specimen of this species now in bloom in Mr. S. Courtauld's garden at Bocking Place, Essex. It is carrying about thirty of the pretty and singular flowers. The petals are a very deep vinous red, the sepals only very little lighter, the lip deep purple. Like most other *Maxillarias*, this species may be well grown in an intermediate temperature, with abundance of atmospheric moisture and plenty of water at the roots while growing. During the resting season it must never be entirely dry. For compost use two-thirds of peat to one of Moss, and a little loam for the strongest plants. It is a native of Merida, and was discovered in 1842.

Cælogyne speciosa.—This is an old but by no means an unattractive species, and I have noted it flowering in quite a number of collections recently. The habit of the plant is strong and the flowers are perhaps the largest in the genus, though produced on few-flowered scapes. The lip is large and oblong, strongly marked with deep brown ridges of hairs running the entire length; the sepals and petals are smaller, pale yellow. It does well in a shady corner of an intermediate house, and should be grown in pans or pots in peat and Moss, with a little half-decayed leaf soil added. It is a native of Java, where it grows at a considerable elevation, and was introduced in 1846.—H.

FERNS.

BRANCHING TREE FERNS.

THE photo of branching Tree Ferns (*Alsophila* sp.) from which the illustration was prepared was taken on the slopes of the outer range of the Himalayas above the Government Cinchona plantation at Mungpoo, near Darjeeling. They are frequently met with there, and grow to 60 feet high sometimes. The road from Dar-

jeeling to Mungpoo is a most delightful one. In one of the valleys I passed were quantities of *Magnolia Campbelli* in full bloom—a grand sight. I also saw a mass of *Cecylogyne corymbosa* in full flower on the branch of an evergreen Oak. This was at an elevation of about 7500 feet. It is a beautiful Orchid. In the dense forest the trees are covered with *Cymbidiums*. In another valley at a lower elevation I saw quantities of *Vanda Cathartii*, and on one occasion I saw these in full flower. The

plants were hanging over a rushing torrent, the sides of which were boulders covered with *Hymenophyllums* and shade-loving Ferns, growing in the greatest luxuriance. The walk from Darjeeling to Mungpoo is well worth the trouble, and now-a-days easy to do. I spent last Christmas in Kumou, in the North-west Provinces of India. I saw here *Cecylogyne cristata* at 5000 feet growing over ground frozen at mid-day, and some of the pieces I cut off the trees were full of icicles.

producing large well-furnished plants it should be grown in a position where nothing else can touch the ends of the fronds, for these once bruised die back and the pretty tasseled appendages are lost. The house where it is grown should not be too hot or moist, or the growth is not so satisfactory. The pots should be large enough to allow of the plants extending their rhizomes freely, and a more rapid growth is ensured by using the compost in a very open, rough condition, large lumps of charcoal being introduced with the loam and peat. The fronds must be tied up and the base of the plant kept well up when potting, as it is natural for the plant to push vigorous above-ground rhizomes. Water must be very freely allowed, few Ferns needing more moisture at the root. In hot weather well rooted plants may be stood in deep saucers or pans of water, this preventing flagging of the fronds.

Branching Tree Ferns in the Himalayas. From a photograph sent by Mr. C. Maries.

In the dense forest the trees are covered with *Cymbidiums*. In another valley at a lower elevation I saw quantities of *Vanda Cathartii*, and on one occasion I saw these in full flower. The

Judging from the number of old flower-spikes they were thriving well in the cold.

C. MARIES.

Microlepia hirta cristata.—This is one of the finest of exhibition Ferns when grown to large specimens, and these are soon produced owing to its tree habit of growth. It is also very beautiful in a small state for grouping or indoor decoration, the fronds standing well in a cool place where more delicate species would not. For

produced in our gardens! A really pale shade of blue is beautiful on grass, as the spring Forget-me-nots show us, but the full, rich blue of *Lobelia* next green grass, next red, or next yellow is atrocious, and yet how rarely is it otherwise used. Do let us stir up those who have eyes to see and tongues to talk to protest against this misuse of blue *Lobelia*, which is really at the root of the dish-like to summer bedding, which is growing day by day on account of the carelessness and bad taste so often

FLOWER GARDEN.

THE ABUSE OF BLUE LOBELIA.

At this charming season of the year, when the summer bedding garden is at its best, how often is the effect of what would otherwise be a brilliant and tasteful garden entirely spoiled by one plant, and that a very pretty one in itself. A few years ago men of taste and perception protested loudly against the over-use and wrong use of the *Pyrethrum Golden Feather*, which, save in spring-time, is really a plant to be avoided rather than planted for ornament. Thanks, no doubt, to folks' eyes being opened, one sees comparatively little of this plant now, so I need say no more about it to-day; but the blue *Lobelia*, the plant to which I now prefer the grievous charge of spoiling many a pretty garden, is so charming in itself, that its constant misuse demands a strong protest.

It is not too much to affirm positively that in the hundreds of gardens, great and small, that I have seen lately, blue *Lobelia* is used as an edging to three-quarters of the beds that are filled with summer-bedding plants, and yet there is never a broad mass of rich blue to catch the eye and fill it with a sense of repose. Take even the London parks, where sometimes one sees what wonders really good taste can work, and yet how often will you see a bed edged with blue *Lobelia*, which not only "swears" generally with the flowers it surrounds, but invariably disturbs the eye where it touches the green grass. Modern milliners no doubt have been busily trying to persuade us that grass-green and a hard blue are fashionable as a combination; but they cannot convince us it is good taste and a thing to be admired. What a pity then it should be so constantly reproduced in our gardens! A really pale shade of blue is beautiful on grass, as the spring Forget-me-nots show us, but the full, rich blue of *Lobelia* next green grass, next red, or next yellow is atrocious, and yet how rarely is it otherwise used. Do let us stir up those who have eyes to see and tongues to talk to protest against this misuse of blue *Lobelia*, which is really at the root of the dish-like to summer bedding, which is growing day by day on account of the carelessness and bad taste so often

displayed by those who should know better. Nothing is more charming than a broad mass of blue when properly treated, but full, rich blue absorbs so much light that it requires plenty of white, or, still better, cream colour to set it off. There is now plenty of dwarf white-flowered or creamy-foliaged plants suitable for edging blue Lobelia. Why not use them for an edging and put the blue inside? A rich orange or a tawny brown, such as *Gazania* or brown *Calceolaria* give, is most effective near blue when the latter is edged with a creamy-toned plant. *Echeverias* with their bright flowers left on are particularly suitable for edging Lobelia. White and blue in mixture, or white grouped or dotted on blue is always admissible. What a relief to the eye would be a good mass of blue and white as a central object in small gardens now vulgarised by a constant repetition of reds, yellows and blues, and what a satisfaction it would be if anyone would just plant half his garden in the way I have indicated and the other half in the usual blue-edged uniform. I feel sure the difference in beauty and brilliancy would be so great, that another year I should have converted him from the error of his ways. E. H. W.

Oxalis enneaphylla.—Prior to the opening of the flowers of this plant, there is some resemblance in growth to the well-known *Tropaeolum polyphyllum*, more particularly when this latter has sent up numerous growths from below. Any apparent resemblance, however, vanishes when the large pure white blossoms of the *Oxalis* appear, very large indeed compared with the general character of the plant, and showy withal. Nestling at the base of a large block of stone, this handsome subject has attracted a good deal of attention this year in the rock garden at Kew.—E. J.

Alstroemeria pelegrina.—Although this is not so beautiful as some of the other kinds, still it is a useful border flower. The colours are distinct from those of most things blooming at the same season, and may be described as reddish purple outside, inside white, streaked and veined with reddish purple. This is useful for decoration when associated with some other suitable white flowers and greenery. Another of its merits is that it follows *aurantiaca* in blooming, and at the present time (August 20) it is in fine flower, growing amongst other perennials in a warm south border. I am aware it is considered tender. All the same it thrives amazingly in this position with a little leaf-mould over it in winter.—Dorset.

Seedling Pentstemons.—In the series of these beautiful flowers brought to the Drill Hall recently from the garden of Sir Trevor Lawrence at Dorking we saw more than the mere display the blossoms themselves gave; it showed the value of raising such things from seeds each year instead of trusting to the more troublesome and expensive method of raising cuttings in the previous autumn. This alone should prove an incentive to many to grow these things in this way, because any who possess no greenhouse will be glad to know that a warm manure frame will do just as well for such comparatively hardy subjects. The most important point to attend to in raising such things—and it applies equally to cuttings as to seedlings in every department of gardening—is to push the young plants on as rapidly as possible from the very start. It is in this that much time is lost, and irretrievably so, for in cuttings that have become hide-bound, so to speak, the ready flow of sap to the plant must of necessity be checked, and in this way development is curtailed. This occurring in the young stage causes a starved condition, puny growth, and so forth; therefore no more important item exists with respect to the young plant. The seeds of the Pentstemons referred to were sown on January 29 of the present year, and fine exhibition spikes resulted in August and September ensuing. Such a result should

alone speak volumes for seed-raising in such a case, and it is in this way that exhibits, small and unimportant though they be alone, become a source of instruction to many. But to make these things wholly instructive and to show why they are shown, good-sized cards should display their object to the visitor, who perhaps may only regard them as but a few Pentstemons after all.—E. J.

THE REVIVAL OF THE HOLLYHOCK.

ONE of the most telling object-lessons yet seen of the return of the Hollyhock to its old place of honour and of power in our gardens may be found in the large and very striking use of single Hollyhocks in the Regent's Park, London, this year. Amid all the beds, groups and borders profusely filled and more or less skilfully massed, and the large well-filled vases which possibly are unrivalled in London or any other city, the single Hollyhocks tower above all in their simple dignity and stately grandeur. As one stands delighted in full view of these glowing masses of colour one can but wonder at the decline and fall of single Hollyhocks in our gardens. Not but that room enough and to spare might well have been found for both in most gardens. But surely from the artistic and picturesque point of view the singles are the more telling and effective. Their stature, exceeds that of the doubles, often weakened and enfeebled by excessive cultivation and incessant coddling which render them the easy prey of the Hollyhock fungus (*Puccinea malvacearum*). Probably this disease drove many cultivators back to single Hollyhocks, the double going down in battalions before the touch of the dire disease, and it became plain to many growers that their choice lay between single Hollyhocks or none. It seemed a cruel necessity at the time, but so far as the future of our gardens and landscapes is concerned, this dilemma may, like many other trials, prove a blessing in disguise. Should any growers for broad effects in landscapes doubt this, a careful study of the rich and grand effects of single Hollyhocks in the Regent's Park will almost certainly convince them to the contrary.

Most of us have grown Hollyhocks in lines, groups, or masses of more or less length and breadth, but when we see them massed in scores—fifties, hundreds, probably thousands—they rise in dignity, stature, grandeur, and cumulative force far beyond the mere actual increase of their numbers. Next to their great mass, which gives them such weight amid the trees, shrub foliage, and flowering plants, which are on the whole so skilfully used to enrich and adorn these gardens, the towering height of the single Hollyhocks is one of the most telling and valuable features. To many eyes and minds the effect of much of our general furnishing and the whole of our formal carpet bedding spoilt or greatly marred by its flatness or uniformity. The single Hollyhock rushes boldly through all this with a bound, and he would be at once a bold, presumptuous, and balled grower who should endeavour to mould the height of his single Hollyhocks with rod and line. The variety of height is almost as great as the variation of colour, the two together going far, by breaking out in the most unexpected places and forms, to constitute some of the chief charms of beds, groups, borders of single Hollyhocks. But this change of fashion from double to single will also have far-reaching results in adding to the health, vigour, and longevity of our Hollyhocks. The development or evolution of single Hollyhocks into double flowers is in itself a source of weakness. It also shows no lack of propagation by eyes, cuttings, budding, or grafting of either roots or tops or stems, all of which are more or less enfeebling, whereas in single flowers one may fall back on seeds as the chief or only means of propagating, for it is not necessary that even the finest single stocks should be propagated by the same methods as double varieties.

For artistic and distant effects, single Hollyhocks are best massed alone. But in most gar-

dens and all our parks abundant space may also be found for doubles. On sanitary as well as artistic grounds, the two sorts, singles and doubles, are best grown separately, and when so grown it is often found that the singles are more free from the rust, while the doubles are more or less infected. Of course, I am well aware that careful culture and copious watering are good antidotes to the Hollyhock fungus, but I have more faith in growing it entirely out through the general culture of single varieties. Neither is it at all certain that we have exhausted the capacity of single Hollyhocks to give us yet higher, brighter, and richer and more vari-coloured—perhaps flaked and bizarred—blooms, as well as yet taller and more branched flower-stems.

D. T. F.

CACTUS DAHLIAS.

EVERY year is bringing into prominence new and beautiful varieties of these Dahlias. It is true they are not, for garden decoration, all that can be desired, but great efforts are being made to improve them in that respect. Still, the flowers are chiefly to be regarded first for the possession of particular and quaint features, and second, their properties for exhibition. Cactus Dahlias are yet but in their infancy, and even the most enthusiastic raisers have been surprised to find what odd and yet singularly beautiful forms they assume. When some clearly defined and set form is once produced—and it may be a long time hence—then will it be possible to improve on their garden characters. Already the earlier varieties, such as *Juarez*, for instance, the pioneer of the family, have practically disappeared from exhibitions. New ones are rapidly propagated, and thus they come into commerce. The present season will doubtless see a dozen really remarkably beautiful forms added, and it is hoped that the executive of the National Dahlia Society will withdraw others from their list of recognised varieties, so that instead of unduly multiplying there may be such constant revision as shall keep this list within due bounds. It does seem as if for show—and it is doubtful whether there are any more beautiful flowers for that purpose, as usually displayed—it will be needful presently to make two divisions. We have flowers of the most attractive form, having long, narrow pointed petals, that stand out from the centre of the bloom quite horizontally. Of these very perfect examples are found in Charles Woodbridge and Mr. Stradwick's new buff-coloured *Magnificent*, a rather pretentious name for what is all the same a very perfect flower. Then there is a growing section that has distinctly incurved petals, and Mr. Burrell's *Fantasy*, one of the quaintest of its kind, has apparently something to do with its production. At the recent exhibition of the National Society at the Crystal Palace there was a close division of opinion as to whether the special prize given for the best bunch of any new variety in the show should go to *Magnificent* or to Mr. Burrell's *Lucius*, a beautiful variety of the incurved form, and the latter eventually won, the judges evidently liking the less formal and more true Cactus character found in the incurved petals. But both these fine flowers serve well to show the nature of the advances being made in form in these Dahlias. But even the best of to-day cannot hope for any enduring existence. Like the Japanese *Chrysanthemum*, they come, are popular for a season or two, then have to give place to others that excel them, and no doubt it is best it should be so, for finality in Dahlias or in any other flower would soon mean death. Just as the Japanese *Chrysanthemum* with its constant additions and improvements has given

to the whole family a new lease of life, so also has the introduction of the Cactus Dahlia given to the whole family a renewed run of popularity. For one who grows the large show kinds there are twenty who grow the Cactus varieties. It is worthy of note that whilst the National Dahlia Society annually publishes a list of those varieties that alone are, exclusive of seedlings, admissible as Cactus forms at its own shows, no such selection governs competitions in other directions. Of course, the National Society has no power to compel other bodies to adopt its classification, but very much might be done to avoid unpleasant *contretemps* could the National executive induce the committees of provincial shows to mention in their schedules

Puschkinia scilloïdes.

where competitions in Cactus varieties are invited that the flowers shown must be included in the National list. That would compel judges to make themselves familiar with what are really Cactus varieties and save them from some unhappy decisions.

Many fine seedlings, exhibited both at the Crystal Palace and the Royal Aquarium, may be left over for further notice. A first-class dozen now in commerce and obtainable next season at moderate prices are Keynes' White, the purest white, though not a perfect-formed variety; Daffodil, very slightly paler than Lady Penzance, primrose-yellow and of superior form; Arachne, petals somewhat incurved, rosy red on cream; Starfish, a beautiful salmon-scarlet; A. J. Deal, rich scarlet; Cycle, crimson-scarlet, very effective, but needing more refinement; Charles Woodbridge, colour rich crimson, a superb variety; Cinderella, claret, shaded crimson and rose; and Night, richer maroon than Matchless, petals partially incurved. So far it will be difficult to beat this selection for exhibition. A. D.

Phygelius capensis.—It is only within the last week or two that this showy plant has assumed its usual effective character in my garden. This has been due to the way in which its earlier shoots were attacked by a slug-like pest I have not seen here before and which has attacked no other plant here. Only a few spikes came into flower and the whole plant looked very disconsolate. The same has been the case at Kirkeconell, Newabbey, this year. Now fresh growths have been made and the Phygelius is as pretty as usual. I have up till now grown it as a bush on the rockery, but I saw it as a wall plant at Glasnevin. Mr. Moore thinks this the best

way to grow it, and on the wall it looked more effective than I have ever seen it in bush form.—S. ANSOTT, *Carsathorn, by Dunfries.*

PUSCHKINIA SCILLOIDES.

THE Puschkinias are among the fairest and most beautiful of spring flowers. It is not easy accurately to convey an idea of the beauty of the colouring in these spring bulbous flowers to those unacquainted with their charms, seeing the blossoms are white and lined with blue, or perhaps merely tinged with blue in some instances, for so many things may be of this class, and the love for striped and indecisive flowers is not great. With these Puschkinias there are an unusual charm and delicate beauty, and which but need to be seen once in good condition to be well remembered. Like many other bulbous plants, the Puschkinia is a spring flower, and of course long since past and gone. At the same time the present is an opportune moment for referring to this dainty group, as no better time in the year could be selected for commencing their culture. In short, it is the best season for planting such things, and by so doing to get them well established and ready for flowering early in 1899. When fully established, which is generally in the second year from planting if good bulbs have been secured, the plants will reach 6 inches to 8 inches high. To do these things justice, whether planted in the border or the rock garden, not less than 1 foot deep of good prepared soil should be given, and this always of a very sandy nature. In some few nursery gardens these plants make themselves quite at home in the ordinary soil. It was so in the Tooting nurseries of the late Mr. Robert Parker, where upwards of twenty-five years ago I had charge of a splendid row of the plant that when in growth stretched out nearly a foot in width and more than 9 inches high. This was a splendid sight when in flower, and when lifted contained a fine lot of bulbs, besides producing a goodly and welcome batch of seeds. A subsequent lot planted from this and treated with rough chopped peat and loam, the whole made very sandy, also did finely; in each case the bulbs were on the level ground in open beds, nor was the soil reduced by a surface covering of carpet plants. These small bulbous plants many of them are much deeper rooting when opportunity affords than is usually supposed, and for this reason when plants are placed in the rock garden some care should be given to securing a good depth of soil for the roots. Where clay soil exists special soil will have to be given such things, the most important matter being to secure perfectly free drainage. Where old clumps exist these may now be divided and replanted without further ado, for I have yet to learn that such things are benefited generally by long keeping out of the earth. Proof of the undesirability of this may be had in the *Chionodoxas* at times, which, together with the plant under notice, when kept long dry only attain half their usual height when planted. A year later a much greater vigour is secured, as the result of the bulbs not being disturbed. This fact speaks for itself, and, assuming there is no deterioration, the bulbs may be left alone for at least four years, and give the best returns by so doing, provided due preparation was made at the start. Where the soil is very light such things may be planted fully 4 inches or 5 inches deep, distributing the bulbs rather thinly. The bulbs are small, rather roundish and fleshy, starting into growth quite early in the year and flowering in April. The flowers are somewhat numerously produced on a rather

densely set spike, more erect both in growth and flower than is conveyed by the accompanying illustration, which may possibly have been taken from bulbs of small size. There is a more compact-growing form distinguished by the name, while the plant is known by the synonyms of *P. libanotica* and *P. l. compacta*, *P. sicula*, &c.

Seeds of this pretty plant are freely produced from good bulbs, and by securing these and sowing in shallow drills in the open ground in well-prepared soil, a nice stock may soon be obtained. The seedlings are quite safe for a couple of years, when they may be replanted with more room, though on similar lines, till flowering is reached. E. J.

HARDY CYCLAMENS.

Few hardy plants have a prettier effect than the varying members of the hardy Cyclamens, which in their flowering cover a very considerable period, commencing, as it were, with the forms of *C. europæum* soon after midsummer and concluding with *C. repandum* in April or thereabouts. When the corms have attained to a large size—and some of them reach 6 inches or 8 inches across with age—the plants are singularly attractive, both by their foliage and the numerous dainty flowers which they produce. In point of culture there are but few items to be observed, the chief of these being a let-alone system when once planted. This is, perhaps, not so essential in the younger and smaller corms as it is when these have attained their maximum. A circumstance bearing on this will suffice to prove what in practice has already been apparent. In looking through some cottage gardens on the outskirts of Kidderminster some years ago I got into conversation with an old sexton who had found a quantity of what proved to be *Cyclamen europæum* growing wild, as he said, in a small copse less than a quarter of a mile from his dwelling. We went together to the spot, which was certainly an ideal one for these plants, but I endeavoured to impress my companion that seeds or bulbs must have been

Cyclamen corm.

deposited where he found them. He was specially anxious I should have a root to compare with my own stock, which he would send me when fit for removal. But though I particularly requested that he should only send a corm of medium size, he sent me what must have been the largest he possessed—giant roots upwards of 6 inches across. Notwithstanding that more than ordinary care was taken in planting, this fine corm, the growth of years, gradually dwindled away, a circumstance as much due perhaps to the age as to the length of time the bulb had been in its position without disturbance. Such very large roots, however, are by no means common; indeed, only one or two kinds ever reach the size named so far as my experience goes. The

position where these were originally found was a plantation of Larch not over thick at the time which I speak, a sharp sloping bank to the south, the soil somewhat sandy and light and freely mingled with red sandstone chips. The same species, *C. europæum*, grows quite vigorously in soil which is just the opposite in some parts of Gloucestershire, viz. in a rather heavy clay, mixed, however, with small gravel from the inferior oolite marl, which assisted drainage to a considerable extent. In the garden of the late Mr. James Atkins in the same county, where considerable attention was paid to these hardy Cyclamens, the soil was of a different character and the position much higher also, yet the growth and flowering were all one could desire. Indeed, in midwinter I have seen patches of foliage from the lovely *C. neapolitanum*, of which any garden may be justly proud, spreading out a yard or more across. These diverse circumstances of growth are mentioned to show that these things are by no means fastidious as to soil; indeed, so long as good drainage is given them the soil is of quite secondary importance. At the same time I would suggest that a heavy clay soil be liberally treated with old mortar rubbish and leaf-soil together with being deeply dug also. Given this, these pretty plants may adorn the rock garden, the border, or the hardy fernery, and if planted in groups make a pretty and attractive feature.

The species of which we have an illustration to-day is one of the dwarfest of the genus. It is also one of the most showy in point of colour, even though small in size, while the firm texture of the smooth, round leaves renders it distinct from all else in this genus. The type species has flowers of a bright crimson; there are also varieties having rose-coloured and white flowers respectively. All these have a preference for partial shade, and are somewhat more lasting when in such a position. It is a native of Southern Europe and Asia Minor, and may be transplanted from June to September, when dry roots are easily obtainable in plenty. Pot plants, of course, may be dealt with at any time. *C. europæum* flowers during late summer, commencing in the end of July. As a rule, the flowers of this are much larger and more pointed in the segments, and possessed also of a pleasing and decided fragrance. Some pretty effects may be secured from the foliage of this kind, which is marbled with white above and reddish purple beneath. It is a very old garden plant, yet not so freely cultivated in those positions in the garden which suit it best. *C. ibericum* in point of culture may be regarded from the same standpoint as *C. eoum*, yet in its many and variable forms it is superior to the latter. Some varieties of this species were raised by Mr. Atkins in his Painswick garden and bear his name. Of this species there are red, rose and lilac varieties, and a charming white kind with crimson base which is known as *C. i. Atkinsi*. *C. neapolitanum*, the Ivy-leaved Cyclamen, is among the most attractive of the fine-foliated kinds, the leaves not only handsomely marked, and worth growing for this reason alone, but produced in considerable quantity also, and simply carpeting the earth with their beauty. This kind is also full of vigour, and being obtained at a cheap rate, worthy of being freely introduced to rock garden and woodland. In the latter, however, some clearance will be needed where strong herbage abounds. There are rosy pink and white forms of this beautiful plant, and with *C. græcum*, which is also covered with beautiful foliage in autumn and winter, are among the most charming of this pretty race of plants.

In making permanent groups of these, a depth of 3 inches or 4 inches is usually sufficient covering. *C. africanum* and *C. repandum* should be planted in the more sheltered places and covered with leaves during the winter. The above with *C. cilicium*, a prettily formed flower, are all worth attention in the garden, for though some of them closely imitate other species or forms in their flowers, they do not all appear at the same season, which is an item worth remembering in a group with so many attractions. In all but the lightest of soils, old mortar rubbish to the extent of one-third may be added to the soil with advantage when planting, and where the soil is of good depth the plants will be safe for years. E. J.

FLOWER GARDEN NOTES.

PENTSTEMONS.—The various blocks of *Pentstemon glaxioides* sown early in 1897 were at the end of that season looking fresh and well, and showing such sign of breaking away vigorously, that I decided to let them remain, mulching between them with good manure. The result, however, has not been satisfactory, and in future I should always treat this as an annual, sowing early in the season and removing at the end of the year. I have a nice batch to hand from seed of the hardy varieties *barbatus*, *coccineus*, and *glaber*, and these will shortly be planted in bold clumps in a large bed, intervening spaces being filled in with Tufted Pansy Violette. Another bed about the same size, planted in a similar manner, which is likely to make a good show, will consist of Melton and Ormonde Pyrethrums, with a groundwork of Albino Pink. Another very effective contrast is furnished by *Aphrodite Pyrethrum*, a remarkably fine white, associated with a dark purple *Viola*. Another bed will be planted with a batch of seedling *Gypsophila paniculata*, setting these 2 feet each way to allow of corms of *Montbretia Etoile de Feu* being placed between them. I think this should make a charming combination. In planting beds with early-flowering things it should be remembered, if such beds are to be permanent, that these are over rather quickly, or, more correctly, over early in the summer, and it is therefore a good plan to associate them with some later flowering plant, always of course avoiding an incongruous mixture. That very useful plant, for instance, *Doronicum excelsum*, that everyone should grow largely, is over rather early in the summer, and clumps of this may be alternated with something that will follow in its wake so far as the flowering is concerned. At this season we get a substitute for the *Doronicum* in the splendid *Helenium Miss Mellish*. I do not know what height this attains on good soil; here in light, dry borders the top flowers are between 6 feet and 7 feet from the ground. The long flower-stems allow it to be utilised for tall trumpet vases, and mixed with a bit of feathery foliage it makes a brave show. I am marking some of the herbaceous *Lobelias* this week with the view of future propagation. One does not realise, until a careful inspection is made, that the foliage varies very considerably, in some a green tinge showing in the deeper hue, whilst others, with *Dracæna*-like leaves, show a depth of colour almost approaching Dell's *Crimson Beet*. Possibly where this variation is mixed in rather large blocks it makes little difference to the general appearance of the bed, but if several of the lighter foliated forms are together the difference is at once apparent, and for this reason it is always advisable when propagating to select the deep-coloured plants. I saw a very interesting combination the other day in the shape of a background of these *Lobelias* faced with a good breadth of *Linaria repens* var. *Snowflake*. The latter may be recommended as a splendid dwarf plant for the front of borders. Its tiny *Antirrhinum*-like flowers are produced in great profusion, and the display is long sustained. The *Lobelias* are suffering from the protracted drought, and although watered more than once

are smaller in foliage and shorter in flower-spike than usual. All flowers, indeed, of midsummer have been below their average, and unless rain comes quickly and copiously, later-flowering things will also be seriously affected. It has been the worst season for *Phloxes* that I remember; the big heads of flower were fairly good, but they were quickly over, and the side shoots were weakly, and what little bloom produced was decidedly poor. I have cut most of them down with the hope of obtaining second growth and bloom, but unless I can give them heavy soakings of water, I fear they are not likely to do much good. *Schizostylis coccinea*, one of the many hardy plants THE GARDEN has done much to popularise, is just coming into flower, and what a beautiful thing! As it is standing at a little distance, with the sun shining upon it, there is a delicate satiny appearance, and the colour is very fine. Starworts do not appear to have felt the dry weather so much as most plants, but if the hot, bright weather continues I shall have them in flower earlier than usual, and they will be appreciated for cutting, with *Phloxes* somewhat a failure. Among the best larger flowers for this purpose just at present are *Dahlias*, annual *Asters*, *Salpiglossis*, and *Montbretias*; the last in partial shade are very good.

Charmont.

E. BURRELL.

Dianthus Cyclops.—"E. J." has done well in calling attention to the merits of this handsome single Pink on page 190. I have had it in my garden for some years, and prize it not only for its fine flowers, but also because of the little attention it requires. On a ledge in the rock garden it looks very well, the bright-coloured, dark-eyed flowers being very effective. I have not tried it in a bed, and find it looks healthier on the rockery than on the level. Grown from seed it presents some variation both in the ground colour and in the depth of colouring of the centre.—S. ARNOTT.

FRUIT AND VEGETABLE CROPS.

WESTERN.

Moore Park, Ludlow.—The fruit crops about here vary a good deal, but on the whole we cannot complain. Apples in orchards are very thin, but in gardens many of the trees are bearing good crops of nice clean fruit. I will have a fair crop of good-sized fruit. The same remarks apply to Pears, though in some gardens near here the majority of the trees are without a single fruit, owing to the spring frosts. Apricots are a splendid crop, and had to be thinned to about half. Plums are a very thin crop all round here. Damsons the same. Cherries are good. Peaches on the walls are a good crop. Figs are a failure out of doors. Strawberries have been a grand crop, especially *Royal Sovereign*, *Noble* and *Waterloo*. My neighbours have also had splendid crops of these and other sorts, Dr. Hogg, Latest of All and *Jubilee* coming well to the front, but for preserves *Vicomtesse Héricart de Thury* cannot be beaten here. Raspberries are a fair crop, *Superlative* being grand. I have a local seedling named *Pillar's Seedling*, somewhat like *Superlative*, but with more vigorous growth and larger fruit. This variety has stood the drought well and has borne a splendid crop. Some of my neighbours have had only very small crops, especially on light ground. Gooseberries are only a fair crop, but as a consequence the fruit is very fine. Black, Red and White Currants are plentiful.

Vegetables since the rain are now looking splendid. Peas have not been up to the usual standard owing to the continued drought. Beans, broad, runner and dwarf, are in good condition now, and look like giving an abundant supply. Celery looked short in growth until the rain came, but now it is going ahead. Cabbages never were

better about here. I am now cutting splendid stuff from the second growths, Etampes and Veitch's Earliest of All being the best. Carrots will be a failure owing to the fly. I have had to sow such varieties as Scarlet Model and Early Nantes on early borders to make up the supply. Onions will be a very good crop, especially Tripolis and varieties sown in heat and planted out in May. Potatoes have been splendid this year, and, as far as I can see and hear, are likely to be a heavy crop. The heavy rains we have just experienced may start second growth amongst the early varieties if not harvested, but the late kinds will be benefited. Altogether the season has suited this neighbourhood fairly well.—ALEX. HAGGART.

Forde Abbey, Chard.—In many ways this has been a disappointing season. In the early part of the year many thought things would be extremely forward seeing the weather was so mild, but as the spring advanced this was not so, many things being later than usual. Apricots were the first to bloom, but with me the early blooms were destroyed, yet there is an average crop. The fruit of many kinds is very good, New Early, Largo Royal, Moor Park, and Powell's Late being the best. Cherries bloomed grandly, and Morellos are a magnificent crop. Sweet kinds are not very satisfactory in this garden except on a north wall and growing in a hard border. Strawberries were under average on old beds, but from young plants planted last autumn the crop was very heavy, Royal Sovereign, President, Latest of All, and Kitley's Goliath being the best. Bush fruits have average crops except Raspberries, which will not thrive in this garden. Gooseberries are large and highly flavoured. Black Currants are infested with fly. Plums bloomed abundantly, but the crop is only fair. Some trees dropped all their crop from being so badly attacked with fly; in fact I do not remember ever to have the trees so bad before. My best are Jefferson's, Golden Drop, Victoria, Early Prolific, Magnum Bonum, and Monarch. Pears will be a scanty crop, and I am afraid the size will be below average. The trees bloomed abundantly, the fruit swelled up to a good size and then dropped off. My best kinds are the old Crassane, B. Clairgeau, Emilo d'Heyst, and Marie Louise. Apples are an average crop. Some trees have dropped the greater part of their fruit. Nuts are above average; Walnuts average, and hedge Nuts a heavy crop.

The dry weather is having its effect on the Potato crop, more especially where the land is poor and badly worked, and the crop will be very thin. In this garden the crops are grand.—J. CROOK.

Stoke Edith Gardens, Hereford.—The fruit crops here are, with the exception of Plums, very satisfactory indeed, and after reading the reports received from various parts of the country contained in the horticultural press we have just cause to congratulate ourselves upon the fact. Plums, as has just been mentioned, are the least satisfactory, some sorts bearing well, while others are but scantily cropped. Early Prolific, Orleans, Czar, Jefferson's, Red Magnum Bonum and Golden Drop are the heaviest laden, and Green Gages are fair. Damsons will not come up to expectations. Apples are a heavy crop, the fruits being clean, well developed and large for the time of year. Thanks to the good effects of the winter dressings which the trees receive annually, insects have given but little trouble. The heavy rains which fell at the latter end of May and again early in June no doubt did a good deal towards saving the crop, as but few fruits dropped when compared with other places. Rain is again wanted for the late sorts, and it is to be feared that unless there is a good fall ere long the trees will cast many of their fruits. For the third season in succession we are suffering from drought, and the thunder and rain storms which have been prevalent of late have passed by without benefiting us in the least. Among sorts of Apples bearing heavily, the following call for special mention, viz., Juneating, Beauty of Bath, Duchess of Oldenburg,

Kerry Pippin, Hereford and Worcester Pearmain, Golden Pippin in variety, Scarlet, Ross, and Old Nonpareils, London, Ribston, King and Cox's Orange Pippin, Cox's Pomona, Queen, Old and New Northern Greenings, Tower of Glamis, Pott's and Ecklinville Seedlings, Lane's Prince Albert, Annie Elizabeth, Maltster, Lady Heniker, Baumann's Red Reinette, Lord Derby, Stirling Castle, Warner's King, Cellini, Small's Admirable, Blenheim Orange, Warner's King, Bismarck, Lord Clyde, Mère de Ménage and Wellington. Of Pears, Beurré Giffard, Colmar d'Été, Souvenir du Congrès, Gratioli of Jersey, Louise Bonne, Beurré d'Amanlis, Beurré Hardy, Alexandre Lambre, Marie Louise, Doyenné du Comice, Beurré d'Anjou, Thompson's, Beurré d'Arenberg, Glou Moreeau, Beurré Baltet Pere, and Chaumontel are heavy crops. Apricots are a heavy crop, or, I should say, have been, as they are nearly all over. The fruits have been very fine, particularly the New Large Early, and all without exception have ripened to perfection, which fact has enabled their being used for dessert daily for weeks past. Root waterings have not been such a heavy item in their culture as in the two past seasons, while growth has been excellent and clean. All that is now wanted is a fine autumn to mature both wood and buds. Peaches and Nectarines are a good average crop, but much later than usual owing to the cold spring weather. Fly was troublesome in the early stages of growth, but was eventually subdued, since when growth has been satisfactory. Alexander ripened the third week in July, or quite a fortnight later than usual. The fruits were, however, very fine for the variety and of excellent flavour. Royal George, Crimson Galande, Dr. Hogg, Alexandra Noblesse, Raymackers, Magdala, Violette Héative, and Belle-garde are also extremely good, and so are the following Nectarines: Lord Napier, Elruge, Downton, and Humboldt. Dessert Cherries have been plentiful and good, but are now over. Kentish and Morellos are a wonderful crop both on walls and out in the open garden. Black fly was rather persistent in its attacks early in the season. Of bush fruits no better crops could be desired, and the fruits have been fine and good flavoured. Superlative Raspberry is a grand acquisition, the fruits being enormous in size and produced over a long period. Strawberries were naturally later than usual, but they continued a long time in use. The crop was an abnormally heavy one, the individual fruits being large and the flavour good. Royal Sovereign fully sustained its reputation as a first early, and gave great satisfaction. One break of this variety made more leaf growth than it has done in previous seasons, but this I attributed to an overdose of chemical manure, as growth on another break was quite normal. Runners were late in being pushed out; consequently planting will not be performed until the last week in the present month.

With regard to vegetable crops, these though late have been unusually abundant and good. Among Potatoes, Famous out-distanced all others in point of earliness, and left nothing to be desired as regards crop. Other varieties have also turned out well, and the flavour when cooked is excellent. Lifting of second early sorts is going on well and the yield is good. Main-crop and late sorts are, to judge by appearances, taking no harm from the effects of the drought, but if the latter becomes very protracted, a great deal of lifting will have perforce to be done when rain does fall, otherwise the tubers will make second growth. So far there is no trace of the Potato disease, for which we are indebted to the hot, dry weather. Peas have been very abundant, and the same may be said of Broad Beans. French Beans are plentiful, and Scarlet Runners are now yielding well. Both crops, however, demand plenty of attention in the way of watering. There has not been a break in the supply of Cauliflowers since they commenced to turn in at the beginning of June, and autumn Broccoli promise to be very fine. The breadths of winter and spring varieties of the latter look well, as also do Brussels Sprouts and other kinds of Brassica. Celery has required ample supplies

of water to keep it growing, and even with this attention the early plants are not in such a forward condition as usual. When the weather gets cooler it will no doubt soon make up for lost time. Lettuces and Endive are plentiful and good, they enjoying the shade and coolness of a long border under a north wall. Onions have fairly revelled in the hot, dry weather, and I have never had finer bulbs. Turnips on an east border are tender and first-rate when cooked, the crops to succeed these being on a north border. Carrots of the Short Horn type are excellent. The intermediate sorts which I depend on for main crop did not grow away so quickly as usual, and will, it is feared, be rather undersized unless rain falls shortly. Turnip-rooted Beet is fit for use, and is far more palatable than the old roots of the long varieties of last year's growth. Seakale for forcing has made excellent growth, and the crowns promise to be very fine. Marrows require plenty of water to keep them in bearing condition, and ridge Cucumbers the same. As soon as the ground receives a good soaking rain there will be much planting of Coleworts, Cabbages and late Savoys to be performed, as it is labour and time thrown away to do it while the soil is in such a dry, parched state.—A. WARD.

The Abbey Gardens, Ramsey, Hunts.—The fruit crop here is a good average one, Apples, Pears, Plums, Cherries, Apricots and Peaches all carrying good crops, although quite two weeks later than usual. Red, White, and Black Currants are above average. Gooseberries on old bushes are below average, but young cordons are carrying heavy crops of fine fruits. Strawberries are good, Royal Sovereign and Leader being the two best varieties. Walnuts are very heavy crops.

Vegetables have been very good. Potatoes are rather below average; a new variety, a round white named Klondyke, grown and shown in this neighbourhood, promises to be a valuable variety.—F. W. SEABROOK.

NORTHERN.

Nidd Hall Gardens, Ripley.—Strawberries were a good crop, but small through want of rain. All bush fruits are excellent. Apricots are a moderate crop. Apples are very irregular, some trees having a nice crop and many none at all. It is safe to say that they are very much under average. Pears are also a disappointment. The bloom was very abundant, but they did not set owing to the cold and rough winds. Plums are very poor.

Vegetables are good, except the Brassicas, and it was far too dry for them; in fact, Broccoli and Cauliflowers had to be planted over again several times. Peas have been very good, only too short lived.—GEORGE ELLIS.

The Gardens, Naworth Castle, Carlisle.—Owing to the cold spring, garden crops are unusually late. Apples are a heavy crop, Pears almost a failure, while Plums are a long way under the average. Gooseberries, Raspberries, Black and Red Currants are extra good. Strawberries have been a splendid crop and of good quality.

Vegetables on the whole are looking well, spring sown Cabbages now coming in. Several in this neighbourhood have been complaining about their early Cauliflowers going down with grub, though none have been affected in the garden here. Carrots are also bad in places, whole beds having to be cleared out and sown or planted afresh with other crops. The Onion fly has not been so troublesome this year. Timely thinning and frequent dustings with soot and wood ashes, with a watchful eye for any plant that may be affected, go a long way to prevent its destructiveness. Potatoes are lifting well, and so far there is no sign of disease. Peas are cropping heavily and free from mildew.—J. HILSON.

Broughton Hall, Yorks.—The spring was most unfavourable for early bloom; consequently Peaches, Pears, Plums, and dessert Cherries are thin. Peaches were badly attacked with blister, the result of a long spell of wet and cold winds.

Later, the trees have made most free and healthy growth. Apples, Strawberries, and all bush fruits are most abundant. The fine, hot weather came just right for the Strawberry crop, which has been excellent for size and flavour. Royal Sovereign, President, Vicomtesse H. de Thury, Frogmore Late Pine, and Laxton's Latest of All are the kinds that succeed best here.

Vegetables of all kinds are exceptionally good, Peas especially so.—J. RAINBOW.

The Gardens, Appleby Hall, Atherstone.—The crops are very good take them on an average. Apples are very light; we have more Blenheim Orange than any other. Pears are under the average, but fruit fine. Plums heavy crop on the walls; standards and bushes very light. Apricots are few. Strawberries, Raspberries, Gooseberries, Currants are abundant and good. Damsons are a failure.—A. GARRB.

Wortley Hall, Yorkshire.—Small fruits good or fair. Apples, Pears, Plums, and Cherries promised abundantly, but the crops are either under average or a failure owing to the disastrous weather when the trees were in bloom.

Vegetable crops are unusually late. Potatoes a good crop.—J. SIMPSON.

Hornby Castle, Bedale.—Apples are a fair crop here this season, and such kinds as Betty Geeson, Prince Albert, Ecklinville, Lord Suffield, Irish Peach, and Stirling Castle are bearing heavy crops; Warner's King, Dumelow's Seedling, Newton Pippin and Cellini Pippin are very thin. I believe the Apple crop generally in this locality is poor owing to the drought. Pears are also a good crop with me. Souv. de Congrès is fine, also Marie Louise, Pittmaston Duchess, Bergamote d'Esperen, Gansel's Bergamot, and Clapp's Favourite are producing heavy crops. The crop is fairly good in most gardens that I visited in North Yorkshire. Apricots are a fair average crop here, and I think the same may be said generally in this locality. Plums are thin, but on the whole better than last year. There was an abundance of bloom and a fine set, but the long drought has thinned them in most places. Peaches out of doors are a failure with the one exception of Alexander. Currants have produced good crops, and Gooseberries are a heavy crop generally in this district. The Strawberry crop, which promised to be an exceptionally heavy one, suffered very much from the dry, hot season, but Vicomtesse and Royal Sovereign have done remarkably well with me. British Queen is better than I have seen in this district for years.—JAMES NICOL.

Sand Hutton, Yorks.—Apples are plentiful, hardly a tree being fruitless. Pears are, with the exception of a few early sorts, such as Citron des Carmes, Doyenné d'Été, Louise Bonne of Jersey, and a few Williams' Bon Chrétien, a failure. Of Plums, there are a few fruits on wall trees; standards are fruitless. Apricots and Peaches on outside walls are a thin crop; Cherries an average crop. Raspberries, Red and Black Currants, Gooseberries, and Strawberries are abundant, but all have suffered from the long drought.

Vegetables, although a little late, are looking well, but wanting rain.—JAS. FOLKARD.

Abney Hall, Cheadle.—With the exception of some Apple trees that are carrying good crops of fruit, the other orchard trees are almost a failure this year. Small fruits are heavy crops, especially Gooseberries, Black and Red Currants. Strawberries have been very satisfactory crops, too, and well got. In some places in this district Strawberries have been very heavy crops.

Regarding vegetable crops I am able to report satisfactorily also. The season has certainly been a little late, but with few exceptions the crops are all very good. Peas are excellent; so have been Cauliflowers, early Potatoes, and Turnips. Onions have been unusually free from maggot. The two worst items are Carrots and Parsley, that have done badly owing to the dry weather. Celery has suffered, too, somewhat, but after the recent rains no doubt it will grow apace. Winter

stuff, such as sprouts and Autumn Giant Cauliflower, are looking well.—ROBT. MACKELLAR.

Underley Gardens, Kirkby Lonsdale.—The fruit crops around here are disappointing this season. Apples, Pears, Cherries, Plums are scarce. Bush fruits are average except Red Currants, which suffered from bullfinches. Strawberries are very good, especially Royal Sovereign; Empress of India did very well.—W. A. MILLER.

Mulgrave Castle Gardens, Whitby.—The fruit crop here is a very good one, especially small fruits. Black, White and Red Currants are very fine; so are Raspberries and Gooseberries. Situated as we are on the coldest part of the north coast, and elevated 310 feet above the sea-level, everything is therefore very late this summer. Strawberries were later this year than I have known them for eight years. The crop has been good since the rain fell, but a very large quantity suffered from mildew and the drought. Apples and Pears are only a fair crop. Ecklinville Seedling never fails here; the same with King of the Pippins and Mère de Ménage. Plums on the wall are a poor crop, bush trees a moderate crop. Cherries will not do at all here in the bush form; on the walls Morellos do well, but are a poor crop this year; a good crop set, but fell off after they were half swollen.

The vegetable crops in the early part of season did well except Peas, though the second early Peas have done remarkably well. French Beans will be a failure here unless we get warmer weather. Spring-grown Onions are a failure; the heavy rain on May 20 and 21, when 2.84 inches fell, did a lot of damage. Slugs were exceedingly numerous, and made havoc among the Onions, which I have never known them to do before. Potatoes are a very good crop and of a nice size.—JOSEPH CORBETT.

Grimston Park.—All Apple trees were very full of blossom in the spring, but it failed to set well on many kinds. The weather at that time was not at all propitious; still, I do not think the frosts were the only cause of the thin set alluded to. I have fair crops of Lord Suffield, Beauty of Kent, Keswick Codlin, Hawthornden, Warner's King, Lewis's Incomparable, Galloway Pippin, Barnack Beauty, Stirling Castle, Rose Hill, and Grey Leadington. I never saw such an epidemic of American blight as we have this year. Trees that have not hitherto had a vestige of that pest are in some cases smothered with it this year. Now that the foliage has got hardened, so to speak, I am syringing the dwarf bush trees with paraffin mixture, made with two wineglasses of paraffin to two three-gallon cans of soft water. If kept well mixed during the application, I find it checks the pest and does not injure the foliage. Of Apricots I have a full crop. I had to thin them severely on most trees. Since then—in fact, quite recently—quite a large number of fruit has fallen off, but plenty is left for a good crop. Moorpark, St. Ambrose, Hemskirk, Large Early, and Kaisha are my main kinds. Within the past fortnight I have lost several limbs from the mysterious branch-dying, but not to the same extent as in some seasons. As showing how the roots of Apricot trees will come to the surface of the borders in which they are growing, I may here mention that to-day I have been clearing off a three-year-old plantation of Strawberries from our Apricot border. In digging the ground over for planting winter greens, I found the whole of the surface of the border for fully 15 feet from the base of the wall quite a mass of fibrous roots. This is not a new experience, but I thought it worth mentioning. Apricots as a rule do fairly well in our stiff limestone soil. Were I in a position to do so I would confine the roots to a border say two-thirds of the height of the wall they are growing against, and would not crop this border with anything, allowing it to get equally firm all over first, breaking the surface once a year with a fork so as to admit the moisture, natural and artificial, equally all over the surface. Plums are very thin; even that free bearing useful Plum, Victoria, is almost fruitless

this year. I cannot account for this, seeing that the trees bore extra light crops last year. Here and there in our district one comes across a well-fruited tree; otherwise my remarks apply generally to this part. A local Plum called Balls has nice crops in places. It is not by any means a choice kind of Plum, being more or less bitter even when fully ripe. Winesours, which do well on the lime-stone soils in this district, are, like the rest, a partial crop. Of Pears we have about a good half crop. The ones that are fruiting well are Doyenné d'Été, Citron des Carmes, Louise Bonne of Jersey, Summer Franc Real, Beurré d'Amanlis, Urbaniste, Bergamote d'Esperen, Beurré Diel, and Brown Beurré. Morellos are very plentiful, but dessert Cherries are very scarce. The trees seldom bear well with us, especially on walls. Strawberries were very promising at first, being very full of blossom. Unfortunately, fully one half of the flowers at the extremity of the blossom-stems did not swell off at all well. The first opened ones swelled off very well, and the fruit was fine in size. Royal Sovereign, which, in my opinion, is a variety that has come to stay, did very well with me; so also did President, James Veitch, Noble, Jubilee, and a locally raised kind named Newton Seedling. This is a capital kind for preserving, and is later in ripening than the others named. It is an old kind, raised fully thirty years ago by the Rev. Mr. Challoner, then Vicar of Newton Kyme, near here. He once told me its parentage was Keens' Seedling and Black Prince. It certainly favours both these old well-known Strawberries in its habit of growth, &c. Raspberries are a good crop. A variety I have named before, viz., Superlative, still improves on further experience. Like Royal Sovereign Strawberry, it has, in my opinion, come to stay with us. We have good crops of Currants. Carter's Prolific is especially good; some trees of this variety planted three years are simply smothered over with fruit all the length of the branches. There is a good crop of Walnuts, but Hazel nuts are not very plentiful. Peaches and Nectarines are a thin crop, but the trees are healthy and fairly free from insect pests. Should we have a fairly dry, warm autumn no doubt there will be good crops next year. I never protect the Peach, Nectarine, and Apricot trees with anything but a doubled herring net, which is used later in the season for protecting Strawberries from blackbirds and thrushes, which this year have been very troublesome.—H. J. CLAYTON.

GARDEN FLORA.

PLATE 1188.

CLERODENDRON SPLENDENS.

(WITH A COLOURED PLATE.*)

THE true plant of this name is a very handsome stove climber which flowers freely in early spring and onwards through the summer, producing elegant clusters, sometimes 6 inches through, of brilliant crimson flowers. There is also a spurious *C. splendens* in cultivation, which is, I believe, a hybrid of garden origin, between the true *C. splendens* and *C. Thompsonia*, and which is much inferior to the plant here figured, the flowers being dull in colour. Grown in a moist stove near the roof-glass, *C. splendens* forms a loose climber with shoots from 1 foot to 3 feet long, clothed with glossy dark green oblong leaves. It is a much less vigorous grower than the popular *C. Thompsonia*; indeed, by stopping the shoots it might be made to form a bushy shrub.

C. splendens was introduced from Sierra Leone in 1840 by the collector Whitfield, and

* DRAWN FOR THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Gouart.

flowered in Mr. Knight's nursery in the King's Road, Chelsea. Lindley published a figure of it—a poor one—in his *Botanical Register* in 1842, and described it as one of the handsomest stove plants then in cultivation. It has not, however, found general favour, although it deserves to-day all that Lindley said of it fifty years ago. It is essentially a tropical plant, and would grow indifferently well in the temperature which satisfies its near ally, *C. Thompsoniæ*.

The genus *Clerodendron* consists of about seventy species, some of which are almost trees, others being woody climbers, and others herbaceous perennials. A selection of the best of those grown would be *C. Thompsoniæ* and *C. splendens* for the stove, *C. fallax* and *C. fragrans* for the greenhouse, and *C. trichotomum* and *C. foetidum* for sheltered positions out of doors. W. W.

THE WEEK'S WORK.

KITCHEN GARDEN.

GENERAL WORK.—Many crops at this time will need close attention owing to the prolonged heat and drought. The Cauliflower crop has been an uncertain one, many of the varieties turning in before their time, and to meet deficiencies later on, it will be well to give small plants encouragement in the way of food to help them to term heads more quickly. I have early this month been obliged to mulch plants freely to keep them going, for with a dry, light soil it is not an easy matter to get the best vegetables in such a summer as we have just experienced. The mulch must conserve the moisture given. I find spent Mushroom manure excellent, and it should be dug in when the crop is cleared. Another point often overlooked in such soils is the advantage of digging in superfluous green crops. I do not clear away such crops as salads and Spinach, but these if well covered give the land much moisture, as the refuse decays readily.

THE LATE PEA CROP will well repay food in many gardens. I fear there will be a poor return from what may be termed the last supply, as with me it has been a difficult matter to keep the plants healthy, thrips and red spider having been so prevalent this season. My worst failures are with the taller growers, such as *No Plus Ultra*, which will be very poor. On the other hand, in heavier soils there will be better results, and now the cultivator by feeding will get a better supply. To check mildew on late varieties I would advise a dressing of Bentley's mildew specific, or, failing this, some soft soap and sulphur made into a wash will get rid of the pest. This should be applied in the evening, well covering all portions of the haulm.

DWARF BEANS will well repay the liberal supplies of moisture they delight in. These should be given late in the day, as they check the spread of spider, which badly attacks these plants. Crops of all kinds, such as old Cabbage, salads, and other quick growers, should be frequently hoed between, as it is essential to keep the surface soil in a sweet condition. Vacant land if at all troubled with slugs, wireworm or other pests should get a liberal dressing of lime, which if placed on the surface before digging in will be pulverised and in better condition.

CELERY, like all other vegetable crops of a succulent nature, will need copious supplies of moisture, and the present is the time to feed it. I have always found that if Celery is given huge masses of rank manure at planting and then left to chance, it is frequently tough and a goodly number of the plants run. Though the rainfall at this season may be sufficient for small-growing plants, it is not so for Celery, as the ample leafage throws off the moisture, only a very small quan-

tity reaching the roots. I find it best to flood the trenches at least once a week from July to the end of September, for by so doing there is not one plant in a hundred that bolts, and the quality is good. Few plants better repay for food given when in active growth, and I have great faith in soot and salt, which, if applied previous to watering, will be most beneficial. Soot imparts a healthy hue to the foliage, and, what is better, it keeps the dreaded maggot at bay. At this time of year this pest is most troublesome, but if soot is used freely when the leaves are moist, it will prevent its spreading. With plants badly attacked it may be necessary to cut away the bad portions of the leaf, as the grub, being encased between the outer and inner lining of the leaf, is difficult to get at. As regards other foods for these plants, if liquid manure from stables can be had, there is nothing better, and previous to giving other foods, such as guano, fish manure or other fertilisers, I would advise the removal of any useless leafage from the base of the plants. This will admit of the manure being given to better advantage and going to the roots. Early plants may now have a portion of soil for blanching, but it must be given after a liberal watering, as to blanch with the roots at all dry will give heads of poor quality. I am not in favour of too early earthing up. It is far better to give just enough to blanch a row or two for present use, leaving others as long as possible to perfect their growth. If earthing up is deferred as long as possible it allows the leafage to get well developed and hardened. The plants may be given moisture more readily, and food also, as long as growth is active. I am of opinion that many failures occur through premature blanching. This is the cause of the hearts rotting in the winter, as the growth of the plant is crippled in its early stages, and the small foliage being the weaker it cannot expand, but decays. When giving soil I usually place from 3 inches to 4 inches at a time, for more retards the growth. The soil given should be in a moist condition. Another moulding up may follow in a couple of weeks' time, and the same routine be observed till the plants are blanched to the length desired. Previous to the earthing up it will be necessary for the plants to be given a tie or support to keep the leaves erect and the soil out of the axils of the leaves. These ties must not prevent the swelling, but should be of a very light material and very loose. Late-planted Celery should get liberal supplies of moisture, and should be left as long as possible before giving fresh soil.

CABBAGE.—Those who prepare a special spot for the spring Cabbage will ere this have got the land in condition for the plants, but if not, no delay should take place in getting the soil ready. Land that is at all infested with grub should be thoroughly dressed with lime to get clean growth. I use gaslime freely, and find by so doing I get good results. Of course it would not be well to give heavy dressings of gaslime and plant tender seedlings at the same time. I mentioned previously the advantages of doing the work some time in advance of planting if the place could be spared for the spring Cabbage, and the lime should be well broken up and pulverised by exposure on the surface for a few days. I am not greatly in favour of placing large quantities of animal manures in land for the Cabbage, as though the plant needs ample food when in active growth, from October to the end of February growth is not large and the rank food at the start fosters a soft growth, whereas a sturdy one is needed to stand our variable winters. It is an easy matter to feed plants just as growth is active, and this is more beneficial than when the plant is put out in the early autumn. In my case Cabbage follows the spring Onions, and, the soil being very light, it is not dug or manured. It was treated liberally for the Onion crop, and the surface-dressings during growth will now benefit the Cabbage. I draw drills previous to planting, as these allow of watering being done more readily, and the land

being hard trodden is just in condition for the plants. When such kinds as *Ellam's*—and this is one of the best—are planted, they need less space than larger kinds, as the hearts are usually cut in a young state. There is no need to give more space than 18 inches between the rows, and this allows of better working between hoeing and feeding in the spring. I am not in favour of planting the whole spring supply at one time, as it may happen the earliest plantings are the first to suffer in severe weather. I make three—one now, another a month later, and one at the end of February. For this last date the seedlings are pricked off into rows late in October, which give us material for patching or filling up losses, and they make a good succession to the earliest plantings. In planting it is well to make each plant as firm as possible with the dibber. The medium-sized plants are the best for the spring supply, and by drawing for the September planting it will give those left in the beds more room to develop. The seedlings this summer have had a hard time owing to heat and drought, and in some soils they may be affected by club, which must be guarded against and the injured portion cut away, and the roots dipped in an equal mixture of soot, lime, and clay made into a puddle, so that it elings to the roots. On light soils I advise deep planting, and with drills this still holds good, as the stem of the plant is the portion injured in severe weather. I have this season found a great many of the Brassicas are blind, and this should be carefully noted when drawing the plants, and, should the weather be dry, it is advisable to water the seed-beds and the drills the evening before planting. This will make the work more easy and it can be finished sooner than when the soil crumbles and fills in the space made by the dibber. S. M.

HARDY FRUIT.

THE FRUIT ROOM.—The word "room" is more often used than otherwise, but in many cases it would prove more satisfactory if it were a cellar instead. The fault of many fruit rooms is their absorbent properties. They may be constructed in an elaborate manner, but this is no guarantee of their suitability for the keeping of fruit in good condition. The fruit store in order to be effectual should be cool and not too dry. My own idea of one is that of a cellar rather than anything else. Let it be entirely below ground, entered at both ends if desirable; probably this would be the better plan. With an even arrangement of the ventilation through air bricks, the same being controlled at each point both at the inlet and exit, there will not be any undue amount of moisture. The walls of such a place will not absorb much, if any, moisture from the interior, it is true, nor should they do so, but from the exterior they will do so where in contact with the earth. In such a place as this the prevalence of shrivelling would be very remote provided all the fruit was well matured when it was gathered. The fault of many fruit rooms is that of excessive ventilation, this being provided for in unequal proportions. Others are unavoidably too warm from various causes. In my own case this was once caused by its being constructed over the living-room of the bothies, with the chimney also acting in unison. The result was that the fruit ripened in advance, or it shrivelled. The management of the fruit store (as it should be called) needs careful attention. For a time after the fruit is put away rather more ventilation is needed than afterwards, but do not allow this so much by day when warm as by night when cooler. Never store specked or otherwise doubtful fruits with those of sound quality. Avoid also any overcrowding in storing—for the first few weeks at least. Shutters for the windows, to exclude light, are desirable. These also act in keeping out frost later on, whilst at the present time quite the reverse is the case. Look well to the cleanliness of the walls and of the shelves, whitewashing the former and cleaning the latter with carbolic soft soap and water.

FRUIT GATHERING.—Hitherto it has chiefly been the early and non-keeping fruits which have been taken in, but now the earlier of the keeping kinds of Apples will be quite fit to gather. Before writing this I had gathered Yorkshire Beauty, Ecklinville, Frogmore Prolific and Domino, whilst with the very warm and dry weather we must be prepared for other and later kinds to be fit rather sooner than usual. Avoid overcrowding the fruit by putting it into large or deep baskets, using also every other precaution to prevent any injury by bruising. If the fruits be specially good examples and they do not part readily from the branch, it will pay to leave them a few days longer. In dealing with Pears that do not keep long after gathering, it is better to gather at short intervals, afterwards keeping a portion of these gatherings in varied temperatures. If such a Pear as Williams' Bon Chrétien now in season be gathered all at once, it will ripen more or less in the same way, hence waste will ensue. In dealing with a heavy crop of Plums of any particular kind, it is better to treat the crop in the same way. Unless anyone has given it a trial, he will be surprised to find how long cooking Plums will keep in good condition after gathering when gathered in a firm or partially green state. The flavour, it is admitted, may not be quite so good, but the prolongation of the season is an important matter. Those who are fortunate enough to have a heavy crop of those fine late Plums Grand Duke and Monarch, will do well to treat a portion of it in this way. Watch carefully at the same time for any change in the weather, and bear in mind that Plums do not keep well after such changes. Dessert Plums had better be gone over the same as Peaches and Nectarines at least three times a week (every day where the crop is heavy), taking the ripest fruits whilst still tolerably firm if for home use, but firmer or about three or four days prior to being fully ripe if for travelling. Figs must also be treated in this way, otherwise they will not travel so well at this season of the year. Gather all of these tender fruits in the cool of the day—the earlier the better so long as not damp. I prefer to use Grape scissors for taking dessert Plums for fear of injury to the bloom as well as to secure the stalk, without which these fruits do not look nearly so well.

THE CUT-LEAVED BRAMBLE.—It has occurred to me that the cut-leaved Bramble is worthy of a special note. Just now the canes are completely loaded with their heavy crops of large fruits, a dish of which may be gathered in a few minutes without moving a step. These are used both for dessert at the breakfast table and for cooking. Ripening as they do in succession, the season will be considerably prolonged, the first fruits being only just gathered. This Bramble is well worthy of extended culture in any garden, but more especially in places where the wild Bramble cannot be safely guaranteed. It affords a most welcome change, whilst it is a capital substitute for the autumn-fruiting Raspberries where these are unreliable. My plants are growing at the foot of a low wall facing north and north-east; hence the roots are cool and moist, two desirable attributes to success, whilst it also facilitates the object in view, viz., that of retarding the crop as long as possible. Compared with the Wilson Junior, the cut-leaved variety is infinitely better both in flavour and cropping qualities, while it is also later in ripening.

AUTUMN-FRUITING RASPBERRIES.—These are later than usual this year, owing no doubt to the drought in my case, as their position is not so good. These evidently require a similarly cool soil as the Brambles, and so does the Wineberry, which so far has not been made to do a very great service.

THE DROUGHT.—As the phenomenally dry weather still continues, let watering be one of the chief items. Do not neglect newly-planted trees on any account. These are almost sure to be the first to suffer, not only those planted last season, but for two or three seasons past. Trees from which the fruit has been gathered should not be

neglected. These have been severely taxed; hence their fibrous roots will be suffering. Water to these now is the very essence of their existence, bearing in mind the bud-development that has to be completed for another season. Do not be led away by the sere or yellow appearance of the leaves and assume that this is a good sign of maturity. Quite the reverse is the case thus early in the autumn; it may lead to adventitious flowering another spring, but this is not desirable, as all of us should know by practical experience. HORTUS.

KITCHEN GARDEN.

FEEDING ASPARAGUS.

EXPERIENCE is the best tutor in all things relating to the management of a garden, but the experience most desirable is that which has a certain amount of scientific knowledge to guide it. In the cultivation of Asparagus, it is surprising to see how well it succeeds on some soils with little effort or trouble taken to promote its growth, while on others it is a hard matter to get it to exist. At Oakmere Hall, Northwich, in the Delemere Forest—the centre of salt in Cheshire—it thrives amazingly in the red sandy formation with only a top-dressing of stable manure. Some beds I saw last spring were a mass of young, strong, succulent growths—the best evidence of suitable soil and management. Mr. Brunton, Captain Higson's able gardener, informed me that he practised the old method of culture by simply covering the beds in early winter with farmyard manure, and removed it in spring, and that nothing more seemed to be needed. Facts verified his conclusions, and proved that the medium he had to deal with was a naturally rich one, for the soluble fertilising constituents of the manure carried into the soil of the beds by the winter's rain could not equal the amount abstracted from them during the growing season. This sandy soil, too, was a guarantee of good drainage, and that the chance of crowns rotting was reduced to a minimum. Having myself to deal for years with a very much heavier formation than the one at Oakmere Hall, I found the method of culture adopted there detrimental in my case. In fact, in practising it the crowns diminished in numbers and the growths grew smaller year after year. This undesirable result led me to devise other means of supplying the waste of plant food material to the soil than the one described, which was accomplished in this way. Whenever growth ceased, the beds were mown with a scythe, all the stems collected and burned on an adjoining piece of land, and the ashes returned to the beds. All weeds were cleared off, and a heavy dressing of basic slag, kainit, and a fair amount of farmyard liquid manure, neat, was then put on. Towards the end of the year 3 ozs. of sulphate of ammonia was applied to the square yard, and about half that quantity of kainit again in spring, immediately before growth started. At the end of the year following this treatment there were visible signs of improved vitality, which were maintained till at the third year the growths were all that could be desired. Although the land was heavy, yet it was well drained, resting on a bed of gravel 2 feet below the surface. Had it been a clay sub-soil I certainly would not have used the liquid manure, as its tendency to promote organic acids in badly drained, heavy land would have been a barrier to healthy growth. As it was, an occasional dusting with quicklime was essential to the sweetening of the soil.

I may also add that under this system of feeding Asparagus more labour is entailed in its cultivation than under the older one, as the potash and phosphorus used as top-dressing do not readily go well into the land. There is an affinity between them and the soil, and they are consequently most abundant near the surface. Grass or any other shallow-rooting weed getting a hold of such a compost grows apace and arrives early

at the flowering and fruiting stages, which stages these ingredients foster, necessitating frequent attention to keep them under. It is imperative, however, that these weeds be kept down as much for the tidy appearance, which should dominate the whole garden, as for the rich manurial constituents they would deprive the Asparagus of. Rather heavy, but well drained land treated in the foregoing manner and kept free from weeds will, under ordinary circumstances, support the growth of strong succulent Asparagus, and be one of the most remunerative as well as the most useful quarters of the kitchen garden.

J. RIDDELL.

Globe Beets.—Although these round-rooted Beets are not popular in the markets, it seems difficult to assume that very soon so fine a stock as the blood-red one just awarded a merit certificate will not presently make its way in public estimation. The roots are unusually deep, in fact as deep as broad, and therefore practically round, also very handsome; the flesh is very solid and of a fine grain, in colour rich crimson-red. It could not be better in any variety. This stock shows how great is the advance made since the introduction of the Egyptian Round, the flesh of which was alternately red and white. The stock is so good that the selector is entitled to high praise. Of course, there are other good stocks in commerce, but none seem to show greater depth of root, and therefore more flesh, than this one.—A. D.

Autumn-sown Onions.—Four of the stocks of Onions grown during the winter and summer at Chiswick and presented at the Drill Hall on the 6th obtained awards of merit. Although not new varieties, those of Banbury Cross, Nuneham Park and Rousham Park Hero, flattish round, greatly resembled each other, but they are regarded in the trade as distinct. The stock of Wroxton was quite oval and distinct, and although the bulbs did not seem so large, they were very solid and heavy. No doubt the best of the ordinary spring-sown stocks are those which give oval or deep round bulbs, as they are less liable to split. The autumn-sown bulbs were, as a rule, three times heavier than were the best bulbs of the spring sowings. It is determined to submit the autumn-sown bulbs to the test of keeping, and those features will be reported upon.—A. D.

Tomatoes planted out.—There is no check to the demand for Tomatoes, and at the present rate of progress they look like supplanting nearly all the other crops that are grown under glass, for the simple reason that everyone is using them. Although we find Tomatoes planted in houses of the most approved fashion, as well as in houses that only a few years ago were devoted to Vines or Peaches, still the demand is fully equal to, if not in advance of, the supply, and we may confidently expect this to go on for some time, or at least until growers are able to fully realise that they can hardly overstock the market with really good Tomatoes. When I speak of good ones, I do not think it is possible to raise new sorts of much greater merit than we already possess, for I consider that we have varieties enough, as near as it is possible to get them to perfection. When one has decided which variety suits him best, there is nothing gained by increasing the number. I have Chemin Rouge, Perfection, Ham Green, Nimrod and others all growing together, but one sort would do just as well, for no one cares for anything but the smooth-skinned bright scarlet kinds. If the fruits are of medium size, say four or five to the pound, they are much preferred to those that are nearly one pound each. I grow them for earliest crop in pots about 12 inches diameter, for successional crops in boxes, wherever any space can be made under glass, or even outside, where the reflected heat from the glasshouses helps to forward them, but in no case do they produce such a weight of crop or keep on swelling up the top fruits so well as when planted out in a good deep border of soil, similar to a Vine border, where the roots can ramble far and wide.

No crop that I have ever grown exhausts the soil like Tomatoes: in fact, one needs travelling green-houses for them so as to give them fresh fields and pastures new every year to get the best results.—*J. GROOM, Gosport.*

POTATOES.

EARLY Potatoes will on our rather light soil be this year a considerably better crop than the later varieties, and the cause is not far to seek. The former had done their work before feeling the effects of the continued drought, and turn out fine large tubers quite free from disease. The later sorts, on the other hand, were checked in their growth. They run very small, the skin is nearly set, and rain now would mean growing out rather than a swelling of the tuber. Various opinions were expressed some time back as to the relative merits of early and late planting on this soil. I should certainly prefer the former. It is better to risk getting a bit of the haulm frost-nipped if one can ripen the crop and lift before the advent of autumn rains. The introduction of large early varieties, of excellent quality—varieties I mean that if planted with the Ashleaf can be lifted at the same time—was a great boon, especially when it is considered that the majority are excellent keepers. A sort known as Holborn Abundance, grown now some ten or twelve years, still verifies the exceedingly favourable impression formed at the first trial. It has the reputation of being rather coarse in places, but I think this is a matter of suitable soil and careful selection. I have always saved my own seed, and now after twelve years the crops are as good as in the first season. Some of the tubers are of extra size, but they are also of excellent quality, and early in the season are, when well cooked, literally balls of flour. It is ready to dig with the Ashleaf, and is a heavy cropper, averaging in the majority of seasons ten tons per acre. I have to-day (August 22) started lifting another special favourite—Windsor Castle. The crop is very heavy, perfectly free from disease, and very few small tubers. The fact that this Potato will keep out with the latest and yet is ready to lift early in the season should always secure it a prominent place. Personally, I shall rely almost solely another season on the two already named. There is a qualifying statement here because a sort on trial for the first time—Ninety-fold—has turned out so remarkably well that it must be planted again, and to a larger extent. The soil is as a rule about right for Potatoes; if there is a sign of heaviness where planting is contemplated I work in a heavy dressing some 4 inches thick from a heap composed of vegetable refuse, leaves, short grass, and a little manure, and, as the ground is deeply dug, this is well worked into the bottom of each trench. *E. BURRELL.*

Cucumbers failing (S. W. P.).—Your complaint respecting the fruits of your Cucumber plant dying off prematurely is a very common one, and is doubtless due to inferior soil and to lack of needful warmth. Possibly your soil may contain too much iron, or it may be too light and gritty, as it came from the roadside—not at all the best place to get good Cucumber loam. Before using any other for Cucumbers, mix with it some soot, and a little stiff clay, well exposed to frost all the winter to sweeten, will be very helpful. Complaints of this nature usually come from amateur growers, who as a rule give their plants far too much root room and a soil that is not sufficiently sweet or solid. Can you not get fresh, sweet turfy loam from a fresh position another year? You say you have ample heat. The temperature should range from 65° at night to 80° in the day.

Jerusalem Artichoke disease.—Those who have, like myself, been troubled with the virulent fungoid disease which attacks the Jerusalem Artichoke, especially the white variety, will do well to examine their stock at once and pull out bodily

all affected plants. Though all I have planted this year came to me in the spring from stocks which have hitherto shown no disease, and were planted in quite a different part of the garden to that occupied by last year's diseased stock, I have already found a dozen or more affected plants, which I have destroyed in the hope of stamping out the disease. These were all of the white form, which confirms my experience last year that this is peculiarly liable to take the disease. Both purple and white are again occupying one plot. The first sign of disease appears in the stems, which turn black about a foot from the ground and then become covered with mildew spots; the disease then proceeds downwards, and soon turns the whole of the small tubers and fibrous roots into a rotten mass. Until it has made some progress the upper portion of the plant is not affected and keeps on growing, so that it takes more than a casual glance to detect its presence. The virulent nature of this fungoid disease, which is said to be a form of *Peziza sclerotiorum*, is shown in the fact that the ground occupied by the diseased Artichokes last year has been planted this summer with Buda Kales, very few of which have escaped from an attack, though they appear, so far, to be able to resist it sufficiently to prevent their being killed outright.—*J. C. TALLACK.*

NOTES ON TOMATOES.

THROUGH the kindness of a friend, a large market grower in Jersey, I have this season been enabled to conduct a trial on a small scale of different kinds of Tomatoes, all raised from seed supplied by him. The object of doing so was to ascertain which were the best among the number grown, both as regards earliness, cropping powers, size, colour, and last, but not least, quality and flavour. One sort belongs to the corrugated section, the remainder being smooth and round, and more resemble the Perfection type. Again, one sort has a salmon-red skin. The others are red, varying from bright red to crimson. As regards size, there is little to choose between them, the smallest attaining to fair proportions and quite large enough for general use. As regards cropping capabilities they are all very prolific, but the sort which will be presently mentioned first on the list takes the palm in this direction. The plants have been grown in shallow boxes trained to single stems, and all received the same care and attention in every detail, so that the trial should be an impartial one. The first sort is one named—

EXTRA ROUND SEEDLING.—This is a dwarf, short-jointed kind, producing a truss of flowers at every joint, and it is a very free setter. The fruits are large, round, smooth, bright red, solid, and of fine flavour. It also possesses the additional merit of being very early, as it ripened its fruit quite three weeks in advance of the others. This is a most promising sort, and one that I shall grow largely another season for early supply, as its adaptability both for market or private gardens is very pronounced. The next is

LORENZ'S FORERUNNER.—This is a taller grower than the preceding, but it is a good cropper. The fruits are large, juicy, firm, and good-flavoured. The only objection to it in the eyes of many growers is the colour, which is salmon-red. This would tell against it as a market variety, otherwise it is satisfactory in every respect.

HACKWOOD PARK is a splendid Tomato, but lacks the earliness and dwarf habit of the first named sort. As a heavy cropper it ranks next to it, however, and the large bright red fruits are excellent in every way.

SUTTON'S MAIN-CROP.—This is very distinct both in fruit and foliage, and is the one I am least impressed with on account of the fruit being so corrugated. In other particulars, as regards crop, size of fruit, and flavour, it leaves nothing to be desired, and it is just one of those Tomatoes which many English cooks prefer for saucing.

FIDLER'S CRIMSON QUEEN.—This is marked as now, and was quite unknown to me. It is an extra large-fruited Tomato, smooth and round, and rather flattened. As its name denotes, it is crimson in colour, and the flesh is exceedingly firm, juicy, and first-rate in flavour. It is a capital kind both for market and private use.

Other sorts raised at the same time were Industry, Chemin Rouge, and Polegate, or Improved Hackwood Park, but, the plants being weakly from the start and lacking constitution, they were not included in the trial. Ham Green, Sensation, and Freedom I also received, but these had to be excluded owing to their arriving so late in the season. Out of the five sorts tried, Extra Early Round stands at the head of the list, as from every point of view it is a model Tomato. As an early sort I know of no kind exactly like it. I class Hackwood Park next to it, and I take this opportunity of saying that I can distinguish but little, if any, difference between it and the variety grown under that name in this country. Fidler's Crimson Queen comes next, then Lorenz's Forerunner, with both of which I was previously unacquainted. They are, however, quite distinct, the former in appearance being somewhat after the style of Polegate, but rather more flattened. Sutton's Main-crop would be a good sort to grow where the shape of the fruit is a matter of secondary importance, and it possesses a very hardy constitution. *A. W.*

ROSE GARDEN.

ROSE CAPTAIN CHRISTY FOR MASSING.

THIS splendid Rose is often condemned because its flowers lack fragrance. Although one deplores this fact, there are few Roses really more useful for effective garden decoration. The flowers must become perfectly expanded ere the real beauty of the variety is displayed, but when they are thus developed they are magnificent. The colour is a delicate flesh-pink, edged with silvery white, the expanded flowers of a much deeper hue. As a pink variety for autumnal display it is probably unsurpassed by any other variety, for even Caroline Testout and La France, two superb Roses, have a bad habit of hanging their head, but the flowers of the variety under notice, being upon good erect stems and having a short flower-stalk, are displayed to the best advantage. In the summer, upon very strong shoots, the flowers are oftentimes malformed, which shows that a less vigorous constitution of the plant is preferable. This would be ensured by leaving the growths rather long at pruning time. It is a Rose that will not do upon the Manetti, and is not always a success upon the Brier cutting, but upon the seedling Brier, with its long roots, it is perfectly happy. This season has clearly shown the value of this stock for its deep-rooting propensity. Roses upon it, especially the above and the glorious Teas and Hybrid Teas, are just now throwing up the welcome red shoots from the base that betoken, weather permitting, a splendid late autumn display. I cannot imagine how anyone can doubt the Hybrid Tea nature of Captain Christy, for its exquisite bronzy foliage, of a rich Tea-like colour in spring, is ample evidence of the fact. I do not care much for this Rose grown as a standard, for it is not spreading enough in habit as a standard Rose should be. Probably this is because too much pruning is adopted. I came across a half-standard of this variety in May of this year that was to me a revelation. It was growing in a neglected garden and had not been touched with a knife for three years. Were it not for the ruby foliage I should not have known the variety, for it had a wonderful head and at that time the buds were almost ready to unfold. It was not the climbing form, for it was flowering too freely and on shorter growths than this excellent sport. I am certain that if large heads are desired upon standards they should be less rigorously pruned, even if such

moderate growers as Captain Christy and others are concerned.
PHILOMEL.

Remedy for mildew on Roses.—As for the disease you speak of as attacking your Roses, there are remedies in existence which should be able to cure it. First, there is the Bouillie Bordelaise, composed of the following: Sulphate of copper, 4·4 lbs.; ammoniac, 1·76 pint; water, 22 gals. Dissolve the sulphate in the water, and apply with the aid of a syringe or a pulverisator, moving well about, and the morning is the best time. This remedy ought to have a good effect, especially if repeated two or three times and adopted betimes. I have found also that another called "Soufre Babiaux" gives good results. This also contains sulphate, and if you wish I can tell you where to get it. If you already know these two remedies, there are others I could tell you of, but in my opinion those I have mentioned are the best.—S.

Rose Caroline Kuster.—This Rose is described in many lists as a Noisette, and it is unquestionably a hybrid of this class, having very large corymbs of blossom. But it may be considered really a Tea Rose, and is usually exhibited as such. It has many points in common with Marie van Houtte. For the novice it is an excellent kind, hardy, and amenable to almost any treatment. Let it be sparsely pruned and it will make a capital semi-climber, yielding large quantities of its globular, pale yellow flowers. On the other hand, prune it hard, and fine exhibition blossoms may be produced if shoots are well thinned of the side growths and the numerous buds reduced. As a standard, a very graceful head is formed if the plant's natural habit be studied and the growths merely tipped in the spring.

Rose Charles Lefebvre.

—This is the best of all dark Roses, and is also one of the most reliable. Its flowers are very handsome in shape. In colour it leaves nothing to be desired, being of a rich velvety crimson, shaded with blackish maroon. There are darker Roses—for instance, Abel Carrière, Jean Liabaud, and others—but they all fall short of the superior form and grand free-flowering autumnal qualities of Charles Lefebvre. It grows well and is a true I.P. in foliage and stiff, strong growths. Amateurs would do well to plant this Rose extensively, and I am certain it will give them far more satisfaction than varieties so often seen splendid at exhibitions, but never elsewhere. Charles Lefebvre yields plenty of seed, and many kinds have been produced from it, but none approach it in size or quality, which to me proves the need of cross-fertilising. Its best production has been a sport named Sir Rowland Hill. This has equalled the expectations of those who saw it put up and secure the gold medal of the National Rose Society. It is fairly constant, but now and then will revert to its parent. The colour is a most wondrous shade of plum, or rather the purple of a Black Hamburg Grape. Many object to this colour in Roses, but it is distinct, and therefore, in my opinion, admissible. Paul Jamain and Marguerite Brassac are none other than synonyms of the Rose under notice. A climbing form appeared, but this also turned out to be nothing but the original kind. When not required for show purposes I should grow this superb Rose in pillar form, which would allow its strong growths to be left longer, and consequently a larger number of its fragrant blossoms would be given.—P.

THE ROCK GARDEN AT THE MANOR HOUSE, DAWLISH.

ABOUT two years ago I constructed a rock garden at the Manor House, Dawlish, a portion of which forms the subject of the accompanying illustration. Although this illustrated portion forms a kind of forerunner to larger and bolder work containing caves, a waterfall, pond, &c., it forms, nevertheless, a complete little rock-bed in itself. The bed measures scarcely more than a dozen feet or 15 feet across, but its effect is a pleasing one from the fact that it appears to crop up naturally from the ground in the most simple manner. Artificial rock-work never looks so natural as when the stones seem to rise from a carpet of greenery. If this carpet is studded with flowers, they will give, of course, an additional charm to the scene. In every rock garden a stone whose bottom edge can be clearly seen will always look what it is, viz., a detached stone, but directly the bottom edge is hidden from view the same stone will look like a portion of massive rock

(Helianthemums), and a host of other good things. As already mentioned, the little rock-bed is the forerunner of bolder work, from which it is separated by an irregular grass path connected with an ordinary gravel path leading to the rock garden proper. Here a stiff fountain basin was transformed into an irregular pond among rocks, and the water is now a picture of plant life, being studded with *Nymphaea Laydekeri rosea* and other aquatic gems, while Irises, Spiræas, and other water-loving plants adorn the margin. Passing over a stepping-stone bridge the visitor finds himself before a Fern-lined cave, from which descends a little waterfall. Above the cave *Pesmodium penduliflorum*, Veronics, alpine Rhododendrons, and other shrubs make a fitting background to the picture, while below and nearer the water *Dryas octopetala*, *Dryas Drummondii*, *Dianthus alpinus*, Gentians, Primulas, and other good things abound. Some rocks were specially constructed for the choicest and smallest gems of the mountains. At the further end of the rock garden and beneath the

Portion of rock garden at the Manor House, Dawlish. Constructed by Messrs. R. Veitch and Son, Exeter. From a photograph by Mr. F. W. Meyer.

pushed through from below and apparently continued below the surface of the ground to an indefinite extent.

In the little rock-bed here illustrated the carpets of plants through which the stones protrude consist chiefly of *Lithospermum prostratum*, which, with its bright blue flowers, looks most cheerful, as do also masses of the bright pink *Acantholimon glumaceum* and the Cheddar Pink (*Dianthus cæsius*). *Armeria balearica* covers ground and stones alike, and its pretty white flowers are most abundantly produced. *Sedum album* and *Sedum corsicum*, together with the Cobweb House-leek and a number of Saxifrages, are not only charming when in bloom, but form a capital evergreen carpet refreshing to look upon in winter. The Thrift shown in the illustration is the large-flowering variety, *Armeria cephalotes alba*, by the side of which *Heuchera sanguinea* rears its numerous spikes of coral-red flowers contrasted against some dwarf blue Campanulas and the tall flowers of the orange-red *Linaria dalmatica*, a number of Rock Roses

shade of trees is a cave furnished with seats, from which an excellent view of the whole rock garden can be obtained. F. W. MEYER.

Elmside, Exeter.

Pompon Dahlias.—Whilst the taste for the huge-flowered show and fancy Dahlias is limited chiefly to exhibitors of these flowers, a much wider taste is displayed in favour of the pompons, which are really miniature reproductions of the large ones, and have in many respects much more pleasing hues. Of course, they are very solid, rotund flowers, but, being relatively small and borne on the plants well above the foliage in great profusion, they are useful for furnishing cut flowers, and for that reason have many admirers. They are the very opposite of the quaint Cactus varieties, without doubt the most popular, but the pompons are much the most floriferous. A first-class selection of these taken from recent leading stands is—Whites: Snowflake and Lady Blanche. Creamy white: Mary Kirk. Primrose, shaded buff: Marion. Yellows: Orpheus and Emily Hopper. Yellow, tipped red: Sunny Daybreak. White, heavily tipped deep red:

Rosebud. Lilac-mauve: Lillian. Rosy lilac: Nerissa. Creamy lilac: Ganymede. Orange-red: Phoebe. Chestnut-red: Adrienne. Scarlet: Ernest Harper. Deep scarlet: Bacehus. Crimson: Arthur West. Maroon: Douglas. Very heavy shaded maroon-crimson on white: Dr. Jim; and soft puce: E. J. Junker. This is a first-rate selection of nineteen varieties, which all wishing to have a good collection from which to select twelve for exhibition in bunches should grow, because they are of the very best. Pompon Dahlias need no coarse or rich culture: they need deeply-worked soil, plenty of water, to be well mulched, and occasionally thinned, but not more than moderate manuring, or otherwise the blooms may come large and coarse. Medium-sized flowers are much the prettiest and most liked now by judges at Dahlia shows.—A. D.

ORCHARD AND FRUIT GARDEN.

FRUITS FOR NORTH WALLS AND BORDERS.

THERE is nothing more creditable to a gardener than a garden filled with good healthy plants, where order is displayed at every turn. On the other hand, nothing detracts more from a gardener's reputation than space neglected which might be utilised to serve a useful purpose. In most gardens where any neglect of this kind is apparent, it is almost invariably manifested by uncultivated north borders and bare north walls. Sometimes, perhaps, the soil might not be all that is desired, yet in most cases a very little labour and intelligence would secure the essential conditions. I have seen north walls covered with Morello Cherries, Gooseberries, Currants, and Raspberries. Of course, the Raspberries were grown against low walls. There are some varieties of Plums which ought to succeed on north walls, too, under good management. Seeing that we have a selection of fruits which will succeed with a northern aspect and which are suited to different kinds of soil, there are no rational grounds for having bare north walls and uncropped north borders. When I entered on one of my charges some sixteen years ago I found one of the north borders unoccupied with plants, save weeds, and that several attempts to get Morello Cherries to grow upon it ended in failure. On examining the soil I found it to be of a very heavy nature, and the subsoil an impervious clay. As no useful crop could be got from land of this kind, I determined to alter its conditions and make them more in keeping with the requirements of plant growth. Whenever an opportunity presented itself in early autumn I had the soil and clay of a space the width of the border, 8 feet long and 3½ feet deep taken out. About 2 feet deep of the surface portion was wheeled to the opposite end of the border to be used for filling in later on. The bottom 18 inches was used to fill some holes in some ground adjoining the garden. I allowed about 3 inches of a fall from the wall to the outside edge of the border, and then sunk a drain 6 inches lower. The drain was formed with a kind of stone slabs like an inverted V, and on this and the remainder of the bottom of the border a foot of stones was placed on their edges. To protect this drainage from getting choked the stones were covered with turves, grass side downwards, and thus a section was completed. Finding the soil exceptionally heavy, a quantity of screened old lime mortar and plaster was obtained, then another section of 8 feet measured off and 2 feet of the surface of this mixed with the lime and

plaster dressings were thrown back on the prepared section. The whole border was dealt with in sections as other duties permitted me to take it in hand, and although it took two or three years to finish it, the portion prepared during the autumn and early winter was planted the following spring. I ought to have remarked that as the soil was such a heavy one and many crude compounds being brought within the range of plant roots, the whole was ridged and kept as open as possible while the work was proceeding. This enabled the frost and air to play a beneficial part in breaking up the masses and changing the composition of some of its constituents. Whenever the soil was dry in spring the ridges were levelled down, Morello Cherries planted to cover the wall, and Gooseberries to occupy the border, both of which soon filled their allotted spaces. These have continued to do well and yield useful crops. Among the Gooseberries were Aston and White Eagle, so far as I can remember, so that a late supply of both dessert and cooking varieties was secured by merely protecting them along with the Cherries from birds. Since then I have had to deal with north borders of a similar character of soil, and have treated them in much the same way, only I employed Gooseberries and Black Currants to cover both walls and borders. With Gooseberries to cover the walls I used double cordons planted at 2 feet apart, trained vertically, and adopted the spur system of pruning. As there was a space of 1 foot between each cordon ample light and air were at command, and the fruit of Aston was really fine indeed both as regards size and flavour: in fact, some gentlemen remarked that they were equal to Black Hamburgh Grapes. The Black Currants were also planted at 2 feet apart, and held to the wall with strained wire and holdfasts. In hot, dry seasons the crops from these were invariably fine, while in many instances those grown in the open ground suffered from drought, and were in consequence impaired.

Borders composed of sandy loam require rather different treatment. Provided the subsoil is a porous one, trenching 2½ feet deep will be all that is necessary beyond incorporating some well-decomposed farmyard manure and bonemeal with it. It is sometimes, however, nothing but sand a foot or 15 inches below, and as 2½ feet of a good root medium is desirable, the sand should be removed, and its place filled up with turfy loam or a fairly good loamy soil. Ridging should be avoided, as solidity is more needed in formations of a sandy nature, and when the sand predominates considerably over the clay and organic matter, treading will prove conducive to the well-being of the plants grown upon it. The fruits to suit soils of this light character are Red and White Currants, Raspberries, and some varieties of Plums which have twiggly growths, such as Rivers' Early Prolific and The Czar. The Currants, like the Gooseberries, are best as cordons for the walls, and the Raspberries as single canes. Plant the former at 2 feet and the latter at 6 inches apart. The Plums are best planted from 12 feet to 15 feet apart, trained in fan fashion, and the young wood laid in annually to supply the crop. The time of ripening of these early varieties of Plums will be retarded, and they will form a good succession to those grown in a more favourable position. As the sandy soils of which these borders are formed quickly become impoverished, it will be necessary from time to time to give them the benefit of a fertiliser. Among natural manures farmyard liquid holds the first place, and, seeing that no deep digging should ever be done once the borders are planted, this

is decidedly the right thing to employ, and the winter months the time to apply it.

J. RIDDELL.

White Grapes. There is little prospect that Muscat of Alexandria will be ever deposed from its high position as the best and finest flavoured white Grape. Two new white varieties were submitted to the fruit committee on the 6th inst. Gradiska has berries of medium size, almost transparent, and nice bunches, but the fruits when tasted proved quite devoid of flavour. It was even inferior to Buckland Sweetwater, sent for comparison. Worse still were the gigantic greenish white berries of Centennial. These fruits, of almost the dimensions and with just the long form of smallish Victoria Plums, when cut open were found to be comparatively hollow. It is to be hoped that it will not get into commerce. White Gros Colman, Duke of Buccleuch, and Golden Champion, all better than this one, have not been successes.—A. D.

Melon British Queen.—This exceedingly handsome golden-coloured and finely netted variety, having pure white flesh, received, at the hands of the fruit committee the other day at the Drill Hall, the unusual award of a first-class certificate. White flesh in Melons has, as a rule, given the poorest of flavour. This one gave flavour of so rich a description that the committee regarded it as not only the very best flavoured white-fleshed Melon yet brought to the table, but one of the richest flavoured of any colour; hence the high award. No variety has shown more perfect form than has British Queen. It is one of the Frogmore seedlings, and Mr. Thomas is to be congratulated on getting so delicious a variety. It is hoped that all of the other fine fruits of it shown would have exhibited the same very high quality.—D.

Peach Violette Hative.—As an all-round variety for culture inside and out this useful Peach will be hard to beat. It is a good grower and certain to crop, and if not too heavily laden the fruit is large and of good quality. Often a good-flavoured Peach gets a bad name when the tree is so heavily cropped that over-feeding has to be resorted to, for although the excess of feeding will enable the tree to lay the flesh on the fruit, there is sure to be a loss of quality. Violette Hative is a Peach that if reasonably treated will finish up an immense crop of really good fruit, provided the tree is healthy, and this is always of fine flavour if caught at the right time. It is a mistake to leave it on the tree until it drops, for it is then beyond its best, but it must not be gathered too early. A fairly large tree here in an unheated house has been fruiting well, and I go over it once every day, removing all fruits that will part from the tree without damaging the wood. It is one of the best Peaches for packing, as the flesh does not grow over the wood so much as that of many others, consequently the fruit is gathered without bruising. It is also firm in texture even when fully ripe, owing to the rather thick skin. The flesh is greenish yellow, very bright red at the stone, from which it parts readily.—R.

Yellow Ingestre Apple.—I observe that this pretty little dessert Apple is commonly classed as Summer Golden Pippin. That classing seems to have arisen from some confusion, possibly because some not too careful nurseryman has sent out one for the other. It was odd that this matter should have cropped up the other day at the Drill Hall, where Messrs. Veitch and Sons had a fine collection of early Apples, and amongst them were dishes of both Yellow Ingestre and Summer Golden Pippin. Having examined and tested both, I found it was not at all difficult to dissociate one from the other. The Ingestre, originally called Ingestre Pippin, and raised many years ago by Mr. T. A. Knight, of Downton Castle, with the Red Ingestre at the same time from the same fruit, is a very popular one in market orchards, and always commands a

ready sale. But in the market the Summer Golden Pippin is unknown. The latter ripens early in September, whilst the Ingestre is ripe at the end of September and early in October. There is no other Pippin which will be mistaken for a proper sample of the Ingestre. The variety Messrs. Veitch and Sons have as Summer Golden Pippin more exactly resembles what Rogers in 1834 described as Autumn Golden Pippin, also ripe at the end of September, but which is broader and has a more open eye than has the Ingestre Pippin; the flesh also is firmer. The Ingestre is notably a variety that fruits on the points of the shoots. It should only be thinned. Standards never grow large, and become somewhat drooping in form. It would be very useful could trees of all these Yellow Pippins, Summer, Autumn, Ingestre, Wyken, Golden, Kirke's Golden, Pitmaston, Downton, and others, be planted somewhere so that individuality and uses might be determined.—A. D.

PEAR BEURRE BOSCH.

ALTHOUGH this variety has a high reputation for flavour and the fruits are of good size, it is by no means a select or high-class one generally; indeed, it seldom comes into lists of the best recommended for ordinary cultivation. Whilst it fruits freely on standards in East Kent, where it is largely grown for market, yet is its quality good only where the soil is warm and deep. It seems to like to be near to the sea-coast and on chalk. Inland and in gardens the tree needs to be grown against a wall to enable the fruits to develop their best properties. When grown as a bush or standard the fruits come somewhat hard and deficient in flavour. It is doubtless because of this defect in its character that it is little grown and less seldom recommended for culture. When really fine, clean, well-developed fruits are produced, then flavour and quality of the best are found. In such case the fruits are large, pyriform, and have skins of russet, much speckled with cinnamon; the eye is open and the stalk $1\frac{1}{2}$ inches long. Its season of ripening is in October and November, a time of the year when so many others, and on the whole superior Pears, are ripe, and when, indeed, because they cannot be all consumed before being decayed, so many fine fruits are wasted. We have of early and midseason Pears enough, and of the best it will be hard, as more recent novelties have shown, to excel them. But we could well do with December and January Pears, and were Beurré Bosch but a late ripener it would then be so much more worthy of good wall culture. D.

Mulching fruit trees.—Not for many years has the value of mulching or top-dressing fruit trees with a good coat of manure been so apparent as at the present time, for the difference in the look of trees so treated and others left to withstand the trying ordeal of long protracted drought is most marked, and should convince the most sceptical that this should form one of the principal necessities of fruit culture, at all events, in light soils that are liable to be quickly dried through. Having had a good many dry seasons during the past few years, I had nearly all my wall fruit trees, and a good many in the open, well mulched with fresh stable manure early in the season, for we started the year with a dry subsoil, as the winter, although so mild, was remarkably dry, consequently there was no reserve of moisture in the soil. Although the early part of summer was cool, with light showers, sufficient to keep the surface-rooting crops from taking any harm, it did not take long when the excessive heat and drought set in to show that the trees that were left exposed were feeling severely the effects of the trying ordeal. I never remember to have seen crops of all kinds droop and flag in so short a time

as they did this year, for when the roots were not protected, Raspberries that were promising a good crop one week were gone beyond recovery the next, as the heat was excessive and the nights as dry as the days. In applying mulching it is of little use to place it just round the stem, for the best feeding roots are certainly as far from the base of the tree as the topmost shoots of the tree are in height, and the only effectual plan is to keep the border solely to the use of the trees and mulch it all over 6 inches thick.—J. G., Gosport.

ROOT-PRUNING FRUIT TREES.

I HAVE read with interest the article on p. 169, and doubtless under certain conditions the operation is decidedly beneficial. The necessity for the same, however, depends wholly on soil and situation, and although it may be practised with success in one part of the country, it is worse than useless in another. I write "worse than useless" because the checking of root action, instead of being followed by a proportionate increase of fruit, has a directly opposite influence. I remember, for instance, some years ago, in the course of correspondence with a friend who then filled a post in Devonshire, where the rainfall was considerably above the average and the soil heavy, asking the question as to how Peaches and

Pear Beurré Bosch.

Nectarines did with him, and the reply was, "Very well, if I lift the trees every second or third year." The necessity for discrimination in the matter is obvious when I say that if the practice were followed here fruit would be conspicuous by its absence, and even if a thin crop set it would be small and practically worthless. If circumstances necessitate the removal of anything in the way of stone fruit from one wall, or one part of a wall, to another, no fruit is obtained the first year, and the greatest length of growth made even on leaders would not exceed 4 inches, despite every care and attention alike in removal and replanting, in watering and mulching. Fair growth and a small crop are obtained the second year, but it is not until the third season that the trees are thoroughly at home, and it seems to me that on light, dry soil there is something lacking in the way of strength and vigour which prevents recuperation after the check of removal. I am not questioning the wisdom of root-pruning on some soils. The above is the result of sixteen years' experience in West Surrey with a naturally light soil, sand 2 feet from the surface, and very little facility to acquire heavier compost. The above remarks apply to Pears and Apples as well as stone fruit, especially bushes, pyramids, and

espaliers on the Quince and Paradise stocks. It is in the highest degree desirable so to plant that the trees may not require removal, and the ground about them cannot well be kept too firm. Given a wet autumn and winter I get strong growth, but root-pruning is never practised. The non-restriction of leaders for a season, an occasional thinning out of main branches, and not too close pruning of side growths answer the purpose better than any curtailment of root.

E. BURRELL.

MILDEW ON VINES.

BY way of supplementing Mr. Iggulden's excellent instruction for the eradication of mildew on Vines (p. 180), I would detail my mode of operation in dealing with a very bad attack, as it varies a little from that referred to. When I took charge of the gardens at Duncombe Park I found all the healthy young Vines, in a range of new vineries about 200 feet in length, completely covered with mildew. The Vines had been planted the year previous and had made strong growths, which vigorous state of health they were making an effort to maintain when they came under my care. Most of the canes were carrying a couple of bunches of Grapes each. These, the young wood, and foliage were covered with the fungus.

As the fruit would never have been of any use it was cut off and every portion of the plants dressed with sulphur, rubbing it on the canes and young growths with the finger and thumb. A vigilant eye was kept on the leaves and new wood during the growing season for any fresh attacks, and when seen they were treated to a dose of sulphur.

The Vines were pruned in early winter, the glass and woodwork of the houses scrubbed with hot water and soft soap, and the walls washed with quicklime and sulphur. The canes themselves were painted with a mixture of clay and sulphur, the latter forming the major portion, and the surface soil of the borders was removed and replaced with new. In spite of this measure of prevention, mildew reappeared the following spring just as the Vines were coming into flower, and even although a certain warmth was maintained in the hot-

water pipes at all times and a stuffy atmosphere avoided, yet I could never clear it out by the use of sulphur and cleansing. Every year it returned at the usual time, and was easily detected on the leaves by its giving them the same appearance as an oily substance would produce on paper—making transparent blotches. Although I could secure good crops—the Vines being unusually vigorous—still, a few berries in every bunch were more or less disfigured. My attempts to get beyond the stage of immunity from mildew induced me to conclude that some of the germs must find winter quarters in the soil of the borders, and led to them being dressed with sulphate of iron. The year following the dressing not a vestige of the evil could be seen, and, as far as I know, it has never made its appearance since.

I again had to deal with mildew on the Vines in my next charge, and here the sulphate of iron did its work in an equally satisfactory manner; therefore, feeling convinced of its efficacy as a specific for mildew germs, I would advise "J. H. F." to try its effect on the floor of his house after carrying out Mr. Iggulden's instructions. Sulphate of iron should be obtained in a finely ground form and applied at the rate of

2½ ozs. to the square yard, and washed in immediately it is applied. It can be obtained from any large agricultural manure manufacturer.

J. RIDDELL.

Name of fruit (S. E. F.).—Your Plum is evidently the old Winesour, but unless shoots to show whether the wood is smooth or downy be furnished, it is not easy to give a correct reply. We are rather surprised to learn that the Plum is esteemed for dessert. In that respect it is far below the merits of our ordinary cooking Plums. The flesh is acid, and leaves in the mouth a very unpleasant bitter taste. Used for preserving with plenty of sugar it is useful, as the flesh is firm. There are many better varieties in commerce. Thus if you had young trees of Rivers' Early Prolific, Czar, Victoria, Emperor, Monarch, Archduke, Jefferson's and Oullin's Gages, you would have of the finest for cooking and good for dessert.

Apple Beauty of Bath.—For a very early Apple this sort is, I think, far superior to any of the older early dessert kinds. This season it has been better than usual, the fruits having grown to a good size. They have coloured well, and the flavour is excellent. It is a great acquisition in a private garden, as the fruit serves to augment the dessert after Gooseberries are over. I find it a good grower, a free cropper, and it succeeds remarkably well as a bush. I should also imagine, judging by its habit of growth, that it would make a good standard. In the course of conversation with a grower for market a day or two ago he mentioned this variety as one he thought of planting somewhat extensively, as the fruit commands a ready sale.—A. W.

CHRYSANTHEMUMS.

CHRYSANTHEMUM W. H. LINCOLN.

This is undoubtedly one of the best all-round Chrysanthemums in cultivation. It is possible to produce fine blooms of this variety quite early in the autumn and to ensure a good supply of fresh flowers up to February. Some five years ago a London market grower created a sensation by bringing splendid blooms into Covent Garden quite a month before the large-flowered kinds made their appearance, and he had no difficulty in selling them at 18s. per dozen. It is not only that this Chrysanthemum can be had in good condition some four months in the year, but it is of such a robust habit that it will produce an abundance of nice blooms under treatment that would fail to give satisfactory results with the major portion of the larger flowering kinds. For this reason it should be grown largely by those who wish to obtain a quantity of cut blooms of good quality with a minimum of labour. Last year I had some plants in 8-inch pots that yielded individually about four dozen blooms of fair size at the latter end of January. These were grown in about as rough-and-ready a way as it is possible to treat Chrysanthemums when cultivated in pots. They bloomed in the same pots the previous year, and were not in any way disturbed. They were cut back rather hard, were set out of doors in April, and watered in the usual manner with the addition of an occasional dose of liquid manure from the time they came into free growth. They made specimens each 3 feet across, and gave me really good blooms the last week in January. It is not many Chrysanthemums that would yield such good returns under similar circumstances. The best results are, I think, to be obtained from plants that have been bloomed in 6-inch pots and are shifted into 8-inch pots in July. Cuttings struck in April

will make nice little specimens carrying half a dozen or more blooms, and the natural habit of this Chrysanthemum being dwarf and compact, such plants are of great service for window decoration, finishing off groups, or for any purpose where dwarf things are required. For late blooming stopping is not necessary. W. H. Lincoln, like *Boule de Neige* and *Golden Gem*, makes naturally such a late break, that if the shoots are pinched in June or July, as one must do with many kinds, there is a danger of the buds not opening. If the plants can be kept out in the open until about October 15, and no more fire applied than is necessary to exclude frost, there will be plenty of good blooms to cut through January.

J. C. B.

CHRYSANTHEMUM NOTES.

UNLESS we soon get rain the early flowering varieties in open borders will be a comparative failure, the growth being stunted and sparse. *Myehett White*, by its earliness and the good qualities of its blooms, seems by far the best of recent sorts in the section. In any ordinary season it would be fine for open-air culture. One could wish that it were more easy of propagation, for it deserves wide distribution. *Mme. Marie Masse* is a first-rate pink variety, being so free and early. The absence of rain does not, however, affect Chrysanthemums generally, as by far the greater portion is grown in pots. *Sunshine* is what they delight in—at least, it is conducive to ripened wood, without which it is hardly possible to obtain satisfactory results. This favourite autumn flower has such a hold upon the many persons who cultivate it, that one rarely meets with a neglected collection. That is to say, it is not common to find Chrysanthemums suffering through want of water; they somehow get what they need in this direction. It is not so rare to find the plants overdone, however, especially in the way of feeding with manures. Year by year one finds over-fed plants in abundance. The big stems and leaves are certainly fascinating, but the "big blooms" so many appear to desire are not often observed resulting from large, sappy stems. My ideas in this matter are that all one requires to produce specimen blooms of Chrysanthemums with good shape, size and colour is a long season of steady growth, a sweet, porous soil and plenty of light and air. Under such conditions, given the necessary attention as to water, the plants will make ample roots. If these be stimulated during early autumn after the soil is practically exhausted, the wealth of bloom is sure to be excellent.

Chrysanthemums up to September have had an ideal season, although, by their never-ending wants, they have taxed the grower's time to a considerable extent. Twice or more each day one requires to satisfy their thirst, but the stems are hard and the leaves of a sturdy hue. Rough, almost prickly spines form along the stems of many plants where grown for large flowers; this is a sure indication of ripened wood, such as is bound to unfold fine blossoms. Most of the buds are secured—that is, all side growths have been removed and flower-buds only left at the points of the limited number of stems each plant is allowed to develop. These are swelling rapidly and point to an early season. It is always well to have the bloom-buds in this condition whilst the plants are outside, so that they benefit by the heavy dews at this time of the year. If not formed or otherwise barely seen when placed under glass, the latter has a tendency to draw them up spindly. Being in an open spot, earwigs give but little trouble, but with many cultivators they are a source of annoyance. This pest must be caught. Ill-formed blooms usually result from their ravages in the bud state. Where the flower buds are not so advanced as to show colour in the florets, the plants are best in the open until the end of the month, but if any should be in the above-named condition, lose no time in putting the same under cover. Damp is dangerous

to the blooms when opening. Many mistakes are made with Chrysanthemums when under glass. Too little air is one, and the want of moisture is another. At first, especially in sunny weather, it is well to make up in a slight way the absence of the natural dews by throwing water among the pots, or even lightly syringing the leaves.

I have not yet heard much of the new Chrysanthemum rust, but fear that it will spread when dull, showery weather comes. Whether it affects the blooms or not it will be well to observe. Most likely in many cases the black spots are not looked for because they form on the under-sides of the leaves. Complaints peculiar to certain sorts do not appear common this year. Thus the variety *Mme. Carnot* carries its foliage better than usual. *Australian Gold* in several instances had the appearance last year of being scorched just when the young buds were forming. But, thinking that after all it was the work of tiny thrips, I kept the points dusted with tobacco powder, and this year every shoot has produced its bud properly. The new kind *Marie Calvat*, from which much was expected, has a similar tendency, so that probably the two sorts named are especially sweet to the small Chrysanthemum foe. Only one variety in my collection refuses to grow under ordinary treatment, and that is a new sort, *President Nonin*. The blooms of this were much liked last year on account of the apricot tint in the colouring and fine shape, but in these days, when Chrysanthemums are so plentiful, I do not think it wise to bother one's self about "miffy" growers unless the flowers be of unusual excellence.

H. S.

Chrysanthemum propagation from rested plants.—One of the most noticeable facts in the culture of the Chrysanthemum this season has been the superiority of plants from cuttings taken from rested stock. More particularly is this seen in plants of *Vivian Morel* and the sports of this family, viz., *Chas. Davis* and *Lady Hanham*. Growing side by side are plants of these three varieties, each showing the different systems of securing cuttings. Those from cuttings taken from plants grown in pots the previous season and subjected to ordinary treatment are somewhat puny in their growth, with stunted and curling leaves, and looking anything but happy. On the other hand, cuttings taken from plants which were lifted from the open ground, after being there all through the summer and autumn of last year, have grown away freely, being taller, more robust, and partaking of all the necessary vigour to make good plants and now developing buds, which are most promising and distinctly ahead of those previously described. This proves how advantageous this method of preserving the vigour of the stock has become. There is evidence that the Chrysanthemum deteriorates after the first two seasons or so, and on this account, perhaps, it would be worth while to treat the stock as described above.—D. B. C.

Chrysanthemum Lady Fitzwygram.—Among the early-flowering Chrysanthemums this is not only one of the best, but also of the dwarfest type, and a most abundant bloomer. Veritable bushes of it not more than 20 inches high are a compact mass of buds, of which fully one half should be removed, even where ordinary-sized flowers are required. This is almost essential, not merely for securing even moderate-sized flowers, but equally so for ensuring a fair amount of stem to cut. One feature of the variety is the way in which even the earliest-formed buds will develop when allowed to remain on the plants, though these are of little use owing to the absence of stem. It is singular how many growers have failed with this early white, a circumstance I believe to be due to the material supplied them rather than any failing or shortcoming on the part of the grower. When first distributed the variety was made much of, and it is indeed a pretty white kind, and the stock, doubtless worked very hard to secure sufficient, resulted in much-weakened cuttings being distributed. In my own case, while according special treatment to

the few I had, the young plants absolutely refused to grow, and after a season's trial were thrown away. With a fair amount of disbudding it is a useful variety, and provides quite a profusion of its pretty white flowers.—GROWER.

NOTES AND QUESTIONS.

Chrysanthemum Louis Lemaire.—This is a distinct gain to the sorts suitable for outdoor culture, as it retains its colour so well. It is a bronzy red on a yellow ground sport from M. G. Grunerwald, and, like the parent plant, is a free-flowering variety. The foot-stalk and growths are not so strong as desirable, yet the plant is valuable on account of its other good points. It is of dwarf habit, like the parent plant.—C. A. H.

Chrysanthemum May Mauser.—There is plenty of room for novelties of the kind represented by this charming flower. The blossoms are distinctly neat and pretty, with fairly long twisting and curling florets of good substance and of an ivory-white colour, with a pale primrose centre. As represented in Mr. H. J. Jones's group at the Royal Aquarium last week, the plants were from 3½ feet to 4 feet high and flowering on the first crown bud from a natural break.—D. B. C.

Chrysanthemums in 6-inch pots.—These have done well so far this season, and are now among the most promising plants in several collections. Cuttings should be propagated during the latter days of February and early March. These plants are each carrying one large, plump bud, which in some of the easily-grown sorts is developing kindly, and there is little doubt a handsome display will be seen during October. The same varieties propagated a month later are equally promising for a November display and should be serviceable for grouping, as well as for providing fine individual blooms for exhibition. This method of culture has much to commend it, as the season of growth is comparatively short, and far less trouble is experienced in raising a batch of plants.—D. B. C.

DESTROYERS.

WASPS AND THEIR DESTRUCTION.

THE prolonged drought, associated as it has been with great tropical heat, has been altogether in favour of wasps, their nesting, and destructive work among choice fruits, both in the open and under glass. Hereabouts there appeared so few queens in the spring and early summer that a prospect of immunity seemed almost assured, or, at any rate, it was hoped their numbers would be such that much less mischief would be done with a corresponding decrease of anxiety on the part of those having charge of fruit either in small or large quantities. Such hopes, however, became in my case ruthlessly shattered, for never were wasps more numerous, notwithstanding that their nests to the number of sixty or seventy have been taken within a mile radius.

It is remarkable how deeply these pests have burrowed this year, many nests having been dug out at a foot to 18 inches below the surface. Some, too, were of extraordinary size, much larger, in fact, than a football, from which it might be inferred they were very strong, and the havoc committed really serious. Morello Cherries were first attacked, particularly some on a west wall and early ripened, because of the position being a warm and sunny one. Dessert Cherries on an east aspect curiously enough escaped their attention, and I was enabled to get an occasional dish off one tree from the beginning till the end of August—an experience quite unknown in any previous year. Plums, which are always in request with the wasp, were visited some time before they were ripe or even commencing to soften, and the same applies to Peaches and Nectarines on the open wall and indoors. The latter is quite a new experience here; in other

years, when numerous and active outdoors, they were, strangely enough, absent among indoor Peaches and Nectarines. They have not discriminated between ripe and unripened Grapes this season, contrary to their usual custom. In one range of small vineries Grapes were fully ripe in early June in one division, in another they were not ready until the middle of August, and yet the latter were chosen in preference, and but for frequent applications of Scott's and Davis's destroyers the crop would have been absolutely cleared. Speaking of the latter remedies, I am inclined to the opinion that the quality or constituent parts are not strictly uniform. I have come to this conclusion since its deterrent action is so infinitely inferior to what it used to be a few years since. A closely observant friend of mine once remarked to me that one bottle, ordered with his seeds in the early months of the year, was an absolute safeguard against loss, for, by applying the poison by the aid of a pointed stick to the fruit when first attacked, the wasps would immediately hasten away and for some days would avoid trees thus treated, and but little effort was needed to prevent their interfering again. For vineries I have in former years found these destroyers absolutely safe against attack, and muslin guards over the open ventilators were quite unnecessary. Not so now, for the combination of muslin and destroyer of either manufacture is not proof against their entry. If there is no difference made in the preparation, what accounts for the uncertain action? That there is possessed by it a strong poison, probably arsenic, is proved by the death of a few which venture to imbibe the tasty but treacherous drops measured by such infinitesimal quantity. It is decidedly regrettable that its action should be so uncertain, or at least fail to act up to what is expected and guaranteed by the vendors. It is only by repeated and frequent applications that any good can be done at all, and then the cry is raised, Still they come. In the garden Apples and Pears are similarly attacked, Pears in particular. After the endeavour to save a light crop of *Beurré d'Amanlis* by repeated applications of both kinds, the only alternative remained to gather and remove the Pears to the fruit room, and this in spite of the fact that they were not ripe enough even to gather. There was, too, a quantity of other Pears, and of Williams' *Bon Chrétien* in particular, which one would reasonably expect wasps to choose first.

DESTROYING THE NESTS.

The first and most important attack one can bring to bear on wasps is unmistakably at the nest, but in a district where fruits are widely and universally cultivated in the garden and orchard of the cottage, mansion and farm their increase is certainly encouraged. At some local flower shows prizes are given, and very wisely too, for the largest number of queen wasps, and it would be well if private individuals could take up the matter in the same way. Where it is carried out, much less trouble is caused from their visits in late summer, or, as I have so often noted, from the early Plum season until all Pears and Apples are stored. Early summer fruits, fortunately, are exempt from their interference, and there are districts and gardens, even in a year such as the present, where no trouble is known from wasp attacks. For destroying the nests, nothing I have tried is so quickly effective or so simple as cyanide of potassium. Needless to say, this is a deadly poison, and should be used with caution, but with ordinary care no one need have any fear. The great advantage

of this is that it can be applied much more effectively during the day, and thus the old-fashioned or tedious ceremony of burning them out at night is altogether dispensed with. Very strong nests, however, require sometimes a second application of the liquid; the dead and dying insects apparently, when so numerous, stifle down the fumes or vapour, which to them is so destructive. It is useless to visit a nest, apply a dose of cyanide, and then leave it, hoping that its destruction is assured, even if all the wasps on the wing pass in and remain in the nest. To those who have watched their progress, it is well known that those in the maggot stage hatch and re-establish the nest in a surprisingly short time. To obviate this, one must visit the nest with a spade only a few hours after the solution is applied, dig it out and beat it into a paste. Sometimes, when to outward appearance all is quiet, a quantity of winged and living wasps are disturbed in the course of digging out the nest. I have found a pot of water quickly thrown on them greatly facilitate their end. The cyanide supplied to me in ½-lb. or 1-lb. bottles is in lumps, which is easily dissolved in warm water, and I find it better to mix only as much as can be used at once, because the loss by evaporation is such that the solution is rendered almost valueless in a day or two. It should both in a dry and liquid state be carefully sealed against air. Two or three lumps, according to size, suffice for a pint of water, and a tablespoonful poured well into the entrance soon commits havoc among the inmates and those passing in. Nests are most easily found when the sun shines, because wasps are then traced for some distance on the wing, and the direction of their nests can be often ascertained by noting the course taken on leaving the fruit trees. Bottles filled with sugar and beer, or honey and water, attract and destroy a quantity of wasps and the large blue-bottle flies, which, when in quantity, are almost equally as destructive. This perhaps is the only means of trapping the flies in question, and it is surprising the quantity collected in large sweet bottles when partly filled with a tempting mixture.

Road Ashton, Wills. W. STRUGNELL.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

FROM the trial grounds of the Royal Horticultural Society Gardens, Chiswick, several varieties of Onions and Potatoes, also one of Beet, were sent to the last fortnightly meeting. These had been previously approved by the fruit and vegetable committee, which met there on the 30th of last month, and were brought up to be duly confirmed. Onions were exhibited both as spring and autumn sown in each variety, this being a very good test. Below are given the names and description, all receiving awards of merit:—

ONION BOKOLD'S BANBURY CROSS.—A large, flattish-round Onion. From Messrs. J. Nutting and Sons, Southwark Street.

ONION WROXTON.—A fine round Onion, good both in spring and autumn. From Messrs. Watkins and Simpson, Exeter Street, Strand.

ONION ROUSHAM PARK.—Also good, both as spring and autumn. From Messrs. Watkins and Simpson.

ONION NUNEHAM PARK.—A good white Spanish variety, well known. From Messrs. J. Nutting and Sons.

ONION HURST'S BANBURY CROSS.—Large and firm, a good main-crop kind. From Hurst and Sons, Houndsditch.

POTATO THE MAJOR.—A white, half-long kidney. From Mr. E. Webber, Worcester.

POTATO MISS ELLEN TERRY.—A round white form; a great cropper. From Mr. E. F. Blinco, Haddon Villas, Hucknall Torkard.

POTATO FISHTOFT SEEDLING.—A fine white kidney potato, large, and an excellent cropper. Messrs. Johnson and Son, Boston.

POTATO CHALLENGE.—A heavy cropper, tubers white, flattish round in shape. Mr. R. Sydenham, Tenby Street, Birmingham.

POTATO DEVONIAN.—White kidney of medium size, of superior flavour, and with a thin skin. Mr. O. Thomas, Windsor.

POTATO FOO.—An excellent kidney variety from the Canary Isles. Mr. J. Wright, Wandsworth.

POTATO FIDLER'S QUEEN.—Another good variety both in shape and flavour. Messrs. Fidler and Sons, Reading.

BET RED GLOBE.—This is a fine deep-coloured form of the Egyptian Round. From Messrs. Watkins and Simpson, Strand.

NEW DAHLIAS AT THE CRYSTAL PALACE.

Of the show and fancy types but very few new varieties were staged, and but two certificates of merit were awarded, viz., to

DAHLIA DAVID JOHNSON.—A well formed self show variety, good in petal and shape, and highly promising; the colour salmon, the reverse of the petals flushed and pencilled with delicate purple. This came from Mr. Geo. Humphries, Chippenham. The other certificate was given to

DAHLIA WATCHMAN.—Yellow, flaked and pencilled with deep crimson, and though in its colour and markings like one or two already in cultivation, yet quite distinct, and a valuable addition to this section. It came from Messrs. Keynes, Williams, and Co., Salisbury.

The additions to and improvements in the true Cactus varieties go forward by leaps and bounds. All the fears originally expressed that with cultivation the distinctive character of *D. Juarezii* would become lost have, happily, been falsified; it has become both intensified and refined, and concurrently appears a decided and much-needed improvement in the habit of the plants, as they are more free-flowering and throw their blooms well above the foliage. Some of our choicest varieties fail in these respects, but there is reason to hope their progeny will show manifest improvement. A large number of seedlings was staged at the Crystal Palace, and of these the following obtained certificates of merit:—

DAHLIA MAGNIFICENT.—The ground cream, suffused with delicate salmon-pink, a singularly beautiful and distinct variety, with, it is said, a most desirable habit of growth. From Mr. J. Strudwick, Silverhill, St. Leonards-on-Sea.

DAHLIA MRS. HOLFORD.—Bright scarlet in colour, a small-flowered or pompon variety of true Cactus shape, and which, judging from the sample sent, is very free and throws its blooms well above the leaves. It was recognised as a garden variety for decorative purposes. Messrs. Keynes, Williams and Co.

DAHLIA COUNTESS OF LONSDALE.—Orange-salmon, the tips of the petals suffused with delicate purple: one of those exquisite salmon shades so much valued for decoration. Messrs. Keynes, Williams and Co.

DAHLIA CLOWN.—A singularly novel variety, the deeply fluted petals very pale orange-red, distinctly tipped with white. This is in the way of *Arachne*, but larger and bolder in all its parts, and makes a fine and striking bunch for exhibition. Messrs. Keynes, Williams, and Co.

DAHLIA LUCIUS.—Bright salmon-scarlet, suffused with orange; a variety of great refinement and distinction. It was selected as the best new Cactus Dahlia in the entire exhibition. Messrs. J. Burrell and Co., Cambridge.

DAHLIA ANTELOPE.—A bright cerise-scarlet flower, with a flush of orange in it; in the way of *Fantasy*, a type which exhibitors are seeking to improve and extend. From Messrs. J. Burrell and Co., Cambridge.

DAHLIA CLARABEL (Pompon).—Cream, tipped with crimson-purple; a distinct and attractive variety of fine shape and quality, medium size, and quite compact. From Mr. Charles Turner, Royal Nursery, Slough.

DAHLIA SNOWFLAKE (Pompon).—A highly refined pure white variety of medium size and perfect symmetry. From Mr. M. V. Seale, Sevenoaks.

DAHLIA LESLIE SEALE (Single).—This has a dark crimson ring round the eye and a margin of pale lilac, distinct and attractive. From Mr. Seale.

DAHLIA ERIC (Single).—Orange, with deep edge of salmon flushed with delicate mauve; a finely-formed variety. From Mr. T. W. Girdlestone, Sunningdale.

Dahlias at the Aquarium.—At the Dahlia exhibition at the Royal Aquarium, on the 6th inst., a representative jury of exhibitors and growers awarded certificates of merit to the following:—Cactus Dahlia Magnificent (J. Strudwick); Cactus Ranji, shown in very fine character (G. Humphries); Cactus The Clown, Viscountess Sherbrooke, and Countess of Lonsdale (Keynes and Co.); pompon Dahlia Madeline (C. Turner); show Dahlia David Johnson (G. Humphries); pompon Dahlia The Duke (Keynes and Co.); single Dahlias Columbine, Louise, and Tommy (T. W. Girdlestone); pompon Dahlias Snowflake, Distinction, and The Demon, and single Leslie Seale (M. V. Seale); and Cactus Dahlias Lucius and Antelope (J. Burrell and Co.).

United Horticultural Benefit and Provident Society.—The annual dinner of this society will take place at the Holborn Restaurant on Wednesday, October 5, at 6.30 p.m. Mr. George Bunyard, of Maidstone, has kindly consented to preside.

Royal Horticultural Society.—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, September 20th, in the Drill Hall, James Street, Westminster, from 1 p.m. to 5 p.m. A lecture on "Fruit Growing in Suburban Gardens" will be given at 3 o'clock by Mr. W. Roupell, F.R.H.S.

NOTES OF THE WEEK.

Spiræa tomentosa alba.—I send you flowers of the new *Spiræa tomentosa alba*, a very distinct shrub.—T. SMITH.

*** This is a very good as well as a distinct shrub.—ED.

Dracæna Duchess of York.—While this new-comer cannot boast of the brilliant colouring of many members of this family, it certainly possesses a grace and beauty that will render it welcome in many ways, though more particularly, perhaps, as a table plant. Thus employed, the narrow, gracefully recurving leaves will produce a very desirable effect.

Cytisus nigricans.—Among late-flowering shrubs this yellow Broom should not be forgotten. It is especially valuable to brighten up at this season beds or borders in which evergreen shrubs are largely grown. I saw *C. nigricans* the other day in a bed in which was a quantity of *Rhododendrons*, and the bright sprays of yellow flowers were very pleasing and helped to lighten up the bed.—S. ARNOTT.

Solanum pensile is a very beautiful stove climber from South America, quite free, though not excessive or rampant in growth, and producing numerous drooping clusters of flowers of a violet-mauve shade. The blossoms individually are not large, but in the free manner of their production have a decided and pretty effect, the clusters of flowers drooping very considerably. Plants of this were flowering freely in the aquatic stove at Kew recently.

Primula obconica.—Some very compact and freely-flowered examples of this species may now be seen in the greenhouse at Kew, where in small pots the plants are arranged in masses on the side stages, where the grouping becomes quite effective. In large batches such as this considerable variation may be noticed in the seedlings, and these doubtless in time

and by farther development will form the basis of an improved strain of this very useful flowering *Primula*.

Begonia coccinea.—This is a very useful and free-flowering species, that when required will cover a considerable space with its abundant succulent growth and blossoms. These latter are small and of the old type. Yet such plants in certain positions in the greenhouse possess an undoubted value more from the standpoint of a floral screen perhaps than ought else. It requires space for its rather numerous branches, and with these well developed comes a most abundant flowering.

Rudbeckia purpurea is now one of the finest of border perennials, and very showy withal by reason of its distinctly coloured heads. Few summer-flowering plants are more suited to grouping freely in the garden, and few, indeed, are capable of producing so fine a display of colour. Not only is it good and distinct in colour, but the habit of the plant leaves nothing to be desired, its strong self-supporting nature rendering sticks quite unnecessary unless in much exposed places.

Meadow Saffrons.—These pretty harbingers of early autumn are now fast pushing into flower in grassy places and other spots where they have been planted. In no place do they appear to so much advantage as when pushing up their lilac-rose buds in the short fresh green grass, that more than compensates for the natural bareness of their appearance. Quite a large number may be seen so planted and now flowering at Kew, not all in one place happily, but dispersed hither and thither.

Belladonna Lilies.—The Belladonna Lilies are now among the gayest of bulbous flowering plants, the bulbs, where these are strong and well established, throwing up quite a profusion of flower-spikes and large, handsome blossoms in a charming variety of shades that cannot fail to produce a rich display. All that is needed to succeed with these things is a deeply-prepared bed of sandy soil or peat and loam in equal parts and some old mortar rubble intermixed. This and a comparatively dry and warm position usually suit them admirably.

Yellow ground Carnation Cowslip.—This is one of the best. Just now I am gathering the most perfect blooms from it. Certainly no other variety comes near it as an all-round useful variety. I shall layer every shoot of it. This autumn flowering would lead one to believe it would make a good pot Carnation. Those I am writing of were planted out last October, and have stood the last winter better than many. The growth is strong and sturdy, the flowers perfect, and do not bust.—J. TAYLOR, *Hardwicke Grange, Shrewsbury.*

Begonia echincephala.—Some well-grown examples of this handsome and free-flowering species have been for some time past in bloom in the greenhouse at Kew. The plants in question are some 6 feet high and are bearing numerous trusses of the pinkish white flowers, the latter heavily studded externally with bristle-like hairs. This fine species, although a great attraction in large plants such as this, may be flowered quite well in small pots, and in this way prove of considerable service. In the large conservatory a few plants of this attractive species are ever welcome.

Zauschneria californica.—Just now this is one of the brightest and most attractive plants in my garden. The scorching sunshine of the last few weeks seems to have suited it admirably, for while other border plants have been drooping under the influence of the phenomenal heat, this has retained its freshness and makes a welcome spot of vermilion colour which catches the eye at once. It is growing in a south border, under the shelter of a dwarf wall, exposed to the full power of the sun's rays, and appears perfectly happy in its surroundings. It is exceedingly useful for cutting.—A. E. GIBBS, *Arden House, St. Albans.*

Colchicum Bornmulleri.—Bornmuller's Meadow Saffron is the largest and most effective of the *Colchicums* with which I am acquainted, surpassing in size the fine *C. speciosum maximum*. It is a very reliable plant here, and since I first purchased it a few years ago it has increased rapidly. The flowers are very pale in colour when they open, but afterwards deepen rapidly until they become deep purple, with a broad white zone at the base of the interior. A clump of this *Colchicum* is very pleasing, showing the various stages of colouring, passing from ivory-white and ivory-white flushed rose to deep

purple. The leaves in summer are very handsome.—S. ARNOTT, *Carsithorn*, by *Dumfriess, N.B.*

Bamboos flowering out of doors.—It may interest your readers to know that the rare event of a Bamboo flowering in the British Isles is at present occurring. *Arundinaria auricomma* is flowering at Castlewella, in Ireland, and at Batsford, in Gloucestershire. It is probably showing flower wherever it is grown, and it will be important that those in whose gardens it grows should note—1, any exceptions to its flowering; 2, whether the plants die after seeding; and 3, whether the seed ripens and germinates.—A. B. F. MITFORD.

* * This same Bamboo is also flowering at Kew, as will be seen by a note in the present issue (p. 214).—Ed.

Macrotomia (Arnebia) echioides.—The few sprays of blossom that make this excellent plant gay at the present time are, perhaps, more welcome than its fuller complement of spring flowers when there is so much of interest and beauty daily coming into bloom. Just now, however, flowering alpine or rock plants are scarce, the most profuse among all being a few Campanulas, such as *C. garganica* and others. In the midst of this dearth, the sulphury and yellow blossoms, with the black spots very prominent here and fast fading there, always make this an interesting subject, and as such and of easy culture it is worth growing freely.

Desmodium canadense.—This hardy herbaceous plant is not much grown, I fancy, except in botanic gardens, but it deserves a word of commendation. It throws up stems 4 feet or 5 feet in height, clothed with rather large ternate leaves, and bears terminal spikes of small rosy purple flowers. It is worth growing in suitable situations if only for the fresh bright green of its foliage. I raised it several years ago from seed supplied by Mr. Thompson, of Ipswich, and it has made itself quite at home in a London garden. It is extremely hardy, flourishes in any soil, and even the exceptional heat and drought of the past few weeks have had but little effect upon it.—K. C., *Kensington*.

Enothera macrocarpa.—Has any reader of THE GARDEN adopted the experiment of pinching or otherwise stopping the shoots of this showy plant with a view to getting a later bloom? If not, it is worth doing in those gardens where a late display of such things is valued; or, again, when a prolonged succession of flower is looked for. All that is needed is to remove the point of the growth in the early stages; a few may be so treated a second time. A similar plan may be adopted with spring-struck cuttings, removing the tip of the shoot as soon as the young plants are potted and have taken to the fresh soil. Few plants are so showy as this Evening Primrose, and such things are worth retaining in our gardens to the fullest possible extent.

Salvia splendens grandiflora.—A superb display of this brilliant plant may now be seen at Gunnersbury House, the residence of Mr. Leopold de Rothschild. The plants, which are growing in 10-inch or 11-inch pots, are close upon 4 feet in height, and are a blaze of colour. Mr. Hudson has arranged the whole of the plants on the floor in one of the new spacious fruit forcing houses in these gardens, which, taken all in all, are models of lightness and simplicity combined. There are about 100 of these *Salvias* of exceptional vigour, freely branched and densely furnished with the vermilion-scarlet flowers. It is worthy of remark that so brilliant a colour should have borne the recent great heat with impunity, the blossoms individually lasting a long time in good condition.

Helianthus Miss Mellish.—This Sunflower is, I think, unusually fine with me this year. The long spell of dry weather we had in summer appears to have suited it well. The flowers are large and brilliant in colour and the longer the plants become established the more vigorous do they seem to become. It is perhaps hardly fair to so fine a plant to indicate a fault, but it has one, and that is its rapid spread at the roots by means of underground runners. This rapid

increase is also a merit, as it is when seen in quantity that it is most effective. One occasionally sees in gardens that other and inferior Sunflowers have been substituted for the true plant. H. Miss Mellish was originally found in a garden by Mr. Joseph Mallender, head gardener to Miss Mellish, of Hodsock Priory, and was named in honour of that lady.—S. ARNOTT.

Passiflora Constance Elliott in Kirkcudbright.—On the garden front of Orchardton, Castle Douglas, N.B., the seat of Mr. W. D. Robinson-Douglas, is a fine plant of *Passiflora Constance Elliott*. Last week it was blooming profusely, although many of the earlier blooms were over. Since the memorable winter of 1894-95 it has suffered little in winter, and seeing that it survived the almost arctic season referred to, it is likely that this charming white Passion Flower will live for many years. This is interesting, as, so far as I am aware, there is not a similar example in the S.E. of Kirkcudbrightshire. The climate at Orchardton is mild in winter from its proximity to the Solway Firth, and Mr. Robinson-Douglas's success with *Passiflora Constance Elliott* and other choice shrubs shows how well adapted a great part of the west of Scotland is for testing reputedly tender plants.—S. ARNOTT.

Tricuspidaria hexapetala in the south of Scotland.—Some of us have recently written in praise of this distinct plant in THE GARDEN, and some have been surprised to hear of its success with Mr. Osgood H. Maekenzie at Inverewe, in Ross-shire. Judging from several most interesting letters I have had from Mr. Mackenzie, he can successfully grow on his gravelly soil plants we fail with in the south of Scotland. Although I had resolved to try *Tricuspidaria hexapetala* (*Crinodendron Hookeri* of some) in my garden, it was with considerable hesitation. It was with pleasure, therefore, that I saw it this month in the rock garden at Orchardton, in S.E. Kirkcudbrightshire. Its normal blooming season is long past, but two flowers were nearly fully open and a large number of buds were also formed. The buds appear to form early for the succeeding season, and the difficulty experienced in some districts in flowering the *Tricuspidaria* seems to arise from these buds being injured during winter. At Orchardton *T. hexapetala* is not grown on a wall, but as a bush in the rock garden. Here, from its being on an elevated position, one can see the flowers well. From the way in which this plant thrives here, one may hope it will prove amenable to cultivation in more gardens than could be expected from its Chilean origin, although we have a considerable number of hardy plants from that region.—S. ARNOTT.

Two good Kniphofias.—*Kniphofia Pfitzeri* is one of the most useful of the Torch Lilies, its sturdy spikes of a bright orange scarlet colour standing well above the plants by which it is surrounded. With me it proves to be a vigorous grower, and apparently appreciates the liberal dressing of well-rotted manure which it gets each spring and autumn. I have noticed that Mr. Maurice Prichard, of Christchurch, usually shows some very fine spikes of this plant in his exhibits at the various flower shows, and it is to him I am indebted for the introduction of this plant into my garden. Another good *Kniphofia* is *K. Macowanii*, the coral-red spikes of which are of a most pleasing tint, making it a great favourite of mine. Unfortunately, my plant was accidentally disturbed in the spring, and will not bloom so freely as usual this year in consequence. These two varieties should be in every collection. While speaking of *Kniphofias* it is worthy of mention that a plant of the ordinary *K. Uvaria* growing in a north border has this year thrown up as many as seventeen flower-spikes.—A. E. GIBBS, *St. Albans*.

* * * When recently at Saltwood Castle, near Hythe, we noticed on the grass a very handsome plant of *K. Uvaria* which was throwing up a profusion of its handsome spikes. At the same place a plant of *Vitis inconstans* on the walls of the castle was a blaze of rich colour. Thus seen in its

mantle of scarlet it is one of the most beautiful plants that one can grow for covering bare walls. It was planted in the grass and the position seemed to suit it in every way.—Ed.

M. Nabonnand.—The French Society of Rose Growers, at their congress held at Lyons on the 2nd of this month, conferred by vote the medal of the society, given to the Rose grower who has rendered the greatest service to Rose culture, to Monsieur Nabonnand, sen. (Père), of Golfe Juan, Alpes Maritimes. M. Nabonnand is the raiser of some Roses—such as G. Nabonnand—that to English growers will seem better than many medal kinds.

Fungus on grass.—Enclosed I send you some blades of grass covered with some golden-coloured fungus or something, my attention being called to it by a lady walking on the grass having her shoes covered with what looked like gold dust, and on my examining the grass I found it covered with it. I previously thought it had gone yellow from want of rain. This grass was sown about last May, and was put in very thickly. I shall be obliged if you can let me know the name of the disease, also a remedy.—THOMAS MAY.

* * * Your grass is infested with one of the corn or grass rusts, probably *Trichobasis rubigo vera*. As regards a remedy, I do not think there is much to be done. Watering lightly with Bordeaux mixture might be useful, but I doubt if it would be worth while to use. I do not imagine the grass will really suffer.—G. S. S.

The weather in West Herts.—Another remarkably hot week. On the 8th the shade temperature rose to 90°, which is 8° higher than any similar reading in September during the preceding twelve years, and 6° higher than any temperature recorded during either of the summer months this year. In fact, only once before in the past thirteen years has 90° been reached or exceeded at any period of the year. The previous night was also extremely warm, the temperature in the thermometer screen never falling lower than 61°, which is the highest minimum reading in September for twelve years. The ground during the week has been even more exceptionally warm than the air, the highest readings at 2 feet and 1 foot deep being respectively 67° and 72°; whereas the previous highest temperatures recorded in September have been for these depths 64° and 69°. On the hottest day (the 8th) the difference between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounted to as much as 22° at 3 o'clock in the afternoon. In no previous September has the air been so dry as indicated by this difference in the readings of these two thermometers. No rain has now fallen for over a fortnight, and no rain-water whatever has come through either percolation gauge for twelve days. The sun shone on an average for over 7 hours a day, the average for a September day being about 4½ hours.—E. M., *Berkhamsted*.

Hale Farm Nurseries, Tottenham.—We are asked to state that the above business has now been acquired by Mr. J. H. Osborne. It is intended as soon as possible to form the business into a limited company under the style of "Thomas S. Ware, Ltd."

Recreation ground for Swanley.—Sir William Hart Dyke, M.P., has notified his intention to hand over as a gift nine acres of land adjoining Swanley Junction Station, to be used as a recreation ground by the people of Swanley Junction and the neighbourhood.

A new white Everlasting Pea.—Will anyone tell me what is the correct name of the fine new white Pea shown at a recent meeting of the Royal Horticultural Society? It is so described that it may either be *Lathyrus grandiflorus albus*, which would be a splendid new thing, or *Lathyrus latifolius albus* var. *grandiflorus*, which I strongly suspect is the plant meant.—H. E. W.

Name of plant.—*J. M. K.*—*Saporaria officinalis* fl.-pl.

ORCHARD AND FRUIT GARDEN.

FRUIT BLOSSOM AND CROPS.

THE meagreness of our hardy fruit crops this year throughout the country is attributed to various causes by different growers. Some imagine that the late spring frosts are to blame, others that the cold, cutting winds, prevalent during the flowering period, are accountable for the mischief, while not a few remark on the alternate crops and failures occasioned by exhausted soil and the feeble vitality of the trees. All of these causes no doubt contributed in some degree to the failures or partial failures met with in different localities. The influence of frost on the flowers was next to nil in some neighbourhoods, whilst, perhaps, in colder and more moist situations its injurious effect would be manifested. The cold, cutting winds were, however, pretty evenly measured out to all in the island, and the bruising and otherwise damaging of the flowers, as well as the robbing them of their moisture, may be credited to their evil agency. With feeble health—a bad circulation—the badly nurtured trees would be in sorry plight to meet the excessive demand made upon them in the way of moisture, to supply the needs of the enormous wealth of bloom they were struggling to perfect. The neglected trees that only carry a crop about every second or third year are the ones which yield to inclement atmospheric forces the most readily. The exceptional amount of blossom, too, that the plants were bearing would materially aid in exhausting them of their manufactured or digested food, and be the means of still further impairing health and vitality. Besides the waste of the plants' food, occasioned by allowing the enormous quantity of useless blossom to develop, there is the excessive drain on the sap supply to be considered in relation to the well-being of the trees and crops. At this early time of the year the soil is cold and young roots are few, old ones are not active, and it is questionable if

the plant can supply the flowers with sufficient moisture to enable them, under favourable circumstances, to mature and set, even were the tree able to furnish the food-materials necessary for them to do so. In the absence of sufficient moisture to meet the demands of flowers and atmosphere, imperfect and weakened blossoms would be the result. This, combined with the complete exhaustion of the stored food of the previous year and the crippled health of the trees, renders the chances of a crop smaller. For, even although a fairly good set were secured, the vitality of the plant would be so weakened that the newly-formed fruits would drop off from want of support. The enormous wealth of blossom, then, looked at from this point of view, would be detrimental to the welfare of our fruit trees in feeble health. To remedy these evil effects we would either have to improve the health—circulation—or reduce the amount of work of the plant. The former can, in most cases, be accomplished by feeding, and the latter by thinning the buds. By the thinning of the flower-buds of old and not too robust Peach and Nectarine trees I have secured better health in the plants, and consequently heavier crops of much finer fruit than formerly obtained. By this process of conserving the plants' energy and concentrating it into a limited number of channels, we might be able to enhance the chances of our hardy fruit crops. Of course, with large standard trees of Apples, Pears, Plums, and Cherries, the operation of thinning the flower-buds would be a rather big undertaking, but with wall trees and those in bush and pyramidal forms on dwarfing stocks it would be a simple matter. It should only, however, be plants with impaired health that should be treated in this manner. Strong, vigorous ones, on the other hand, are benefited by being allowed to carry all their bloom, which, by the way, is usually sparsely distributed over the trees. Again, the thinning of the buds should not be uniform with all plants, but rather regulated to be in keeping with the vitality of each, thinning most

severely the trees with the weakest constitutions.

J. RIDDELL.

DRIED-UP ORCHARDS.

EVEN in the good fruit counties one may often see orchards starved from want of water, and the turf almost brown as the desert. That is the result of neglect in our dry summers. Where manure is plentiful it is well to use it as a mulch for such trees, but we write in the hope of calling attention to the unused materials at hand for keeping the roots of such trees safe from the effects of drought. Not only the tree roots want the water, but the roots of the grass, which is very apt to suck all the moisture out of the soil. The competition of the grass could be put an end to at once and the trees very much nourished by the use of a simple and easily found mulching from materials which are often plentiful and even sometimes do harm in a country place. Among the best of these, where plentiful, is the common Furze, if cut down in spring and placed over the ground round the base of the orchard trees. It would, in this way, prevent the grass from robbing the trees and let the water fall through the ground, helping to keep it there, too, by preventing direct evaporation; moreover, the small leaves falling will nourish the ground. So again the sweepings of drives and of the farm or garden yards are useful, and also any small faggots which are often allowed to rot in the woods after the underwood is cleared. They fetch such a low price that they are not worth selling, but such faggots if placed round the roots of fruit trees often do good. Then also there are the weeds and refuse of gardens of all kinds which form detestable rubbish heaps, that would be much better abolished, and all cleanings from the garden placed directly over the roots of orchard trees. There is so often an orchard near the garden, that this would generally be a handy way of getting rid of green rubbish, and if spread for a few feet on all sides about a tree would not only keep the grass in check, but the accumulation of such spare stuff year by year would promote healthy growth and good crops.

Even rank weeds, that swarm about yards and shrubberies, would help. We are often asked how to get rid of rank weeds of this sort, and one

of the best ways to weaken them and help towards their destruction is by mowing them down in the pride of their growth in the middle of summer—Nettles and Dock, as the case may be, and instead of burning them or taking them to the rubbish heap use them over the tree roots. Even the weeds growing round the base of the trees, if cut down and left on the ground, and at the same time some of the grass near thrown with them, will make a great difference in the growth and health of fruit trees.—*Fichtl.*

Fruit growing in Germany.—Wurtemberg grows more fruit than any other part of Germany. It contains over seven millions of fruit trees, which produce 60,000 tons of fruit, valued at £300,000. Notwithstanding this abundant produce, the Kingdom imports heavily, particularly Apples, which are converted into cider. In 1891 this importation was valued at £350,000. Throughout Southern Germany the culture of fruit is practised along with heavy agriculture, so that one commonly meets with fruit trees among the cornfields and meadows, as along the high roads. But in Northern and Central Germany this is not tolerated, and fruit is confined to the orchards and high roads. Germany exported in 1891 fresh fruit valued at £468,900, and imported Southern fruits to the value of £786,350.

NOTES AND QUESTIONS.—FRUIT.

Pine-apple Nectarine.—For flavour this Nectarine is difficult to beat. The only fault I know that it possesses is that of showing a tendency to shrivel just when ripening. Some of the best samples I have seen of, and these were absolutely free from shrivelling, were early this month at Aldenham Park. Mr. Beckett attributes his success with this variety and its perfect freedom from shrivelling to abundance of water at the roots during the ripening stages.—E. M.

Grape Duke of Buccleuch.—Some remarkably fine specimens of this handsome Grape were to be seen in one of the vineries at Ganton Park at the end of August. The bunches were not of exceptional size, but the berries were very large, and, what is more, they had put on that colour which is so desirable in this Grape, when seen in the best possible condition. To his success Mr. Allan attributes the application of shade to the glass just previous to the commencement of colouring. Certainly the appearance of the berries warranted the treatment received.—E. M.

STOVE AND GREENHOUSE.

CULTURE OF STEPHANOTIS.

THE note by "A. W." on this plant is interesting, for, as hinted, many growers are unaware that this fine climber is much more satisfactory in a fairly cool house than a stove. It makes shorter-jointed wood, flowers more freely, and keeps more free of insects than when given a lot of heat. Atmospheric moisture is necessary, but the house must not be over-heated. In the west of England I used to have under my charge a large plant that was trained over the roof of a span-roofed structure wherein Maiden-hair Ferns were grown for cutting. It covered the entire roof, the house being about 20 feet long by 10 feet wide. At that time the demand for cut Fern fronds in a deep green state was large, and consequently abundance of air night and day was allowed, the temperature at night in summer rarely exceeding 50°. The Stephanotis was planted in a brick pit, and only got one cleaning each year, while, owing to the Ferns being beneath it, the syringe could not be used so freely as was desirable. But the hard, solid shoots had always a bunch of flower at each joint, and very little mealy bug was present. Again, many growers use far too rich a soil for the plant. Good fibrous loam and peat in equal proportions, with a little dried cow manure rubbed up finely makes a good basis, and if a few lumps of charcoa are added this allows of the compost being rammed fairly firmly in the pots, the being conducive to

hard growth and thick leaves. This may seem rather a poor compost, but the flowers will set up much better in it than in a richer one, while it is easy to feed the plants a little while the flowers are forming. The roots are fairly strong and vigorous, yet they are easily damaged by over-watering, and this is an argument for pot culture rather than planting out. The roots are more under control, the air plays more freely about them, and they live longer. When the plants have filled all the available space annual pruning is necessary; it is wise even in the younger stages to take a little of the older wood out after flowering, but it is imperative with large, old plants. If left, the wood gets very thick in places, while much of the older growth will become bare of leaves. The Stephanotis is easily propagated, but the long cuttings sometimes used are quite unnecessary, not to say unsuitable. The best wood to use is the short, stubby side shoots with leaves about half an inch apart. These may be inserted about an inch deep in a light sandy compost, kept very moist and close for a little while, when every cutting will root, and may soon be grown into nice little plants.—H.

—The mention that has been made concerning this valued climber when given cool treatment reminds me of some capital plants I saw some years since in Cambridgeshire. These were planted out in a prepared hole beneath the path level of the floor, and the arrangements were such that only on very sharp nights was any heat turned on at all. The plants were trained to a brick wall, the house facing north and lean-to in character, but protected on the warmer side by a house of ferns, which of course materially assisted the climber. At the same time the actual temperature within the house was often very low, and but for the fact that no water was given at all during winter, the plants would have probably perished. The plants moreover remained perfectly healthy and vigorous, and flowered abundantly each year during summer with a regularity that became proverbial. It is just on this that the value or otherwise of growing such things depends. Of course such a system may justly be described as experimental rather than cultural, when for several months of the year no attempt is made to grow the plant at all. Many plants will with impunity endure a much lower temperature than that in which they are grown. But the chief question is, are such usually profuse flowering plants profitable so grown, or the reverse? To grow a surplus plant or two in the conservatory for a special purpose is, of course, another matter, and as such may be much more freely indulged in. All the same the gardener will not follow the cool system for those plants from which he expects a fair crop of winter bloom.—E. J.

FUCHSIAS.

To those who are fond of Fuchsias I would strongly recommend the practice of raising a batch from seed every year, for seedlings make well-shaped plants which are generally very free-flowering and useful, and, though the majority of them do not carry blooms of a quality that would entitle them to general distribution, all are sufficiently beautiful to admit of their being grown for a year or two at least, while now and then one finds a real gem. Such an one was raised here three years ago, a very dwarf grower, the original plant being only now about a foot high, and very bushy. It has a small flower, no larger than that of the old *F. Riccartoni*; the sepals are a bright red, and the tiny double corolla pure white. It is wonderfully free-flowering, and appears to have most of the attributes of a good bedding Fuchsia, but I have not yet tried it in this way as it has been so useful in small pots for vase work. Using seed supplied by a reliable firm, I have from time to time raised many really good things, and a large percentage has been varieties with white corollas and bright red tubes and sepals. These, whether single or double, are generally much appreciated. I also get a great variety in habit, and find plants suitable

for any form of training—some as climbers, others as trailers or basket plants, and others again that require no training of any description except the annual pruning which all Fuchsias more or less require. Fuchsias differ greatly in their requirements, especially as regards their winter treatment, and I believe that it is due to this fact that many of the handsomest species or varieties are not more often seen. Take, for instance, that lovely hybrid Earl of Beaconsfield. I find that if this is dried off during the winter in the way that suits most Fuchsias the plants seldom recover, and, if they do, they are very inferior to those that are kept moist enough to never entirely lose the whole of their leaves until pruned. *F. fulgens*, one of its parents, has the same attributes, and so, too, has *F. splendens*, among species, and others among the ordinary varieties that require a little special care to prevent over-drying through the winter could be named; indeed, any of those which are prone to dying out are best treated in this way and should be kept apart from the others. It is a good plan with these difficult varieties to strike some cuttings in August or September, keeping them growing all winter. Such cuttings make capital plants the next year, and provide against losses among older stock.

J. C. TALLACK.

MANURES FOR HYACINTHS.

WHEN a Hyacinth bulb is obtained in autumn from a salesman it is understood to contain embryo leaves and flower-spike, and sufficient food material to develop both with the aid of water. This supposition is annually verified by the many thousands of bulbs grown in glasses. Knowing this, the questions arise, Are fertilisers essential in the soil of those grown in pots, and, if so, why? Looked at casually we would be inclined to think fertilisers unnecessary, and, perhaps, when normal growth and blooms are the only aims of the cultivator, this is so, but if we wish exceptional spikes and abnormally large flowers we are forced to acknowledge otherwise. Again, besides merely developing the embryo leaves and flowers of the imported bulb, it might also be desired to have a supply of flowers from the same bulb for a number of consecutive years. By thus considering the objects we have in view, we are able to facilitate the result desired. In aiming at large flower-spikes, fine individual blooms and good colour, it will in most cases be necessary to add potash and phosphorus to the soil at potting time. One shovelful of wood-ashes, or 1 lb. of sulphate of potash, and 1 lb. mineral superphosphate to every barrow-load of soil, and well mixed a month before being used, will form an excellent compost so far as plant food constituents are concerned. If there should be any want of vitality in the plants—apparent by soft, flabby leaves, or the leaves curled over at their edges—then assistance will be indispensable in the form of a nitrogenous manure. The best form in which this can be supplied is nitrate of soda, at the rate of half an ounce to two gallons of water. Of course, nitrate of soda should be used with discriminating intelligence, for an excess will have a tendency to the production of large, soft leaves and a deficiency in the colouring of the flowers. But being a manure that can be withheld and applied at will—not remaining long in the soil—growth can be so regulated that all excesses can be guarded against by its rational use. Should the aim of the grower be to cultivate the Hyacinth bulb for a number of years, and have an annual crop of flowers from it, the leaves ought to be encouraged immediately the flower-spike is fully developed. This is done by increasing the available nitrogen in the soil. With a fortnight's treatment of an increased strength of nitrate of soda, a top-dressing of mineral superphosphate should be given, but only a light one. Repeat the application of phosphate every ten days, till the leaves show signs of ripening. This will enable the bulb to form another crop of leaves and flower, and lay up a store of food sufficient

for their normal development. Treated in this manner *re manures*, the same Hyacinth bulb continues to annually yield good spikes of large, well-coloured flowers, and proves that, even although cheap, it might be economy in some instances to grow the bulbs at home. J. RIDDELL.

TUBEROSSES.

THESE sweetly-scented flowers are always in brisk demand, and although the plants when in flower are rather lanky in appearance, they do well for grouping. The culture is simple in the extreme, and yet even when good bulbs are procured they are often a failure at the hands of amateur growers. It may be conceded at the first that without well ripened and heavy bulbs no culture, however good, will produce satisfactory results. When received, the bulbs must be thinly spread out in a cool, dry store, especially if they have to be kept for late work. The earliest batch should be potted in a size only just large enough to take them easily and allow of a little fine soil being placed around them—this because it will be necessary to push them into growth almost at once. It is usually the least satisfactory lot. Placed over a moderate heat the top growth soon begins to show, and the young leaves may grow about 4 inches high before giving a shift into 5-inch pots, these being quite large enough for forced bulbs. The roots will probably not have made much progress. If they have, so much the better, of course, as the spikes will ultimately be stronger. Water sparingly at the root and keep the atmosphere very moist and warm. For those required later, a better plan is to pot at once into the flowering size and stand the pots in a cool, dry house or shed, watering them once, allowing them to get a little dry, and then covering the pots with ashes. A single potting may be made to supply plants for forcing over a considerable season, as they may be drawn out as required and will be making root in the meantime. The latest batch must be kept out of the soil as long as possible, and when seen to be starting to grow, potted and brought on as slowly as possible in a cool house. In every case it is of the utmost importance that the atmosphere is kept moist and the plants looked over for insects occasionally. It is best to keep them out of fruit houses if possible, for no plant that is grown is more liable to be infested by red spider. This pest is doubtless imported with the bulbs in many cases, and is sure to attack the young foliage. If not taken in hand at once it will rapidly overrun the entire plant and prove an intolerable nuisance in the houses. I have tried sulphur on the bulbs before potting, but with no effect. The only thing to be done is to prevent the pest from spreading when it is first noticed; this is done by frequently syringing the plants with soft water and vaporising the house as often as convenient. The foliage is so tender that sponging, unless very carefully done, leads to damage.

The bulbs are usually furnished with a lot of small offsets, and these should be picked or cut off before potting, as if left they grow up all around the main stem and rob it of nutriment, often to the extent of preventing the main stem from developing, when the plant is, of course, useless. Owing to the amount of water the plants require, drainage should have special attention, and the crooks may be covered with a little rough leaf mould, Moss, or other material. They grow freely enough in a mixture of light sandy loam, well-decayed horse manure, and leaf-mould, with a good sprinkling of silver sand. A little of the sand may with advantage be placed around the base of the bulbs, and the soil should be finished with the top of the latter well out of it. For indoor decoration and grouping in the conservatory, it is often an advantage to have plants in the smallest possible sized pots. The spikes will not be so fine in these, but they will be very useful if the soil is kept moist from the time it is filled with roots and these are well fed from the surface. Any

good manure will do for this purpose, occasional waterings with soot-water being helpful to the foliage. R.

Rhododendrons in flower.—The different Japanese Rhododendrons are just now blooming freely; indeed, where a collection of them is grown, flowers more or less in number can be found nearly all the year round. This class of Rhododendrons is totally unlike any others, as they grow at all seasons, and as soon as a young shoot has reached its limit, a flower-bud is formed which soon develops and bears a cluster of blossoms. The reason of so many flowers being produced just now is that growth is more active in the spring and early summer than at any other time, and the shoots then made are just now bearing their blossoms or rapidly approaching that stage. Then, after the present crop of bloom, the autumn growth which will flower in the spring is developed. At the same time, though the greater number of new shoots is produced during these two periods, fresh growth is continually taking place; in fact, this class of Rhododendrons may be described as almost perpetual growing and perpetual flowering. They are certainly very beautiful subjects for the greenhouse at this season, though during the winter they need a structure kept at a somewhat higher temperature than an ordinary greenhouse. So free-flowering are some of the varieties, that it will be found absolutely necessary to remove the bloom-buds for a time to induce the plant to make more vigorous growth.—H. P.

THE MARKET GARDEN.

PLUMS IN KENT.

THOUGH Plums are widely grown in Kent, they do not claim their own districts as is the case with Currants, Gooseberries, Strawberries, Raspberries, and Cherries. Plum growing from a commercial point of view is neither confined to county nor locality, for in many favoured districts in the country Plums of all sorts are grown extensively for sale. Perhaps this has had the effect of making the crop a general rather than a special one in Kent, for in spite of the fact that many acres are devoted to the fruit, you do not find large areas confined alone to Plums, as is the case with Cherries and other fruits. In respect to Plums, Kent does not possess a monopoly to the same extent as is the case with some other fruits, and as growers in other counties also send large quantities to the markets, Kentish fruit farmers have found more profitable means of investing their capital by devoting their chief attention to other fruits which are produced principally in the county. London is the chief market for Kentish Plums, where the fruit is disposed of mainly for cooking and preserve-making. Some growers, however, living in the neighbourhood of the popular watering-places on the Kentish coast do better with both this and other fruit by disposing of it at these resorts than by sending it to the metropolis, where returns are ruled entirely by the state of the market, and the grower must be content with whatever the middleman sends him.

It must not be thought from the foregoing remarks that Plums do not form an important item in the profit and loss account of the Kentish fruit farmer. On the other hand, they do, and the condition of the Plum crop generally has a great bearing on the returns. In seasons of plenty, prices sometimes fall so low that the fruit hardly pays for gathering, and in times of scarcity the Plum has to make up for deficiencies in other directions. Last season, for instance, Plums and Damsons were both scarce, except on some plantations, and where growers were fortunate in having a moderate crop, prices ruled very high indeed. One grower in the Canterbury district informed me last season that he made more in comparison out of a dozen old Damson trees that he had contemplated cutting down than from any other portion of his farm. This year there will, I

think, be a different tale to tell. In some districts the fruit is thinly distributed, but in others, trees of the more common varieties are laden with fruit, and this cannot fail to have its effect on the markets.

In the cultivation of his fruit generally, the Kentish grower works on excellent principles. He is up to date in his methods, pays close attention to details, keeps a sharp look-out for good varieties for market, and, generally speaking, follows business lines. I could point to scores of mixed plantations, as well as Cherry and Apple orchards, that are splendid examples of cultural skill in face of the continual dismal cry that English fruit growers are all behindhand in their methods. Fruit growing is not the sure and certain means of making a fortune that some people would have us believe. There are a hundred difficulties in the way to be overcome which make it all the more creditable to those who do succeed. I think there is less attention devoted to the cultivation of Plums in the county, however, than is the case with other important crops. That Kent does not command a monopoly of the crop may be the reason, but if some of the best varieties were grown in preference to so many common, and consequently less valuable, sorts, there is every reason to think that the crop would be more profitable. There are hundreds of trees of Pershore and other common Plums grown along the sides of fruit plantations and even hop gardens simply for the sake of protection. They serve that purpose very well, and in favourable seasons bear heavy crops of fruit, but the quality is not good enough to command high prices, and, consequently, most of them are disposed of to the jam factors at a cheap rate.

The old Green Gage is a favourite Plum in Kent, and, taken all round, it is one of the most profitable. It generally fetches a good price. In recently-formed plantations some of the later additions to the Gage section are to be met with, but the old and well-tried sort is the most popular. Green Gage is always an uncertain cropper, and in some seasons a few bushels of fruit fetch more than treble the quantity when Gages are plentiful. Some of the finest Green Gage trees I have ever seen are in mixed plantations in the neighbourhood of the ancient port of Sandwich. The soil, which is deep and mellow, is well suited for fruit growing, and Plums do well. This season Green Gages are a good crop, but prices are only moderate. In some plantations Plums are grown as standards, Gooseberries occupying the space underneath. While the Plums are of moderate size the system pays well, but when the trees get so large as to check the bush fruit, the sooner the latter are removed and the ground turned into a permanent orchard the better, as the manure and labour required for the bush fruit are not counterbalanced by the crop.

The round half sieve is the principal receptacle in which Kentish Gages are despatched to the market. After being used for the small fruits, piles of hampers are returned to the plantations for the later fruits. It has often been suggested that money might be made out of Green Gages by packing the best fruits in dainty little boxes in the same manner as the quantities that come from France and are sold in fruiterers' shops. I do not know of any grower having tried the experiment, nor do I think it would be very profitable, for though English fruit growers may be excellent cultivators, dainty packing is not their forte. Their method is to produce in bulk and dispose in bulk, and if dainty packing such as is successfully practised on the Continent ever becomes common in this country, it will be done by people who will buy the fruit from growers, daintily pack it in various ways and then dispose of it. In this way there may be an opening for a new industry.

Victoria has proved one of the most valuable Plums in cultivation, and tons of this variety are annually despatched to London and other markets from various parts of Kent. It is frequently met with grown as bush trees in plantations in conjunction with Apples, small fruits being cultivated

between the rows. There is no need to dwell on the good qualities of this variety, which is so well known to everybody, and I have heard the opinion given by more than one grower that it is the most profitable Plum in cultivation. It crops well on most soils, but in the deep rich medium to be found in the best fruit-growing districts in Kent the fruit is fine and the flavour so delicious, that Kentish Victorias have few equals for dessert or any other purpose. The variety is a sure and free cropper, and owing to climatic advantages the fruit from this county is placed early in the market, to be followed by hardier and later sorts. Pond's Seedling is grown somewhat largely and is generally profitable. Good varieties of later introduction are becoming more widely cultivated by the most energetic growers. Early Prolific and The Czar have already made a name for themselves, and I have met with numbers of trees of these varieties in recently-formed plantations. Menarch is also being planted for a late crop. These do not include the whole of the varieties grown in Kent, as quantities of Cox's Emperor, Orleans, Jefferson's and other sorts are annually dispatched to the markets.

Sharp frosts and attacks of blight are among the troubles of Plum growers, the former being the worst in low situations. This season has been a bad one for aphides, and in the early part of the summer the trees in many places presented a pitiable appearance. In spite of this, however, the crop is good in most districts and heavy in some, and the tropical weather experienced during August and September has caused the fruit to ripen early, which means that the Plum season will be shorter than usual. The cultivation of the best varieties of Plums appears to be on the increase on Kentish fruit farms, but there is no doubt that the presence of so many of the common heavy cropping but inferior sorts is the means of keeping prices down and checking the spread of cultivation of high-class varieties. Owing to the quantities that are grown for sale in other counties, Plums cannot be classed amongst the most important of Kentish crops; still, growers know the wisdom of not having all their eggs in one basket, and so long as the demand for them exists, Plums will be found on Kentish fruit plantations. G. H. H.

ORCHIDS.

COOL-HOUSE ORCHIDS.

ALTHOUGH as I write the heat is intense, it must be only the question of a week or two before we get a change, and as soon as the first drop in the temperature occurs a start must be made with the earliest of the cool-house species. A thorough overhauling is usually necessary, cleaning and repotting or surfacing, as may be required, and rearranging for the winter. Repotting is of course the most important detail, a good deal depending upon how it is carried out. Wherever it is possible catch the plants when the growths are about half made up, this being the case now with a great many of the *O. crispum*, *O. Pescatorei*, *O. luteo-purpureum*, *O. Halli* and *O. triumphans* varieties. I have often noticed that disturbance of the roots of certain plants predisposes them to new root-action, and in the case of healthy specimens, so far from doing any harm, does a great deal of good. The new roots come away quickly, take hold of the new compost, and ensure the making up of a fine pseudo-bulb before we begin to look for spikes, while the spikes produced from bulbs well developed are in most cases finer and certainly distress the plants less than others that appear upon a half-finished bulb. The energies of the plant in the one case are entirely devoted to the flower-spike, while in the other they are divided,

so to speak, between it and the growth. Exceptions there may be, of course, but this I have found the rule. The great thing then is to stimulate root-action, and this in the case of the plants under notice cannot be done by exciting temperatures or anything of this kind. These will in fact hinder the end in view, for it is impossible to force a cool-house Orchid.

A far better plan is to keep up a very moist atmosphere in the immediate neighbourhood of the roots by damping freely about the pots, keeping the compost itself a little on the dry side both before and after repotting. I am speaking of healthy, well-rooted plants, of course. As regards the manner of potting and material used, these have been frequently noted, and it is only necessary to say that the pots or baskets used should not be too large. Peat and Sphagnum Moss are the best ingredients, and these should be held in an open condition by adding freely crocks and charcoal. Let everything used be thoroughly clean, and ensure a quick passage for water by plenty of drainage material. It will be noticed, too, that different species have roots of varying size; the small, twining roots of the *Odontogloss* referred to are quite distinct from those of the Guatemalan *O. grande*, and the cool section of *Oncidium*s, such as *O. macranthum*, *O. serratum*, *O. undulatum* and others of this class. No hard and fast rule can be made, and no nice distinction laid down, but as a general rule the larger the roots are the rougher the compost and the larger the receptacle for them. It will also be noted that in a great many instances the larger the roots, the greater percentage of Sphagnum Moss is liked by them. Where plants need to be surfaced only, and not repotted, these should, if convenient, be placed by themselves afterwards, as the treatment as regards watering will be slightly different, and it is not easy to distinguish one from the other when the surface compost of both is new. The latter plants have a lot of attached feeding roots that the disturbance has not left the others, and these will therefore need more moisture. A surface damping often does good to a newly-potted plant by encouraging the roots; to one surfaced only it would not be so helpful, as the lower and most active roots would not obtain any benefit therefrom. A thorough cleansing of the house and stages is necessary when repotting is in progress. The material used for staging on such as shingle, spar, or coke may be turned to do away with the slimy growth that is almost sure to be present after a season of growth with its attendant dampings. Walls, wood, and glasswork will probably all need attention, and any plants not repotted should have their pots scrubbed. The growth of *Tradescantias* and similar plants about Orchid stages is not to be recommended by any means, but where these plants are used the present is a good time to thin the growth a little where necessary. On very damp walls one or two of the species of *Pothos* may be used with good effect and without any fear of introducing insects, but the less of this class of thing that is carried on in Orchid houses the better. Shading is an important detail after repotting; it may almost be said that the plants cannot have too much shade, but this is only true as long as the weather remains bright. In dull or showery weather great care must be exercised, for every ray of light is of advantage to the finishing growths, yet a few minutes' bright sunshine will often mean the disfigurement of much of the foliage. Weak and badly-rooted plants must have the shadiest place, while any that have not been repotted may have the most light. Keep the dwarf kinds, as *Odontoglossum Cer-*

vantesi, nearest the glass, and arrange the largest growers on the central stages. H.

Aerides suavissimum.—When seen in good condition and well flowered this is one of the noblest of Orchids. It is, perhaps, oftener met with under the name of *A. nobile*, and is a tall-growing, handsome plant even when out of bloom, while the lovely racemes, each 18 inches or more in length, crowded with the fine showy flowers, are superior to those of such species as *A. odoratum*. It grows very rapidly in a warm, moist house and delights in plenty of sunlight, only avoiding injury to the foliage. I used to have this species in large baskets 2 feet square, and the plants about a yard through: in this state it produces a large number of spikes, which last well in good condition at a time Orchids are scarce. Such a free-growing plant naturally requires ample room for its roots, and this is where many growers go wrong with it. Small side growths may with advantage go into baskets or pans that can be suspended from the roof, but when they begin to get larger a flat basket or large pot on the stage is a better place for them. It is, if anything, easier to grow than an ordinary *A. odoratum*, putting on more leaves in a season and producing side breaks with greater freedom. *A. suavissimum* is a variable plant in the colour of its blossoms, but the usual tint is white, more or less suffused with rosy purple and lilac.—H.

Laelio-Cattleya corbeillensis.—This is a hybrid of continental origin. It is the result of a cross between *Cattleya Loddigesi* and *L. pumila*, the same cross that had previously produced *L.-C. Aurera* in this country, and it can only be considered an inferior variety of that hybrid. The sepals and petals are deep rose, of good form and substance, but the size and colour of the front lobe of the lip are not so fine as in the English raised hybrid. This front lobe is fringed with rich crimson-purple, with a light rose-purple dash in the centre. The side lobes are pale rose, shading to white, with some yellow at the base. The flowers are produced oftentimes three and four on the spike, this depending considerably on the strength of the plant. In growth it has the intermediate characters of both parents. It does best under cool intermediate house treatment, that is, a temperature a few degrees warmer in winter than the *Odontoglossum* house. *L.-C. blessensis* is also said to be derived from the same parentage. Here a mistake has evidently been made. This hybrid has the characteristic markings through the throat and front lobe of the lip as seen in *Laelia pumila Dayana*, but with this exception there is little variation between the three hybrids mentioned above.—H. C.

Warszewiczella Wendlandi.—This is one of the most attractive species in the genus, and I noted an extra fine variety of it in flower recently. The leaves are about 8 inches in length and the flowers quite 4 inches across. These are pure white on the sepals and petals, the pretty ruff-like lip being white, the centre purple. The plant does well in an intermediate temperature, and it is important that the moisture be kept well up during the growing season, otherwise the growth is sure to be over-run with thrips or red spider, and this ruins their health. Root moisture, too, when the roots have obtained a proper hold on the compost must be very abundant, and even during the winter or resting season the roots must never be quite dry for any length of time. The roots are rather large and fleshy in texture, liking a rough, open mixture of clean Sphagnum Moss and peat, many growers using a portion of loam for strong plants. Their position in the house must be rather a shady one, the leaves being easily injured by sunshine, though liking a fair amount of light. Grown under these conditions the plants will flower freely, but given too much heat they sometimes grow all the year round without flowering. Besides the above-named insects scale is often troublesome, and soon spoils the tender foliage if not taken in hand and destroyed as soon as seen.—H.

DENDROBIUM DEAREI.

This is one of the most useful Orchids in cultivation. Being in bloom during the summer and early autumn months when other flowers are scarce adds considerably to its value. This, combined with its value for cutting and the durability of the blooms where it is desirable to keep the flowers on the plants, should give it a place in every collection. I have had plants in flower here in London since the beginning of July. Notwithstanding the excessive heat of the present season, the flowers are still in perfect condition, and I have known instances in which blooms have been removed in good condition three months after they have expanded.

D. Dearei, a native of the Philippine Islands, was discovered and introduced by Colonel Deare in 1882. Shortly after it was imported

or charcoal, which assists in keeping the material in an open and porous condition. As the plants require a liberal supply of moisture at the roots during the greater part of the year, this should not be overlooked. Black thrips, red spider, and scale are the most dangerous insect pests. Occasional fumigation and sponging will be necessary to keep the plants in a clean and healthy condition.

The accompanying illustration represents a plant of this lovely species that was exhibited at the Drill Hall meeting of the Royal Horticultural Society on July 12 last by Mr. H. Hicks, Branwood, Chelmsford, who has kindly sent the photograph. The plant was awarded a silver Banksian medal by the Orchid committee on that occasion. It is undoubtedly the finest specimen that has been seen. The plant

tion in an intermediate house, a rough compact and abundance of water while growing. During the resting season keep the plants quite cool and dry, but avoid shrivelling of the bulbs. Unless so treated the flower-spikes will be few. It is a native of Peru, and was introduced about 1838.

Mormodes pardinum. The flowers of this singular species appear at various times through the year. I have noted it in several collections quite recently, yet it quite as often flowers in the spring months. Beautiful as these species are, they do not seem to take the fancy of growers now-a-days. The culture of the plant is not difficult so long as healthy specimens are procured, but once let them get badly out of health and they are difficult indeed to restore. The flowers, which appear on arched spikes, are bright yellow, spotted with red, the variety unicolor being wholly yellow. A brisk moist heat while grow-

Dendrobium Dearei. From a photograph sent by Mr. H. Hicks, Branwood, Chelmsford.

in quantity by Messrs. J. Veitch and Sons through their collector, David Burke. It may be faithfully termed a perpetual grower, and requires a light position in the stove or Phalanopsis house, where it can obtain an abundance of heat and moisture at all seasons. The root moisture through the dull winter months must be carefully attended to to avoid stagnation, or the consequences will be disastrous, causing the points of the leaves to decay, and perhaps the ultimate destruction of the plants. I find the plants do best grown in baskets and suspended near the roof-glass. The baskets must be carefully drained with clean broken crocks, the potting compost consisting of good fibrous peat and living Sphagnum Moss, to which may be added a free sprinkling of finely broken crocks

had eleven flowering growths and thirteen expanded spikes of bloom, several others being in bud. Many of the bulbs measured upwards of 3 feet in length. The plant had been grown in an ordinary stove, standing on the stage amidst Crotons, Dracenas, and other stove plants. This fact illustrates the heat and moisture-loving characteristics of the plant.

H. J. C.

Oncidium aurosum.—The flowers of this species are very distinct and handsome, and I was glad to see a fine plant of it in full flower recently. It belongs to the yellow-flowered section, the spikes on well-grown plants often being considerably over a yard in length. The plant is not difficult to grow, and likes a light, airy posi-

ing and a thorough rest afterwards are essential.—H. E.

Cattleya aurea.—Some fine varieties of this beautiful Orchid are already open, and it well deserves its almost universal popularity. Small plants grown quite up to the roof-glass in a warm house are blooming very freely, only a few flowers being open, but every sheath is well filled. There is not a finer bit of colouring among the Orchids flowering now than the lip of this one, the lovely golden lines on the deep colour of the lip being magnificent. The plants must after this be kept at rest if possible, better growth being made in summer than winter.

Cœlia macrostachya.—The spikes of pretty rose-tinted blossoms produced by this plant make it worth growing where there is plenty of room, though it cannot be described as a first rate

Orchid. They appear at the base of the last-formed growth and take a long time to develop and open the flowers. It does not need great heat, but must have large, well-drained pots and a rough, open compost. Water very freely when in active growth, but when the bulbs are quite finished keep it drier in quite a cool house, or but few flowers will be produced. It is a native of Mexico and was introduced about 1841.

Dendrobium speciosissimum.—I have on several occasions noticed plants of this species doing very poorly, though others of the same section were thriving in the same house. Yet if it can be induced to grow strongly it is a fine thing, the pure white of the sepals and petals being well shown up by the deep orange-red of the centre of the lip. The blossoms on weak plants have the bad habit of remaining half closed, and do not therefore show their full beauty, but this should not be the case on well-grown specimens. It is found growing naturally at considerable elevation, I believe, and consequently will do with less heat than *D. formosum* and its allies.—H. R.

Epidendrum polybulbon.—This is a dwarf species, bearing freely the pretty little yellow and white blossoms. These occur singly on the scapes, which are only an inch or two in height. It does well in a warm or intermediate house if care is given, but being very small it is easily injured by checks owing to too little moisture in the atmosphere or from draughts. The plants may be grown in small pans or baskets, or even on trellised rafts, in each case requiring a medium thickness of compost only. Frequent top-dressing is preferable to disturbing the roots, and serves to keep the compost in a sweet and open condition. *E. polybulbon* is a native of various of the West Indian Islands, and was introduced in 1842.

VANDA HOOKERIANA.

This beautiful *Vanda* should be grown by all who have a suitable house for it, and many who do not grow Orchids at all may cultivate it easily in such places as Pine stoves or ordinary plant stoves where strong heat and abundant moisture are accompanied by ample sunlight. A house devoted principally to *Crotons* would, if the wants of these were properly catered for, suit this *Vanda* perfectly. The bright sun needed to bring out the colours of the *Crotons* to the full would be very like the conditions that obtain in its Bornean habitat, while the moisture would have to be ample to keep insects in check. The growth of this species must not only be very rapid; it must be hard and well ripened as it is made, or no flowers will be produced. The habit of the plant is scrambling and the roots are formed at short distances apart all the way up the stem, like those of a *Renanthera*. For this reason something should be provided that these can lay hold of as they are made, or a great deal of the strength of the plant will be lost. If pieces of Tree Fern stem can be had, they may be used with every prospect of success; but these are not always procurable, and a very fair substitute is a piece of Birch lightly dressed with Sphagnum Moss, this being fixed with fine copper wire. These pieces may be placed with the lower ends in large pots nearly filled with drainage, the upper couple of inches being made up of Sphagnum and rough charcoal. The lower tiers of roots will enter this and materially strengthen the plant. The pots should not be less than 9 inches across, or they dry up too rapidly and are very apt to fall about owing to the weight on top. Until the roots begin to run freely in the Moss this should only be kept just moist enough to keep it alive, but when this occurs the whole plant may be frequently dipped into a tank or tub, syringed frequently, or otherwise kept constantly and regularly moist as long as growth is active and the weather is bright. In this way the natural conditions under which it grows are imitated, and if an ammoniated atmosphere can be provided so much the better. The flowers of *V. Hookeriana* are produced on peduncles near the top of the plants, usually about three or

each, though more on a spike is not uncommon. The sepals are nearly pure white, the petals flushed and spotted with purple, the lip very much deeper, especially on the small side lobes, and also spotted with purple. Though described by Sir W. J. Hooker as long ago as 1856, this species was only introduced to this country alive as recently as 1879, and it first flowered at Tring in 1882.

ORCHIDS NOW-A-DAYS.

THE Orchid plants which one sees at the present day bear but a very poor comparison as to size with those which used to be found in collections a quarter of a century ago, and I think the scrappy pieces now so generally seen lose a great deal of interest, except perhaps to the Orchid specialist, who concerns himself with infinitesimal variations of colouring that have no meaning to the laity, and sees no charm in a big specimen further than to calculate into how many pieces it may be divided and how much it will fetch in the market. Not long ago I was shown a small *Cattleya*, a new variety, with more words in its name than there were leaves on the plant. A very high price was fixed to this particular specimen, though there are many more beautiful *Cattleyas* in existence, and before I left the place the so-called plant had been divided, so that it must be years before anything like a good specimen can be found; probably it never will be if the present taste for scraps of plants remains. When looking through collections of Orchids I miss the fine old specimens with their charming quaintness of growth and plenitude of aerial roots which helped one to fancy them as they grow in their native habitats. Of course, variety has been greatly increased during the period over which my memory takes me, and no one could deny the progress which has been made in that way.

Equally, of course, propagation must be effected to supply the demand for the best, but, leaving trade collections out of the question, Orchid houses in private places do not strike one as being nearly so interesting or their occupants so beautiful as they were a couple of decades ago. Having this in mind, it was especially pleasant to meet with a few really fine specimen Orchids recently at Coldham Hall, near Bury St. Edmunds. A fine plant of a good form of *Celogyne cristata* measured over 3 feet in diameter, and other big specimens were seen of *Cymbidium giganteum* showing well for flower, *Laelia superbiens*, *Angraecum eburneum* var. *superbum*, that will presently be carrying a great number of flowers, and *Cattleya gigas*, a large plant in good health and vigour. Such plants as these and big specimens of *Aerides*, *Vandas*, *Odontoglossa*, *Oncidium* and *Dendrobium* give houses a well-furnished and pleasing appearance that cannot be got from the scrappy pieces which one is now so accustomed to see. L. T. G.

Cattleya bicolor marginata.—This is very beautiful when first open, the bright colouring being much finer than later. The sepals and petals are quite an emerald-green, the lip bright crimson-maroon with a pure white border, and, though this makes the specific name unsuitable, it is a beautiful combination. The column of this species is not enfolded by the side lobes of the lip, as is usual in the genus. The plant is of fairly easy culture, but dislikes a strong heat, this leading to weak, spindly growth. Large plants may be grown in pots about 10 inches across, the compost being made very rough and perfect drainage given.

Laelia elegans (*R. Somerset*).—This is an average form of the section called *Schilleriana*,

the plants of which are generally supposed to have originated from a cross between *Laelia purpurata* and *Cattleya intermedia* in a wild state, other forms having without a doubt originated from the *Laelia* and *C. guttata*. It is a very useful garden Orchid and easily grown, flowering over a long season and lasting well in good condition. Wherever such species as those named above, *Laelia crispa*, or any in this section thrive, *L. elegans* will usually be satisfactory. The compost and general treatment are the same as for the labiate *Cattleyas*.

Miltonia spectabilis Moreliana.—A fine form of this pretty species comes from "C. C." for a name. It is one of the finest of autumn-flowering Orchids, and not difficult to grow if given reasonable attention. The plant has always a yellowish tint about it, but this is not necessarily a mark of ill-health. It likes a medium thickness of compost only, and may be grown on rafts lightly dressed, or in baskets two-thirds filled with drainage, the rest made up of peat and Moss. Water very freely during summer, and in winter allow sufficient moisture to prevent shrivelling. Give it a light position in the intermediate house.

Cymbidium Mastersi.—Although not so showy as some of the long-spiked species, this makes a pleasing change from such as *C. Lowianum*. The blossoms occur on sheathed spikes and are sweetly scented, white, with a few purple spots. High up on the Khasia Hills this species is doubtless often exposed to a very low temperature, and under cultivation it will be found to do well in quite a cool house. The roots are strong and the growth very free, so plenty of water and a rather rich compost must be allowed, no dry resting season being required, though during the winter far less water is needed than when hot and dry weather, combined with the free growth of the plant, makes almost constant attention necessary.

Cattleya Eros (*C. Mossie* × *C. Walkeriana*).—This is a distinct and desirable hybrid, the sepals and petals of fine form and substance, the colour being delicate rose similar to that seen in *C. Walkeriana*; the open and flat-shaped lip pale rose, covered with a suffusion of bright rose-purple, with some yellow at the base; the side lobes rose, shading to white at the base. The habit of growth is fairly intermediate, but resembles that of *C. Walkeriana* in shape, enlarged by the influence of the stronger parent. The leaf resembles that of *C. Mossie*. A plant with a single flower was recently exhibited at the Drill Hall from the nurseries of Messrs. J. Veitch and Sons, King's Road, Chelsea.—H. J. C.

Cattleya Harrisoniæ.—There is considerable confusion between this species and *C. Loddigesi* in gardens. In structure the flowers are similar, except the front lobe of the lip, which is not so deeply cut and is flatter, without the pinched-up appearance of the last-named species that is found in the former. It has also usually more substance in the flower. The variety *C. Harrisoniæ violacea* is a highly coloured form of that variety. It is scarce, and, being much sought after, usually realises fair prices. The imported plants sold as this variety cannot be relied upon, and do not as a rule turn out anything but the typical forms; at the same time there is always the possibility of flowering the dark forms and unique varieties from importations of plants, which, as a rule, sell very moderately, and can be procured for a few shillings. It also gives the amateur more interest in watching the development of his plants as they become established, and adds to his satisfaction should anything out of the common make its appearance. Both *C. Loddigesi* and *C. Harrisoniæ* flower during the autumn months of the year as a season when very few other *Cattleyas* are to be found in bloom. The flowers last a long time in perfection, and, not being too large, are useful for cutting. This consideration should add to the charm of this delicately tinted and useful *Cattleya*.—H. J. C.

FLOWER GARDEN.

NARCISSUS NELSONI VARS.

The varieties of *Narcissus Nelsoni*, even if less bold and striking at the first glance, are by no

Narcissus Nelsoni major. From a photograph by Mr. A. Dashwood-Howard, M.D., Hampton Hill.

means without interest and certainly not without beauty even amid so much that is beautiful in the genus as a whole. Indeed, so far as beauty with chasteness is concerned, I regard *N. Nelsoni major* as among the most pleasing for small glasses in a cut state. The accompanying picture will convey an excellent idea of the variety mentioned in this respect, and the drooping character of the blooms, so well shown, renders it very distinct among these hardy flowers of spring. So beautiful is it when grown in pots that it is sure to attract attention from almost anyone seeing it for the first time. It may not, perhaps, be considered an ideal flower for the market grower just because of its size alone, but the market grower is by no means an all-in-all authority on the subject of general gardening or even decorative gardening. I say so much because such as the above-mentioned kinds do not appear to be so generally cultivated as one may expect, and seeing there is a run upon the so-called market favourites. For the private gardener I consider the major form of *N. Nelsoni* one of the gems for cutting, and when pot-grown the segments of the perianth are singularly pure and chaste-looking. There is also considerable distinctness in the long, cylindrical crown that outside the few varieties of the group under notice is by no means common. Apart from these considerations, the quality of the flower is good; in fact, few flowers are superior to it in this respect. Happily, too, with all these good points the kind is comparatively cheap, so that it may be grown freely by those who so desire.

The varieties of this group, by their singularly graceful form, are specially suited for the rock garden in slightly raised positions where they may catch the eye. In this way they are very pleasing and attractive, and not less so in

a general way; or, again, in grassy spots, for here they produce an almost unique effect. Very few, perhaps, have adopted the combination of planting this and the well known Queen of Spain either as a mixed bedding arrangement or in grass. The Queen of Spain is a justly popular kind for bedding, and for all practical purposes *N. Nelsoni major* may be regarded as a bicolor of the same group. The stature of the two, as also the general aspect, has much in common, though the foliage is distinctly broader in the *Nelsoni* kind. They are all easily grown in light loamy soils, and need not be disturbed each year. The kind in the photograph will speak for itself, except that the segments are very pure and clear. *N. Nelsoni aurantius* has the cup slightly more expanded and rather shorter than in the above, and stained with orange-red at the tip. The variety *minor* is all the name implies, a dwarf and very pretty form, excellent for rock-work planting. *N. N. pulchellus* is a great beauty in this set, the perianth very white and well imbricated. William Backhouse is also a very beautiful form, with clear yellow cup and broad white perianth segments. These are all well worth growing, and, if not a very numerous company, may safely be regarded as among the most exquisite and pleasing — albeit modest and unassuming in general appearance — of this extensive and varied group of hardy bulbous flowers.

Cutting down the white Rocket.—Some time ago several notes appeared in THE GARDEN about this fine border plant. I do not remember seeing any mention made regarding cutting down the flower-stems. I am convinced that in many cases this Rocket and many other hardy plants suffer considerably from cutting the flower-stems off close to the ground as soon as the plant is out of bloom. Often at this stage no young shoots are appearing and hardly a leaf. I always allow the flower-stems to remain till the young growth for next year is well advanced.—DORSET.

The cardinal Lobelias.—Many years ago certain forms of the larger scarlet Lobelia were raised, and they were very popular at one time; but the great wave of bedding excitement put them into the background, and this notwithstanding that they were among the handsomest plants ever introduced to our country. Now we see a revival of interest in them and some attempts made to improve them. As regards the varieties like Queen Victoria that is impossible. MM. Rivière, of Lyons, have raised some handsome hybrids between the blue Lobelia of the American river banks (*siphilitica*) and the large scarlet Lobelias, some of which are pretty in colour and likely to be useful. *L. cardinalis* is smaller than the scarlet Lobelia and is distinct in colour; in fact, a distinct species. The hybrids with the blue

Lobelia have not seemed to us real improvements, but some of those raised at Lyons are much better than the old ones. The true cardinal flower is a good hardy perennial, and is a native of the northern and eastern States of America, growing in moist soils; but the plant that gives us the finest and most showy garden varieties is *Lobelia fulgens*, which is a native of Mexico and the Southern States. Although the plant grows well in summer in our gardens, it is somewhat tender in winter. We mean the varieties of this greater scarlet Lobelia. Round the coast, in light peaty soils, in the west country and in Ireland it often lives over the winter, but in inland districts and cool soils it must be kept in frames, as out-of-doors it is very apt to perish in winter. Firefly is among the best forms of this Lobelia. Distinction, too, is also good, and also Lord Ardlann, though too dark in hue for good effect. These have been sent us by Mr. T. Smith, of the Nurseries, Newry, and Firefly is the best of them.—FALL.

CROCOSMIA IMPERIALIS.

PROBABLY owing to the dry weather we have experienced of late, the blossoms of this beautiful bulbous plant appear even more brilliantly coloured than in previous years, and a mass of it has been for the last fortnight and still continues to be a particularly attractive feature in the garden. Whether the generic name of *Crococsmia* or *Tritonia* be the correct one matters little, but it was distributed and is more generally grown as a *Crococsmia*, though our botanical authorities include it in the genus *Tritonia*. It is nearly related to the garden forms of *Montbretia*, but is altogether a bolder-growing plant, with larger flowers. The branching spikes reach a height of a yard or more, while the individual blooms are on strong plants fully 3 inches across, of a brilliant reddish orange on the outside, and a good deal lighter within. As the blossoms have rather a drooping tendency, the rich-coloured exterior is more in evidence than the inside of the flower. Like the *Montbretias*, this *Crococsmia* is hardy in well-drained soils, but it is seen at its best where somewhat sheltered, such as a border in front of

Narcissus Grande. From a photograph sent by Mr. A. Dashwood-Howard, M.D., Hampton Hill. (See p. 211.)

a hothouse, under which conditions so many other South African bulbs flourish. *Crococsmia imperi-*

alis does not increase so rapidly as some of its allies, but it cannot be regarded as backward in this respect. The bulbs, which are about the size of those of a Crocus, push out stoloniferous stems that often travel some distance before making their appearance above ground. From this circumstance they soon take possession of a considerable space of the border in which they are planted, and if in pots these shoots take a circular direction, and continue in this way before coming up just at the edge of the pot. Like many other natives of the same region, this can scarcely be considered perfectly hardy, hence a little protection in the shape of dried leaves or some such material may be laid over the border during the winter in order to make all safe. Like the Montbretias, the leaves are particularly susceptible to the attacks of red spider, and frequently turn yellow before the flowers develop. When this occurs it detracts from the beauty of the plant, and in order to combat it as far as possible it must not be allowed to suffer from want of water. This Crocosmia may also be readily grown in pots and employed for the embellishment of the greenhouse or conservatory at this season, but when intended for this purpose the plants should be left out of doors till the flowers are just on the point of expanding, as in this way they are far more richly coloured than if taken under glass some time previously. H. P.

THE HYBRID CLEMATISES.

(Continued from page 201.)

I now go on to speak of the hybrids. The number of hybrids, almost all of them of the large-flowered kinds, is so considerable, that it would be difficult, not to say impossible, to enumerate them in their entirety. I am going to give a list of the best, grouping them to the best of my ability. I will commence with a description of two kinds which I have raised from seed.

Two hybrid Clematises not yet brought out are C. Marie Madeleine and C. Marie Louise.

C. MARIE MADELEINE.—The stem rises some 12 feet or 15 feet, as in the type, the leaves also like those of the type, but of a lighter green; flowers of the size of those of C. Jackmani, but in colour mauve, changing to violet-purple in the open flower, and afterwards to a brighter tint. This Clematis is closely allied to C. modesta (Viticella modesta, Hort.). It flowered for the first time in 1879. Its effect would be improved by mingling its bright gay tint with the more or less deep violet-blues or violet-purples (almost black) of other hybrids of the same race.

C. MARIE LOUISE.—Although summer-blooming, I, nevertheless, place this among the azureæ rather than the lanuginosæ. It is one of the handsomest I know, owing to the enormous size of its white flowers. The stems are ruddy and fluted, resembling in this the azureæ, but they are stronger, and may rise to a height of 6 feet or more. The leaves are a deep green, 3 inches to 4 inches in length by 1½ inches to 2 inches in breadth, and are lightly covered with down on the under side. The flowers are each 8 inches to 10 inches in diameter and well displayed; the sepals are narrow at the base and about 2 inches to 3 inches wide. They are pointed, smooth, and so light as to be easily stirred by the slightest breeze. The freshly-opened flowers are white with a pale tint of lilac-blue, which changes to a pure and shining white. Blooming commences about May 25, and is over about the end of June.

These two hybrids were produced spontaneously in 1875 or 1876 along a high wall which faced the west and was covered with a number of species of Clematis, notably azurea and a strong plant of Jackman's Clematis. In a neighbouring garden on a palissade facing north Clematis lanuginosa and florida venosa flourished in abundance. In December, 1877, my two hybrids, then young plants, were trans-

ferred to my new dwelling in the Avenue de Paris, and here they grew and flowered, as I have already described.

The hybrid and generally large-flowering Clematises should belong to one or other of the following five sections: 1, the Viticellæ; 2, the Jackmani; 3, the Floridae; 4, the Azureæ; 5, the Lanuginosæ.

I.—VITICELLE.

In this place my special purpose is to consider the Viticellæ proper, a very natural group, characterised by their racemes of cross-shaped, medium-sized flowers. They are summer-blooming plants. In describing the species

C. VITICELLA, I mentioned the fixed and oldest known varieties, viz., C. Viticella purpurea rubra, violacea alba, and fl.-pleno. To these should be added the following hybrids:—

C. RUBRA GRANDIFLORA (Jackman).—The flowers of this are of a good size and of a fine dark purple colour; the sepals are slightly twisted (sometimes partly green) and foliaceous.

C. KERMESINA (Lemoine).—A deep carmine, shot with flame colour.

C. IRIS.—The flowers, which have large sepals, are of a vinous-purple colour.

C. MME. MOSER.—In this the flowers are of a fair size and white, resembling in appearance those of C. Viticella Iris.

C. ALBA NOVA.—A distinct and old variety, the flowers white and composed of four to five petals. In

C. MONS. GRANDEAU the flowers are of a rose colour.

All the above four hybrids, of which one was produced from the seed of florida venosa, or at least the three first-named, have an evident relationship in the conformation of their flowers with Clematis florida or the hybrid f. venosa, to which C. Viticella Iris is allied.

C. ERECTA.—This Viticella, which stands about 20 inches high, is a hybrid, with larger deep blue flowers than C. nana.

C. FRANCFURTENSIS (Ruiz).—This Clematis I have had in cultivation over twenty-five years. It is a tall C. Viticella with handsome blue flowers, which are larger than those of cerulea. According to M. Lavallée, the Frankfort Clematis is a hybrid of Viticella × hakonensis, or Jackmani, like

C. GUASCO.—Obtained at Luxembourg by M. Guasco. It resembles the preceding.

C. OTHELLO (Cripps) is a medium-sized flower of a deep purple velvet colour.

C. RUBRA GRANDIFLORA NOVA (Flon).—For some months I have had in cultivation a variety of the red Viticella which was produced from seed by M. Flon, of Angers, and is still unnamed. This new acquisition I saw in full bloom in June, and it appeared to me very promising. It is a red Viticella, with flowers of fair size and well formed, allied to Viticella rubra grandiflora, which has already been turned to good account in the production of hybrids.

The other hybrids of C. Viticella are large-flowered Clematises, which must be classed with C. Jackmani. They are very numerous and compose the handsome red hybrids which are in so much request now-a-days. Before coming to them, however, let me mention several hybrids which are among the other types of this great section. Among the integrifoliæ,

C. INTEGRIFOLIA DERANDI, the result of crossing C. lanuginosa and C. integrifolia, is a handsome flower of a deep violet-velvet colour with yellow stamens. It is composed of from four to five sepals, each 3 inches to 4 inches in length, and remains in bloom from May to October.

C. HENDERSONI, of which I have spoken, is itself a true integrifolia; it is subfrutescent, and 5 feet to 7 feet in height.

The urnigeræ, whose pitcher form and original shape are especially noticeable in C.

Pitcheri and coccinea, have been hybridised, and three or four varieties have been raised by M. Louis Paillet, of Chatenay (Seine).

2.—THE JACKMANI OR LARGE-FLOWERED VITICELLE.

There are two distinct forms of Jackmani: that of the Viticellæ just described and an erect form characterised by tufts of flowers and by the axillary pedicels being ramified and many-flowered, and in the form of cymes. This second form is earlier than the ordinary form. This year, at a height of 10 feet to 13 feet, it gave me a magnificent and long-continued bloom, the flowers being large and for the most part having four sepals. I think the name of C. Jackmani splendida would be a good one for this. The type of Jackman's Clematis has now been very long in cultivation, has undergone various transformations, and is seen under several forms.

C. JACKMANI SPLENDIDA is the name I gave to the form with flowers in tufts or cymes. In

C. JACKMANI NIGRICANS, the ordinary form, which I have cultivated for fifteen or sixteen years, the flowers are violet-blue, almost black.

C. JACKMANI SUPERBA, a deep violet-purple colour, reminding one of C. Mme. Grangé.

C. JACKMANI VIOLACEA (Viticella modesta), a true Jackman's Clematis often seen with deep violet flowers changing to a bright violet colour.

C. MME. GRANGE, obtained by M. Théophile Grangé, of Orleans, is a handsome and favourite hybrid with fair-sized flowers in racemes and four to six spoon-shaped sepals more or less displayed. It is of a handsome purple-crimson velvet colour.

C. SPLENDIDA (Simon Louis).—A deep violet colour. (Viticella atro-rubens × lanuginosa.)

C. RUBRO-VIOLACEA (Jackman).—Maroon, changing to violet. (Viticella atro-rubens × lanuginosa.)

C. RUBELLA (Jackman).—Violet-purple.

C. PELLIERI.—A hybrid obtained by the late M. Alfred Pellier, of Mans, from C. Viticella × C. lanuginosa. The flowers, which are fairly large, are blue in colour, the centres a very bright blue. 1880.

C. RENAULTI GRANDIFLORA (Dauvesse).—In this the flowers are of a handsome deep violet-blue.

C. MME. FURTADO-HEINE (Christen).—One of the finest of the reds, and got from crossing C. Viticella rubra grandiflora with C. lanuginosa. It first flowered in 1883.

C. FRANCOIS MOREL (F. M. de Lyon).—Flowers formed of four sepals; in colour a handsome vinous red.

C. EDOUARD ANDRÉ (F. Morel).—Flowers formed of four sepals; in colour very rich velvety purple. A cross between C. Viticella and C. Francois Morel.

C. STAR OF INDIA (Cripps).—A fine deep violet, with black veins and purple centre. Flowers in corymbs.

C. GIPSY QUEEN (Cripps).—A deep violet velvet colour.

C. MME. BARON VAILLARD.—Obtain in 1885 by M. Baron Veillard, of Orleans, from seeds of C. Viticella azurea, Jackmani, and lanuginosa. The flowers, of fair size and fine rose-lilac colour, are very effective. It blooms from the end of August till the frosts come.

C. TURNERIGENSIS (Cripps).—This belongs to the Jackmani section. It is one of the finest blues and very striking. M. Lavallée describes it as a species intermediate between C. patens and C. hakonensis.

C. JACKMANI ALBA (Noble).—This handsome and vigorous hybrid and continuous bloomer is not a pure C. Jackmani. From its white and often semi-double flowers it belongs to the azureæ; by its inflorescence it belongs to the Jackmani. Its flowers, in foliaceous, drooping racemes, are charming when mixed with blue and purple Clematises.

C. MME. ANDRÉ (Baron Veillard).—One of the latest hybrids, and also one of the most deserving through its large, fine red-carmine-violet flowers.

It derives its red colour evidently from one of the *Viticella* crossed with the large-flowered *Clematis*.

C. MAGNIFICA (Jackman).—Of the same origin as *Mme. Ed. André*, which it preceded by a long while (about 1876), but not so red as *Mme. Ed. André*, being a violet-purple-crimson.

C. PROFUSA.—Flowers rose-purple, fairly large, and often semi-double, apparently a result of crossing a red *C. Viticella* with a *C. azurea*.

C. PERLE D'AZUR (François Morel).—A vigorous plant, abundant, and continuous in bloom from June to September. The flowers are large and formed of six sepals; the colour a pale azure-lilac rose.

C. ÉTOILE VIOLETTE (F. Morel).—(Graceful flowers, deep blue in colour, shaded and streaked with carmine.—*DR. JULES LE BELE*, in *Bulletin de la Société d'Horticulture de la Sarthe*.)

Erigeron speciosus.—This has never bloomed so well with me as this year, although I have had it in the same border for the last ten years. This may arise from being divided last autumn and planted in a fresh position in good soil. Evidently to get the best results from it you must induce a strong, firm growth. My method of growing this is in large masses. With me this year it has grown from 2 feet to 2½ feet high, and during June and July it was very effective.—*DOCKET*.

Myosotis dissitiflora.—This, the best of the Forget-me-nots, is rather a miffy subject in some gardens, and old plants often become a prey to a fungoid disease that unfits them for use as stock plants from which to propagate by division, and one has, perforce, to resort to seed sowing for renewing stock. This is the case with me on light and dry soil, and only in wet seasons can old plants be depended on to grow well and remain healthy through the summer. On the heavy soil at Coldham Hall the plant grows like a weed, and I lately noticed a large and healthy batch of nursery stock that will by-and-by be a pleasure to plant out. Inquiries elicited the fact that the plant gives no trouble at Coldham, and is always to be found in a healthy state.—*L. T. G.*

Violets and the hot weather.—In many gardens the long spell of dry weather has had a bad effect on these, more so where the soil is hot and dry. I fear in many gardens in the south and west its effect will be seen next spring. In a season like this those who grow Violets in full sun must give them much attention in damping, mulching, &c. For years I have given up growing them in the shade and have them this year in full sun. But for all this my plants are growing fast, are clean and look well, and up to the present time (August 20) I cannot see any spider on them. This year I was a little later than usual in planting them out of the boxes into the open ground. This was done early in June. After the planting was finished I lightly shaded the plants with some branches stuck in among them. As soon as the plants were established I gave them a good mulching of old spent Mushroom manure, and each night and morning they were well syringed with clear water. A day or two ago I gave them a good watering with weak manure water. I should advise not removing them into the frames too early, as when rain comes it will assist root action previous to being lifted.—*J. CROOK*.

Lilies and Galtonias.—In but few private places can Lilies of various types be seen in such profusion and vigour as they are now at Roughton Hall, near Bury St. Edmunds. The soil here, which also grows *Rhododendrons* to perfection, appears to suit the Lilies admirably, and they were there in thousands in great variety, and scarcely any disease was seen. The most plentiful appeared to be *L. lancifolium album* in great groups, with strong stems 5 feet high and carrying many flowers and buds on almost all stems. *L. auratum*, two and three years planted, was quite at home, the stems carrying in many cases from eight to ten flowers each. *L. longiflorum*, in established clumps also, was in fine bloom, the

plants being quite equal to many that are got from imported bulbs the first year after planting. The double form of *L. tigrinum* seemed to be a favourite Lily, and it was certainly very showy. At the time of my visit, perhaps the most striking effect to be seen was obtained by massing thousands of *Galtonia candicans*; rarely have I seen such spikes, and never quite in the same profusion. Being well set among plenty of greenery from shrubs, the effect was most happy. The portion of the pleasure grounds where these things were to be seen is being opened up, to obtain better views and to make room for more extensive planting of hardy flowers in large masses, which seem to be appreciated at Roughton, and which can be made so effective when well done.—*L. T. G.*

Lobelia Carmine Gem.—This lovely perennial kind may safely be placed in the front rank, a position to which it is entitled as much for the new and novel as well as striking shade of colour as for its great freedom of flowering. When shown a year or so ago at the Drill Hall it was admired by a large number because of the novel shade of colour—a shade, by the way, all too inadequately expressed even in the above name, but even then no idea could be obtained of its great freedom of flowering when planted out in good ground. In this latter way we have recently seen it in grand form in some large beds at Gunnersbury House, where Mr. Hudson has made a feature of the plant. There are two beds of it in these gardens, separated from each other by a third and larger mixed bed arranged with fine-foliaged things, *Cannas* and the like. The ample varying greenery of this central bed is by no means lost by the brilliant effect of the *Lobelia* at each end. The plants, too, are wonderfully profuse in flowering, as the large central spike is just fading, and the endless side spikes are just now surpassingly rich and brilliant in tone. This is the more gratifying in a season like the present, unequalled perhaps for its combined heat and drought; therefore the plant may be confidently recommended for effective grouping generally. The lesson here gathered in a garden and situation far from favoured is a good and useful one, as no one who plants in fairly good soil need fear the results. It is the finest hardy flowering plant we have seen for many years, and those who garden for effect should use it freely and, of course, judiciously. The tallest spike is about 3 feet high, the endless lateral spikes about 2 feet or rather more.

BICOLOR DAFFODILS.

It is within the limits of the "bicolor" race of Daffodils that we find the most worthy, as indeed the most valuable, of the great family of *Narcissus*. This is so, whether it be from the point of view of individual beauty, for cutting or for general effectiveness in the garden, wherein, happily, they are among the most easily managed of their tribe. Some of them indeed, as, for example, the well-known *Horsfieldi*, or *Empress*—splendid representatives of the section now under notice—are so generally good in so many gardens, and, of course, varying classes of soils also, as to merit the distinction of being among the most vigorous and reproductive of all Daffodils. And to say this of two such sterling kinds is but doing them, as it were, simple justice, for it would be difficult indeed to name another pair so easily and cheaply procured of which so much may be said without fear of contradiction. Indeed, they are by their very robustness and vigour just the kinds that may be recommended to any amateur who must, perforce, leave many of his bulbous plants in the earth year by year, and by so doing have not the least fear but what they will duly appear in spring finer and better than ever before. And what is true of those mentioned as a pair is equally true of others as

individuals, and of these none in greater degree than that so well shown in the accompanying illustration, *N. b. Grandee*, so long known by the name of *N. b. grandis*, the latter giving place to the former at one of the conferences on these flowers a few years since, when it was unanimously decided that no Latin name should be applied to varieties of plants of garden origin, and as "a Rose by any other name would be as sweet," so also this handsome bicolor retains all its valuable characteristics still. Individually it possesses a vigour even greater than *Horsfieldi*, while as a really reliable sort in many soils it can hold its own with many—if not, indeed, most kinds. Its chief value to the gardener is its lateness in flowering; indeed, save for the smaller *N. bicolor* of *Haworth*, *N. b. Grandee* (see page 239) may lay claim to being the best of all the late bicolors. In truth, even this slight qualification may be swept away when, as now, we are regarding these things from a garden standpoint, for the bicolor mentioned will never equal the nobler *Grandee* for general effect. Much of the fine character of the latter is well shown in the picture, but the clearness of the colour, both in the segments and in the trumpet, can only have full realisation in living specimens. The broadly imbricated perianth segments are a good point in the variety *Grandee*, and perhaps very few of these kinds give a better effect in a vase than a good handful of its flowers. But while I regard it as a very fine *Daffodil* for general effect in a garden, I am not slow to recognise its shortcomings, or fail to see how or where it may be improved. It may be improved considerably in various ways, chiefly, however, by length of stem and much refined perianth segments.

These latter are, indeed, rough when we compare flowers with those of the chaste and beautiful *Mrs. Walter Ware*, a finely-finished flower indeed, and one that speaks for itself among a handful of good things. *Mrs. Walter Ware* is a bicolor which will live for ages, provided its constitution is as good as others named. Great size it does not possess, but there is incomparable beauty in its form and in the well-defined colours, while the horizontal crown is beautifully reflexed at the brim and nicely proportioned throughout. It is a free-flowering kind, and a hundred of its flowers are really satisfying and pleasure-giving to a degree. The bicolor *Ada Brooke* is a useful kind also, chiefly for filling in the gap between the early and late kinds, while for colour and form it is also excellent. In the trumpet of this kind there is richness of colouring not always found in this race. Among the most chaste, however, the lovely *J. B. M. Camm* will ever hold front rank. It is indeed a flower possessing the highest refinement and withal well proportioned and of good substance. The exquisite beauty of this kind may be extolled to almost any limit without saying one word too much in its favour. It is indeed the fairest of all the bicolor race. Other good and worthy things are *Portia* and *Cambaceres*, both of good form and substance. Still in the same group we find such as *Mme. Plomp*, in which the large segments of the perianth are very broad and white and the trumpet rich in colour; happily it is possessed of a fine vigorous habit. Another excellent kind is the new *Victoria* that fitly made its debut a year ago. This in every respect is an excellent bicolor *Daffodil*, one that is full of promise for the future. The growth is not only sturdy, but the trumpet, which has a nearly horizontal aspect, is very imposing. Still to be mentioned is that magnificent kind *Weardale Perfection*, a princely bicolor indeed. This kind has no equal in its stately bearing,

its monster flowers or massive growth. How near it the lovely Ellen Willmott will be when these can be seen side by side in growth time will prove. As a flower, however, Ellen Willmott is a superb, highly-finished kind, a flower, too, that renders further progress difficult. At the same time, with two such noble Daffodils as the last-named, who can guess what the future of this race may be? E. J.

FLOWER GARDEN NOTES.

PLANTING BULBS.—Among the different items of flower garden work to be carried out in September, not the least important is the planting of various bulbs that may be relied on to give a supply of flowers for cutting. I am not writing of naturalisation, nor has the suggestion much to do with the flower garden, as things planted solely to produce cut flowers are hardly likely to be serviceable in the way of a display, and if they can find a place in odd nooks and corners, so much the better. Where bush Gooseberries and Currants are set somewhat widely apart and kept within bounds, the central space, say about 1 foot or 18 inches in width, answers admirably for such things as Snowdrops, Chionodoxa, Spanish Iris, and Daffodils. The width required should be forked deeply and broken thoroughly—not broken merely on the surface, but right through the depth: large, hard lumps about where the bulbs will rest are not conducive to an even or good growth. Daffodils are easily first among bulbous plants for the purpose. They are in general favour, and a judicious selection will furnish flowers for three months. I would suggest, with due regard alike to a long-sustained display and economy in the purchase of bulbs, Obvallaris, Princeps, Rugilobus, Horsfieldi, Barri conspicuus, Johnstoni Queen of Spain, and the single and double Poeticus. The fifth and sixth on the list are a little more expensive, but I regard them as indispensable in any collection of Daffodils. As for the newer varieties, they are at present beyond the means of the ordinary grower, and it will be some years before, for general purposes, they are likely to supersede the sorts named above. The strengthening of bulbs and yearly increasing flowering of different varieties are possible questions of soil and situation. With me the best in this respect is the May-flowering single Poeticus. I am not prepared at present to go into statistics, but can say that from bulbs planted six years ago at 12 inches each way, twelve, fourteen, and in some cases sixteen flowers were obtained this year. The wealth of bloom secured from even a limited area is therefore very great: in fact, from this standpoint I should put the May-flowering Poeticus easily first among all the kinds I have had to do with. In the case both of Daffodils and Spanish Irises it will be found advisable if circumstances permit to plant in different situations that the season may be prolonged. On a north-west border I find them quite a fortnight later than where they are fully exposed, and as a matter of course in the semi-shade the flowers when fully expanded are longer retained. This prolongation of the season by planting in different situations is worth the attention of all who have to provide a lot of cut flowers. I have already tried it on a small scale, and, finding the experiment in every way satisfactory, have just done a narrow north-west border thoroughly well with the view of planting thereon a portion of a good batch of hardy flowers raised from seed that are now quite ready to be transferred to permanent quarters. In such a position I am still cutting (September 9) in good condition Gypsophila, Montbretias and Pentstemons in variety, also in annuals two varieties of Coreopsis and Godetia, Salpiglossis and plenty of Mignonette.

TUFTED PANSIES were very fine in spring and early summer, but did not last out. On our light, dry soil the prolonged drought was too much for them, and despite two or three good soakings they began to fail towards the middle of July, and

gradually grew worse until the plants were brown and withered. This is right in the open; in partial shade they are still fairly good. Finding there was no chance of pulling them round, I had the plants up towards the end of August, divided them as much as possible, dipped them in a thick puddle of soil and water and replanted, giving the beds a thorough dressing of half dry cow manure as they were dug up. This mode of increasing the stock was absolutely necessary this year, as cuttings on most varieties were not obtainable. When nice stuff can be secured I should, however, always propagate in the latter way. The argument is sometimes advanced, why trouble about this mode when you can split up the old plants either in autumn or early spring? I answer that with me plants from cuttings come earlier into flower, individual blooms are finer and the flowering season is more sustained; also, it must be remembered, that many varieties grown and known as Tufted Pansies have little or nothing of this particular habit, and growers who depend on this to secure a stock for another year are likely to be grievously disappointed. I have before suggested the elimination of many non-tufted varieties or those which only show this characteristic in the slightest form, and to simply class them as bedding Pansies possibly in some future lists we may hope to see this done. A straggling habit cannot be said to be totally foreign to the true tufted forms. All Pansies will run given certain conditions. A plant or two of *Violetta* for instance came up among a clump of Iris in a cool, shady position, and, strengthened doubtless by the heavy winter mulching placed on the Iris, they ran all over it by the end of the season, some of the shoots being over 2 feet in length.

THE CONTINUED DROUGHT.—It is difficult to estimate the after effects of this on what may be termed some of the permanent inmates of the flower garden, such as American plants, hardy Azaleas, and the majority of choice deciduous and evergreen shrubs. I use the word choice not as meaning anything particularly rare, but as applied to those plants which in their respective seasons help so much to beautify different parts of the garden. We are suffering considerably, especially on slopes that are more or less exposed to the sun. My own impression is that where plants are not actually killed, next season's bloom will be weak and poor and growth of the most meagre description, for the premature loss of leaf is not so much due to the direct influence of powerful sun on the same as to the drying up of many of the fibrous roots and consequent weakening of the constitution of the plant. On all light soils the value of a heavy winter mulching cannot in a season like the present be over-estimated. Almost anything to a certain degree will answer the purpose, that is if manure is not obtainable. Rough leaf soil or the dead foliage of such trees as *Taxodium distichum* will be found highly beneficial in preventing the drying out that comes with such a long-continued drought. Planting on soil above mentioned will be found in the autumn of '98 somewhat risky. Where it must be done I should strongly advise working round each plant a liberal dose of a compost consisting of two-thirds stiff road sidings and one of cow manure. E. BURRELL.

Clavonid.

Omphalodes Luciliae.—It is usual that the foliage of this very rare and beautiful rock plant is of a glaucous or silvery grey tone on both surfaces, as also the petioles, but in raising seedlings of the plant it sometimes happens that this characteristic marking of the leaves is quite wanting, the leaves assuming a pale pea-green instead, and therefore losing somewhat of their natural charm. There is no apparent variation of the exquisitely beautiful flowers, which is a curious and interesting fact, seeing it is in these latter in most flowering plants, and such as are raised from seeds especially, that the variation usually takes place. But even the green-leaved form is worth growing should it appear, and both

are equally free and profuse in flowering. Where good plants exist, the earliest flowers should be near maturing seeds. These, to make sure, need looking over daily. A good way to make the seed secure is to put a hand-light over the plant, and if from any reason the plants cannot be looked over, put in an inch of sandy soil and allow the seeds to fall and germinate in the light. Growth, which is slow, does not usually take place until spring. At all times slugs are very fond of it.

GARDEN FLORA.

PLATE 1189.

THE SPECIES OF CAMELLIA.

(WITH A COLOURED PLATE OF *C. BONCKELAARI* AND *C. SASANQUA* VARS.)*

Now that the genus *Camellia* includes *Thea* (the Tea plant and its allies), it comprises about fifteen species in all. These are found mostly in India, China, and Japan, but the genus is also represented as far to the south of Asia as the Malayan Archipelago. In gardens it is almost exclusively represented by *C. japonica*, a species whose numerous forms fill an impor-

Camellia tree in the open air.

tant place in greenhouses and conservatories even at the present day when their popularity has greatly declined. The present plate, it is hoped, may direct the attention of horticulturists to the value of the *Camellia* as a hardy shrub. Hitherto, except in the extreme south and south-west, it has been almost entirely grown under glass, yet it has been proved that even near London, when given suitable positions, many of the varieties of the common *Camellia* are most valuable and striking hardy evergreens. The variety illustrated in the accompanying plate is an old and well-known one. Its flowers are amongst the brightest in colour and the prettiest and most informal in shape of all the garden varieties. The picture is of interest because the sprays were taken from a plant which has grown without the slightest protection in the *Rhododendron* dell at Kew for many years. About a dozen other varieties are also grown there. In places sheltered from north and east winds there need be no fear of their suffering from cold. We are not likely to experience a more trying time for

* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Godart.

evergreen shrubs than the early part of 1895, yet this variety *Donekelaari* and the others were not in the least affected then. Their lateness in starting to grow frees them from all danger of late frosts. The foliage of the *Camellias* is of itself a striking feature out of doors in this country, for we have no evergreen with foliage possessing quite the same lustrous black-green hue. The *Camellias* have the same dislike to very chalky soil as the *Heaths*, but with this absent they will thrive either in loam or peat. They appear to succeed best where there is a slight shade up to midday, but, on the other hand, fine specimens have been grown in positions fully exposed to the sun. I think the red semi-double varieties like that now figured are the best for out of doors. Brilliant red flowers of the same shade as this are very rare among hardy shrubs at any season and are particularly welcome in March and April. At the same time I would advise anyone who has spare *Camellias* of any sort or colour, even if not in the best of health, to give them a trial in the open air. They are of

There is a very interesting book, probably rare now, published in London in 1831, which deals with the species and varieties of *Camellia* then known. A beautiful coloured plate is given of each one described. The authors are Alfred Chandler and W. B. Booth.

C. RETICULATA. As a greenhouse plant there is no question but that this is the finest of all *Camellias*, yet, curiously enough, it is one of the rarest—rarer even than *C. Sasanqua*. Both at Kew and at Chiswick it has been grown with great success. The original plant was introduced to the gardens at the latter place by a ship's captain in the service of the East India Company in 1820. It was growing there till within a few years ago, but has been removed. Perhaps the finest plant in the country now is a specimen in the temperate house at Kew about 18 feet high. This is covered with healthy foliage and flowers freely and regularly. From all the forms of *C. japonica* (with their invariably lustrous leaves) it can be easily distinguished by the dull green colour of its foliage. Its flowers are the largest in the genus; they average 6 inches in diameter and are

tinues into the new year. The flowers are from 1½ inches to 2 inches across, and in the true wild specimens are said to be always white, but the cultivated varieties have pale pink to deep rose flowers, and we have them also both single and double. The Japanese name for this *Camellia* is "*Sasan-kuwa*," a modification of which has been adopted as the specific name. The leaves are small, about 2 inches long and 1 inch broad, with rounded teeth at the margin, and of a deep glossy green, which is in one form variegated with a creamy white. The species was first introduced in 1811.

C. ERYTHROIDES is a very curious species, probably not now in cultivation. It used to be employed by the Chinese as a stock on which to graft other species, and it was in this way it was originally introduced to Chiswick. Some grafted plants were imported in 1822 the grafts of which died, whilst the stock sprouted and grew, and, ultimately flowering, proved to be a new species. The present name was then given by Dr. Lindley. It is the smallest in leaf and flower of all the *Camellias*. The leaf is three-quarters of an inch to 1½ inches long, and the flower (which is white) half an inch across and cup-shaped. This species has latterly been found growing wild on the mountains of Formosa—a shrub 8 feet high—also in the Hupeh province of China.

C. ROSEIFLORA.—The history of this species is not known so far as regards its introduction to cultivation. It has been found in China and in Japan, although it is doubtful whether it is really a native of the latter country. It is a dwarf shrub resembling *C. Sasanqua*, but more lax and straggling in habit. It has small ovate-acuminate leaves of a dark glossy green and serrated. It flowers in December, the blossoms being single, 1½ inches across, and of a clear rose colour. It flowers every winter in the temperate house at Kew.

C. HONGKONGENSIS is cultivated at Kew, but has not yet flowered. It is a tree, and was discovered in Hong Kong about 1849 by Lieut.-Col. Eyre. In 1859 it was said that only three trees of the species were known in the island. It has a large leaf somewhat like that of a Cherry Laurel and rosy red flowers 3 inches across.

C. THEA (the Tea plant).—This is of little value as an ornamental plant, and is usually grown merely because of the interest attaching to a shrub so important to civilized nations. It is an evergreen, requiring the temperature of a cool greenhouse, and has oblong, very dark green leaves and small white flowers. The real native country of the Tea plant appears to be Northern India. It is doubtful if it be really indigenous to China. W. J. E.

Spray of the single white *Camellia*. From a drawing by Agnes Cook.

course moisture-loving plants, and the necessity of keeping them always damp at the root involves some care in watering plants that have just been turned out of pots in which they may have been growing for many years.

Camellia japonica is a native of Japan and is a common plant in the southern parts of the empire, where it becomes a tree 30 feet to 40 feet high. It first became known in Europe at the beginning of the eighteenth century, and a figure of it was published as early as 1702. Considering the great attention it has had in Europe and how much it has been improved under the cultivator's hands, it is curious to learn that it is less frequently to be seen in Japan than *C. Sasanqua*, and that it is valued more for the oil pressed from its seeds than for its flowers. This oil is used by Japanese women for dressing their hair. Professor Sargent observes also that in a wild state the flowers of the *Camellia* are red and do not open fully, the corolla remaining cup-shaped till it falls ("Forest Flora of Japan").

very frequently over 7 inches. They are semi-double, the central cluster of yellow stamens being surrounded by two or three rows of petals beautifully wavy and of a rich soft rose. I am not aware that this *Camellia* has been successfully grown out of doors in this country; in the warmer parts it would almost certainly thrive in the open, especially against a wall. In any case the coolest greenhouse suffices for it, and to those requiring fine shrubs for the conservatory nothing better can be recommended than this. Its flowers are entirely free from the stiffness and formality which have to so great an extent brought about the decrease in popularity of many forms of *C. japonica*. It is a native of China.

C. SASANQUA.—Compared with either *C. japonica* or *C. reticulata*, this *Camellia* is neither so showy nor so vigorous a grower. When seen at its best, however, it is a charming shrub. It is a native of China and Japan, and in the latter country appears to be more cultivated than *C. japonica*. Professor Sargent says that in the southern parts of the country it is very frequently met with as a small bushy tree. Both in Japan and in Europe it commences to flower in November, and con-

The "formal" garden.—In the discussion of all art now-a-days new and often needless words are used, often to make obscurity more obscure, and in any case giving more room to the numerous writers on artistic subjects, whose words are far more copious than their ideas. Of late the garden has been subjected to this, and now-a-days, if people have only a straight walk and a few level beds near it, it is called a "formal garden." The word is quite redundant, as, ever since gardens were made, judging by all the evidence we have, whether of Egyptian or Assyrian, or of Roman and Greek gardens, or tapestry and old pictures, necessarily all gardens about a human dwelling followed simple lines, and were, as regards plan, formal. In a recent issue of *The Studio* we noticed the words "Formal Gardens" in Scotland, and on examining the article to find out what it was about, we found a number of plans, sections of the courtyards and absolutely necessary roads, courts, and dividing lines about country houses. —*Fibb.*

Pteris tricolor. Some capital examples of this Fern were to be seen at the Drill Hall last week, and if not large, were both well coloured and carrying several good fronds each. Though an old plant in cultivation, it is by no means an easy one to grow successfully, but is occasionally met with in good condition in the least expected

places. The plants referred to recall an instance in point where in an old lean-to greenhouse, in a much mixed assembly of odd plants, I found some years ago the finest examples I have seen. Nor was it any special culture that was responsible for the success in this case, as the gardener candidly informed me the plants shared the treatment given to all else in the house, and, what is more, the grower did not even know the plant he was growing. The house was only heated when frost was imminent, and at other times kept as cool as possible. This and the fact that the house was much shaded constituted the only items I could see that would in any degree account for the handsome, well-coloured, and perfect fronds produced by these plants.

THE WEEK'S WORK.

KITCHEN GARDEN.

ROUTINE WORK.—The prolonged drought is very trying to the vegetable crops that need ample supplies of moisture to make their growth before the winter season. Most of the Brassicas require copious supplies of moisture, and it often happens that watering is done under great difficulties, the supply in many places being none too plentiful. I find the best way is to give a thorough soaking, going over the crops several times in one day. The water then finds its way to the roots, and if a mulch of any kind can be given it will be of great benefit to the crop. Mulching is not always practicable, but it well repays in the end, and unless assistance is given to such crops as salads, early autumn Cauliflowers, and similar crops, the results will be poor. Many shifts may be made in giving a mulch, as even long straw litter placed over the surface will conserve the moisture. Late planted Broccoli, Kale, and Savoys will need more moisture than those which have been planted longer. These are most valuable after Christmas, and it will be well to keep them growing till we get rain to assist them. The earth being so warm, with a genial rainfall later on the growth will be rapid, and lost time will be made up if the autumn is favourable. The planting of the earliest spring Cabbage will, I fear, be delayed by drought. It is not advisable to plant unless moisture can be given regularly. On the other hand, much may be done by preparing the quarters and drawing drills. Seed beds should be given ample moisture, and in case there was thick sowing, it will be well to draw some of the largest plants to give others room and prevent them getting leggy. Lettuce seeds for early spring supplies will have germinated badly if not well supplied with moisture, and it will be well to make other sowings at once if the plants are at all short, as seed sown now will make fair plants for the spring planting. Late Peas in light soils are doing badly owing to the heat. It is a difficult matter to keep them growing and free of mildew, and it has been necessary to give repeated dressings of the mixture advised a few weeks ago. Mulching must not be overlooked even with the best soil and position, as the haulm is so liable to insect attacks. A thorough watering twice a week will be needed to keep the plants healthy.

RUNNER AND DWARF BEANS.—The Runner Beans will cease to produce freely unless given liberal supplies of water, as the flowers drop so badly. Much may be done to assist setting by pinching the tops and not allowing the plants to go above the tops of the sticks. The plants will also well repay liberal supplies of liquid manure. These given weekly will build up strong bottom growths, and from these will be obtained a later supply. The climbing French Beans will need more stopping than usual owing to the heat and drought. There is a tendency to gross top-growth and a naked base, and it is well to pinch the points to promote freer setting at the lower portion of the haulm. Few vegetables give a better return than this new type of Bean, and,

kept well fed, they will give a wonderful supply. The weather has been bad for dwarf Beans. Owing to the heat the plants in light soil have been attacked by red spider. To prevent this, nightly dews overhead to maintain a healthy growth have been necessary. Plants sown for a late supply should be given ample moisture late in the day, and, if possible, a mulch of spent manure will be beneficial. I water overhead every evening.

SPINACH.—The seedlings raised early in August will need thinning if sown at all thickly, as with cooler nights and more moisture, growth for the next few weeks will be vigorous. It is not well to disturb the plants in dry weather unless the rows are watered previously, as it loosens them and they suffer badly. Should any pest attack the plants it is well to give dressings of soot, and if liquid manure can be spared, this will promote a large leaf-growth. In some places owing to drought the early autumn sowing is none too good. It is not too late now if the soil is moistened to assist germination. Sown thinly, the plants will be useful next April, at a season there are none too many green vegetables. It is well to sow a large kind. Carter's Long Standing is an excellent variety for the winter and spring supply, this giving large, succulent leafage and being very hardy. To save time at this late season I have found it advantageous to soak the seed before sowing for a few hours, and if sown in rather deeper drills than usual, not making level on the surface after sowing, it is an easy matter to give moisture during the early stages of growth.

ASPARAGUS.—With so little rainfall I fear Asparagus in raised beds and light soil will have suffered. Where Asparagus has had food given in the way of liquid manure, the growths are much better and still active. In any case few plants will better repay for food given, and in places where irrigation is possible there is no better means of culture. Beds that are forced should not suffer from want of moisture, and, failing liquid manure, it is not too late to give such aids as soot, salt, or other quick-acting fertilisers. It is better to give the latter in small quantities, well watering them in. Newly-sown or planted beds have had a bad season to contend with and growth will be later. The surface should be kept hoed over after giving moisture, and in case the seedlings are too thick, it is not too late to thin out, as this will give the plants a better chance in the early spring.

SEAKALE.—In light soils the plants have not made so strong growth as usual, and often after a spell of hot, dry weather we get a rainy period, which causes the plants to make a late growth. The latter is not desirable with plants needed for forcing. The old leafage may now be removed; I mean such as shows any signs of decay, as this will give more light and promote early ripening. All weed growth should be destroyed, but there will be few weeds if salt has been used freely. Plants not needed for lifting early, or those forced in their growing quarters, may still be given food, and any side or weak growths will need to be removed, as if left, the produce when forced is of no value, being too weak. To prevent the earliest plants making a late growth, I have cut down the sides with a spade. This does not harm the main shoot and the leafage ripens up. Of course such treatment is only necessary with a few plants needed to force at the end of next month, and does not apply to later supplies or young plants that are being grown for a late spring supply.

CELERY.—The heat and drought have not been favourable to the growth of Celery, but where moisture has been given freely the produce is fair. Moulding up should be done piecemeal. Previous to the earthing up it will be advisable to give a thorough watering, as if the latter is overlooked the plants will not winter well and become tough and run badly. Previous to giving fresh soil it will be advisable to give a dressing of soot. This is an excellent fertiliser; at the same time it keeps off slugs, and salt also adds to flavour if given in small quantities previous to watering.

Many give the final earthing up before the growth is sufficiently advanced. This causes decay in the centre of the plant, and should be avoided. I leave my plants as long as possible before earthing, only placing small quantities at one time to keep the plants erect.

TURNSIPS.—The seeds sown a month ago have not made the progress one would desire owing to the drought, and it will be well to hoe frequently between the rows, as this in dry weather prevents the earth from cracking. Watering in many gardens will have been necessary in exposed positions. It will be well to water overhead at night. This will check the fly, and if dry wood ashes mixed with a little flowers of sulphur can be given when the plants are damp, the fly will not attack them, and all danger will be past when we get more moisture and cooler weather. In case the seed has failed to germinate, it will be well to make another sowing. Although full late, Turnips grow so rapidly, that they will soon bulb and be quite large enough for winter supplies. Such kinds as Red Globe or Model are excellent for late sowing. I noted the value of the yellow-fleshed varieties a few weeks ago. It is a good plan to cover the drills after sowing to assist germination, and to thin as early as possible to encourage rapid growth. S. M.

FRUIT HOUSES.

POTTING ORCHARD HOUSE TREES, &c.—One of the most important operations at the present time is the potting of these, preparation for which should be made without delay. I always like to have the early trees, that is those which are depended upon for first early forcing, potted during the latter end of the present month, proceeding afterwards with the work as continuously and persistently as possible until the whole collection is done. In every case, however, make an effort to get those for forcing attended to at once. Prepare a fresh batch of pots so as to have sufficient for a portion of the trees rather than be under the necessity of using the same pots again on the same day before they have had a chance of aeration or sweetening; wash these, and as cleanly as possible. The first to be used will no doubt have been washed, whilst any new ones hitherto not in use will need a thorough soaking previously. See that the crocks (or broken chinkers if potsherds be scarce) are clean also. Drain the pots liberally, and upon the drainage let a handful or so of rough Vine border compound be sprinkled, such as half-inch boiled bones, horn shavings, &c. (Bentley's coarse answers the purpose well). Avoid the use of cracked pots if not carefully wired; even then they are apt to deceive all but experts in watering. The soil best suited to pot fruits in general is what is known as Bantstead loam (in the south), with the addition of the top spit of an old pasture that is not so retentive or adhesive as the former, which, however, may predominate to a small extent. Take care not to break up the loam too much, some of the coarser portions being easily disposed of upon the drainage. To the loam add about one barrowful of old mortar or lime rubble to a cartload of soil, this being broken down to about the size of common nuts. About one-fourth, or at the most one-third, of bone-meal should also be added, or in its place a smaller portion of artificial manure in which there is a good percentage of phosphates. Some well-decomposed manure that will crumble up finely should also be added, such as that from the farmyard, failing which, that used for Mushroom beds will answer the purpose. Neither road grit nor sand is needed unless all of the loam has a tendency to be heavy. Mix together well and be prepared to protect the heap should heavy rains threaten. A slight damping after the long period of drought will be beneficial rather than otherwise. The question is often asked, "Do we pot the trees every year, and if so, are the roots reduced?" The answer is, "Yes" to both queries. The trees should be potted afresh every season, even those that may not have borne good crops of fruit. Do

not be led away with the idea that it will be better not to pot these: as a general rule it is best to pot every tree, but in doing this do not commit the far too frequent error of over-potting, this being the crux of the whole question with many growers. To pot into larger pots without reducing the old ball at all is not to be thought of. The strong succulent roots need reducing, and so do the fibrous ones, otherwise some of these latter must decay in due course. When a tree is seen to be making sufficient growth with a proportionate amount of sound fruiting wood, so that the pot does look small to its size, then a larger pot may be chosen, but only one size larger even then. For the next two years at least that tree will not stand in need of a larger pot. It is a fatal mistake not to repot trees that have borne good crops, for these will have practically exhausted the soil within their reach. Reduce the balls in every case, and that sufficiently to secure room for conveniently ramming the new soil firmly, this, too, being an important matter. Never attempt to hurry through the potting; if this be done it cannot be performed as it should be. Leave sufficient room for watering, also bear in mind the top-dressing during growth next season. After potting stand the trees in as open a spot as possible, so long as they do not stand in danger of being blown over. Water once directly afterwards and syringe daily for a time if it be not showery. Guard of course against standing the trees upon the soil so as to endanger them against the incursion of worms, as these may afterwards cause a deal of trouble. Special care should be taken with Cherries in pots not to overpot them in the slightest degree. At the same time the loam for these may be slightly less manured, but in other respects the same. Do not in any case hesitate to re-pot because the leaves have not fallen. So long as the growth has ceased and the wood is well ripened there need be no delay. It is much better to re-pot early in order that the roots may again be on the move as soon as possible. Trees now in bearing in the latest houses need to be watered carefully, taking care not to overdo them when the fruit is ripe. Those which are relieved of their crops should at once be placed outside in a sunny position, but do not re-pot these yet. Leave them rather for at least another month, by which time the foliage will be well hardened, and any sappy tendency in the wood reduced too. Add to the stock as the requirements may arise: a few fresh additions every year will allow of a year's rest to those trees which have borne heavy crops for years in succession. Do not think of potting up trees from open quarters with the view of forcing them. One might as well attempt to run in a race without any previous training for that specific purpose. Even for late fruiting it should not be expected to see any such results the first season afterwards, preparation being essential to success.

LATE FIGS NOW FRUITING.—As I am writing these lines, one cannot but contrast the changeable character of the weather. During the day-time the thermometer stood at 87° in the shade, and within forty-eight hours therefrom the grass in the open was white with frost. If any Figs are, therefore, now left upon outside trees which promise to ripen, let them be protected at night at least by means of canvas, but, better still, by glass as well. Figs planted out in houses and now finishing up their latest fruits (or second crop) will need warmth to fully develop their good qualities. At least 60° at night should be maintained, 5° more being better if the latest fruits be still in the green stage. Guard also against any excess of moisture, otherwise cracking or splitting will ensue: this may not altogether matter if only slightly apparent, but it often happens to be more than is desirable, causing decay ere the fruits are matured. Both Negro Largo and Nebian are liable to this failing as well in pots as in open borders, but more so in the latter case. Late Figs in pots which were retarded as long as possible in the spring are now yielding good returns, promising to do so for a

long time yet. That this is the better plan for late crops of Figs is beyond any doubt, being evident to anyone who has had any experience at all. The varieties just named are about the best and most promising now, the latter being nearly a month later than the former, which is now ripening its first fruits. At the time of writing both Figue d'Or and Bourjassotte Grise are in excellent condition, too. Figs in pots for late fruiting should have the benefit of light and well-ventilated houses, but such as can be sufficiently warmed for the purpose to a minimum temperature of 65° by night, otherwise the condensation of moisture will act injuriously during the damper and possibly foggy weather of the next month and onwards. Be extremely careful now in the watering, taking care both not to water in excess to the slightest degree as well as to avoid drought, the safer and better plan being not to allow this work to change hands at all. Young stock from eyes or cuttings this spring will not infrequently show a few fruits, this season having been favourable to this tendency. If this be the case, it will be advisable to ripen the fruits even at the expense of keeping them in warmth longer than would otherwise be attempted. Any increase in the stock of pot Figs from outside should be made without delay, selecting them to suit the circumstances, whether dwarf or otherwise.

HORTS.

FRUIT AND VEGETABLE CROPS.

NORTHERN.

Crofton Hall, Wakefield.—In this garden there is a fair crop of Apples: in the surrounding district the crop is light. Pears are quite a failure. Plums are also a light crop; Strawberries and Raspberries very good. Bush fruits are very good; Black Currants excellent.

Vegetable crops are doing well.—CHARLES WATTS.

Lowther Castle, Penrith.—Apples are under average; Pears the same; Plums under; Cherries average; Apricots under; small fruits over, very good, and Strawberries over, very good. Royal Sovereign and Countess are two excellent varieties. Of the former I gathered five fruits which weighed half a pound.

The season has suited the vegetable crops, which are all good.—F. CLARKE.

Edenhall, Langwathby, R.S.O.—The fruit and vegetable crops in this neighbourhood are all that could be desired. We were troubled with occasional late frosts, but no serious damage was done. Apples and Pears are a good average crop. Plums are very thin, while Apricots and Cherries are good. Morello Cherries are very heavy and the fruits very fine. Strawberries have been a heavy crop of nice fruits. Raspberries are good, and all bush fruits are a heavy crop of nice clean fruits.—ARTHUR C. SMITH.

Ripley Castle, Yorks.—The show of blossom on all fruit trees in the past spring was phenomenal. The resulting crops are, I am sorry to say, not in proportion to the promise. This I attribute to the cold weather during the latter part of April and through May, which caused the young fruits, especially Plums and Cherries, to fall in great numbers. Apples are erratic, some varieties carrying a full crop, others none at all. Amongst those bearing most abundantly may be mentioned Warner's King, Ecklinville Seedling, Lord Suffield, Grenadier, Mère de Ménage and King of Pippins. The fruit is free from blemish and gives promise of developing to good average size. Pears are under an average as regards crop, but the quality gives promise of being good. Those bearing most freely are Jargonelle, Marie Louise, Citron des Carmes, Louise Bonne of Jersey, Glou Morceau, Moorfowl's Egg and Althorpe Crassane. Plums are a very thin crop and the trees have been terribly infested by blight; Cherries a poor crop all through. Apricots are good, ripening rather later than usual.

Gooseberries, Red and Black Currants and Raspberries are heavy crops; Strawberries a heavy crop, but fruits small owing to drought.

It has been a very trying season for vegetable crops, owing to the drought, which in this district made itself more manifest upon crops in the garden than during either of the preceding dry seasons. Peas have cropped well, but the season of each sowing has been a short one. Late varieties after the recent heavy rains will, I hope, be more continuous in their cropping. The Brassica tribe has given a great deal of trouble; grub has been prevalent, and never before have I been troubled with so many going blind. Carrots are the worst crop I ever had. Potatoes are good, crop heavy and quality excellent. Onions are splendid and do not seem to have felt the drought. All other vegetables are good.—J. TENNINGTON.

MIDLAND.

Gopsall Gardens, Leicester.—The weather here during the time when the fruit trees were in bloom was anything but favourable for a good set of fruit, rough winds and heavy rains prevailing. The effect of these was very apparent, especially on the Apples, Pears, and Plums, which crops are below the average. There are but few fruits in this district. Of Apples, Lord Suffield, Manks Codlin, Cellini, and Northern Greening are the best; and of Pears, Easter Beurré, Beurré Diel, Beurré d'Aremberg, Glou Morceau, and Louise Bonne of Jersey. Of Plums, Victoria is good; all other varieties quite a failure and the trees affected with insects, necessitating a great deal of labour in getting them clean. Apricots have done well. They were well protected during the blooming and setting period, and we are well repaid with a grand lot of fruit above the average in quantity and quality. Peaches also are good. Strawberries are up to the average, Royal Sovereign coming out well, also Sir Joseph Paxton and Anguste Boisselot, especially on the two-year-old plants. Morello Cherries are good, although this has been a troublesome season with the black aphid. Dessert Cherries are not grown outside, but under glass have been very good; Gooseberries, Red and Black Currants a full crop, and quality well up to the average.—J. LEE.

Thoresby Hall, Notts.—Fruit promised to be abundant and set well, but owing to the cold cutting winds and little sun after setting they did not make a move, but dropped off. Of Apples we will have a fair average crop. All small fruits are plentiful and of good quality. If the weather continues so cold I am afraid Apples and Pears will be poor, both as regards size and quality.

The vegetable crops in this district were not nearly so early as usual. On June 15 we had a sharp frost, which killed Potatoes and dwarf Beans, and gave a severe check to all tender things; what with the east winds and little sun all early vegetables were considerably later than usual.—A. HENDERSON.

Alton Towers, Cheshire.—The fruit crop around this district cannot be considered very satisfactory. Apples are poor and below the average, and the trees have been much blighted. Pears are very thin. Stone fruits are a complete failure, with the exception of Cherries, which are fairly good. Small fruits are plentiful and good, especially Gooseberries. Strawberries are abundant, but rather small, which no doubt is attributable to the long spell of dry weather we experienced soon after the bloom was set. Nuts are over the average, and promise from present appearances to be very good.

Vegetables on the whole are very satisfactory. Early Potatoes were rather a light crop, but late varieties look very promising. Onions and Carrots are excellent, and quite free from the mite, which I attribute to spreading woodashes in the bottom of the drills previous to sowing the seed.—E. GILMAN.

Nostell Priory.—The fruit crops in this neighbourhood as far as Apples, Pears and Plums are concerned are disappointing. With such a profusion of bloom it was hoped there would have

been an abundance of fruit, but usually such a wealth of flowers is followed by a scanty supply. In the gardens here we have a nice average crop of Apples and Pears. Ribston Pippin, Cox's Orange, King of the Pippins, Cox's Pomona, Lane's Prince Albert, and some few others had to be relieved of a portion of their crop. Last year it was noted by many that the older trees were by far the most satisfactory; this year it appears to be the reverse. Of Pears, Jargonelle, Williams' Bon Chrétien, Louise Bonne of Jersey, Conseiller de la Cour, Beurré Diel, Victoria and Bergamotte d'Espéren are heavily cropped. Plums and Damsons I regret to say are a complete failure; even the reliable Victoria is but sparsely fruited. Apricots are good and set enormous crops, as also Cherries, both dessert and Morello. Gooseberries, Currants and Raspberries are plentiful; Raspberry Superlative is an enormous cropper, strong grower and resists drought better than any one I grow. Strawberries were good, especially the first pickings; later fruits were small and the crop soon over. Cottage gardens I regret to say are very thin of that the most valuable of all family fruits, the Apple.

Vegetable crops are satisfactory. Broccoli lasted well into June, then that excellent Cauliflower Veitch's Extra Early Foreign came in before the former was over and kept us going. Peas and Beans are good, but want rain. Potatoes are good, with no sign of the dreaded disease.—J. EASTLE.

Barkby Hall, Leicester.—Apples are good in this garden and fair average crops in the neighbourhood. The winter moth is not quite so troublesome in this neighbourhood as it was a few years ago. The Apple leaves have had a fungus which is somewhat like the scab fungus, but I have never known it to come so early before (June 12 when first seen), nor so prevalent. In this garden I sprayed with potassium sulphide, 1 oz. to three gallons of water, which prevented further mischief. Of Pears I had a good show of bloom, but fruit dropped very much after setting. The cold north winds seemed to be the cause in some cases. The crop on the whole is below average. Plums also bloomed splendidly, but did not set, owing to cold north winds apparently. The crop is almost a failure in this neighbourhood. Cherries are below the average, while Apricots and Peaches are excellent crops. Gooseberries and Currants (both Black and Red) are very heavy crops. Raspberries and Strawberries are good heavy crops. Greenly on fruit trees and Roses has been unusually abundant this year.

Vegetables, like most other things, are very late. Early Potatoes are rather light. Onions are good and free from maggot. Carrots are good, but the fly has been troublesome.—J. LANSDELL.

Chatsworth.—Generally speaking the fruit crops in this neighbourhood are good with the exception of Plums, which are very poor. Apples and Pears are an average crop; Cherries over the average; Gooseberries, Red and White Currants above the average; Black Currants and Raspberries an average crop; Strawberries above the average, and good fine fruit.

All kinds of vegetables are growing freely. Potatoes are looking very well. The early varieties are very good, with no signs of disease at present. The late kinds also are looking very well and give promise of a good crop.—Wm. CHESTER.

Hopton Hall, Wirksworth.—Strawberries President and British Queen are a good crop, though smaller than usual. Black, Red, and White Currants are grand crops. Gooseberry trees were broken down with the heavy crop. Of these I have planted out 1000 seedlings this spring. This crop has never failed me—mostly standard trees. They last about twenty-one years as standards; the same with standard Currants. Cherries Morello, May Duke, and Late Duke are good crops. Plums are very few, Transparent and Green Gages, Victoria, and Early Prolific being light crops. Damsons are a complete failure, though early prospects were good. Apples are a marvellous crop (except Lord

Sutfield, which is a complete failure); Lord Grosvenor is weighed down with fruit. Duchess of Oldenburg, Irish Peach, King of Pippins, Ecklinville, Potts' Seedling, Newton Wonder, New Northern Greening, New Hawthornden, Royal George, Bramley's, Warner's King, Worcester Pearmain, Margil, and others have very heavy crops. Raspberries are very good, especially Superlative; this variety is producing a fine late crop.

Potatoes are excellent. The old Walnut Leaf and Lemon Kidney have very good crops of specially good flavour. Onions are very good; Tripolis very fine. All Brassicas are very late.—GEORGE BOLAN.

Crewe Hall, Crewe.—Fruit crops on the whole are disappointing. There was plenty of bloom on nearly all fruit trees, and as there was not much frost nor severe weather in the spring it was hoped the crops would be very abundant, but as it is they are only moderate. Pears are about an average crop; Apples rather under; Peaches and Nectarines rather under; Apricots over; Strawberries and Raspberries hardly up to average, and fruit smaller on account of the dry, hot weather at the time of ripening. All small fruit is plentiful. Plums and Damsons are poor, and the trees, as with Cherries and some others, very much attacked by aphides, from which they are only now recovering.

Vegetables of all kinds are very good and plentiful. Potatoes are very healthy and bearing good crops of healthy tubers, with no symptoms of disease up to now.—Wm. WHITAKER.

Allerton Priory Gardens, Woolton, Liverpool.—Strawberries are a poor crop, but bush fruits and Raspberries are good. Apples and Pears are poor, and Cherries fair. The prevalence of bad weather with cold driving winds during the flowering period destroyed what promised to be an abundant set. The trees, Plums especially, have been badly attacked with insects.—J. J. CRAVEN.

Alfreton Park.—Fruit I am sorry I cannot say much for. Stone fruit is very poor; small fruits, such as Gooseberries, Currants, &c., are good; Pears poor. Apples here are very fair, but poor in neighbourhood.—G. M. KNIGHT.

Orton Hall, Peterborough.—Some of the fruit crops in this neighbourhood are very indifferent, others good. Of small fruits, Strawberries, Currants, and Gooseberries have been plentiful. The Black Currant mite, however, has made a difference with many. It appears worst on the Black Currant bushes that are overhung with other trees, such as the Plum and Apple. Black Currants I find this season are about double the price of the Red. Plums are a very scanty crop, especially in the open quarters; Nuts appear to be plentiful; Peaches and Apricots are a fair crop. Apples are not so plentiful as was anticipated from the abundant show of bloom, still there are fair crops of some kinds. Pears with me are much below the average; Duchesse d'Angoulême in the open has a fair crop, but Pitmaston Duchess on walls and in the open has scarcely any fruit.—A. HARDING.

The Gardens, Middleton Hall, Tamworth.—Apples are under average, but quality good; Pears under; Plums under, but good; small fruits plentiful; Strawberries average, good. In the early spring there was a bright prospect for a good fruit harvest, but the cold nights and late spring frosts entirely blighted those prospects.

The vegetables in general are good. Potatoes (early) have been very good, tubers free from disease; the late ones look well and good crops may be expected.—J. W. BROWN.

The Gardens, Shavington Hall, Market Drayton, Salop.—The fruit and vegetable crops in this district are very good generally speaking. Strawberries were a good crop, but failed to swell up satisfactorily on account of dry weather. Apricots have been a good crop. Among Apples, Lord Derby, Lord Grosvenor, Warner's King, Ecklinville, Hawthornden, and Dumelow's Seedling are well laden with fruit; Cox's Orange Pip-

pin, Ribston Pippin, King of the Pippins, Bismarek, &c., are carrying an average crop of fruit. Pears are good, especially Williams' Bon Chrétien, Marie Louise, Clapp's Favourite, Louise Bonne, Pitmaston Duchess, Doyenne du Comice, Beurré Diel, and Winter Nelis.—T. BENNETT.

Synnerton Park, Stone.—Apples, Pears, and Plums in this neighbourhood are a very poor crop; Damsons almost a failure; Cherries, Strawberries, Raspberries, and all kinds of Currants are most abundant.

Vegetables of all kinds have been very good, but are later than usual.—JAMES TURNER.

Mickleover Manor Gardens, Derby.—Strawberries and all kinds of bush fruit, including Currants and Gooseberries, are bearing very heavy crops. Apples are almost a failure; even Duchess of Oldenburg has but the tenth of a crop; Pears are almost a complete failure; Plums on standards are a failure, as last year; on walls there are a few in sheltered nooks. I notice a fair crop of Plums on some cottage gables in this neighbourhood.

Vegetable crops are good, especially Potatoes. Peas have been good, but soon over.—J. CAMPBELL.

WALES.

Margam Park Gardens, Port Talbot, South Wales.—Strawberries have been good here. The best were Royal Sovereign, Latest of All, and Leader; Monarch also did well, the fruits being very fine. Red Currants are very good; Black Currants a moderate lot; Gooseberries a fair crop; Raspberries a good crop. Apples are a moderate crop and the quality promises to be good. Pears are a very uneven crop; Plums a poor crop; Cherries (Morellos) are good; Peaches and Nectarines are very good.

Outside vegetables have been very good here and plentiful.—J. HOLLINGWORTH.

Wynnstay, Ruabon.—On the whole this season will, I believe, be a good one, and as we have at last got a welcome rain at time of writing I think we shall get better size in Apples and Pears than expected. Strawberries were a splendid crop and Royal Sovereign was well to the fore. Noble I shall discard, also Sensation and Competitor, in favour of the above-named.

Vegetables, taken on the whole, are good this year, the only exceptions with me being Parsnips and Carrots. Onions are grand, without a trace of maggot. A very cold spring has made us at least three weeks later with most things than usual.—F. FAIRBAIRN.

Bodnant Gardens, Tal-y-Cefn, R.S.O., Denbighshire.—With the exception of Apples I have good all-round average crops. Apples bloomed very well, but owing to a continuance of cold weather they failed to set well. Some trees on low walls are carrying heavy crops, likewise some others trained on the roof of a north shed.

Vegetable crops are very promising. Potatoes so far have turned out clean and heavy.—J. SAUNDERSON.

Gordding.—Apples and Pears are fair, some trees being well cropped. Of Apples, Alfriston, Cox's Orange Pippin, Ecklinville Seedling, Stirling Castle, Cellini Pippin, and Cox's Pomona are the best. Of Pears, Beurré Diel, Pitmaston Duchess, Williams' Bon Chrétien, Louise Bonne of Jersey, Marie Louise, and Conseiller de la Cour have good crops. Plums are scarce, also other stone fruit. Bush fruit is excellent; Strawberries medium crops. Many of the first fruits were disfigured through want of sunlight and so much dull, wet, cold weather at the time of flowering. The two best varieties have been Vicomtesse H. de Thury and Royal Sovereign. The latter should have an open situation and be planted 2 feet 6 inches each way, the leafage being so robust.

Vegetables are plentiful; early Potatoes a very heavy crop. Ringleader is much liked here, being very early. Late ones are looking promising. Kidney Beans, both dwarf and runners, were difficult to get a plant, the first sowing failing in

many places in this neighbourhood. The early part of May was too wet and cold for them. The second sowing is doing well, though a little late. All the Brassica family are doing well. Celery and all root crops are very promising.—W. COATES.

Slebech Park, Haverfordwest.—The fruit crops in this district are almost a complete failure this season, as wet, cold, stormy weather prevailed during the time that the trees were in bloom. We did not get frost, but had very low night temperatures with damp. Apples bloomed well, but I have very little fruit except on some young trees. Pears are also a very poor crop, although there was an abundance of good healthy bloom. Plums promised a grand crop. They were a mass of bloom and set well, and then dropped off, even the Victoria and the common Damson dropping almost every fruit. Small fruits and Strawberries were a splendid crop. Cherries, Peaches, and Nectarines are not much grown in this county.—GEORGE GRIFFIN.

Cardiff Castle.—The fruit crops in the gardens here, with the exception of Plums, are good. Many of the Apple and Pear trees are weighed down with fruit to the breaking point and the branches have had to be propped up with strong stakes to prevent them snapping off. The long-continued drought during the months of June and July experienced in this district was detrimental to the fruits swelling in the early stages of growth, and a great many dropped, greatly benefiting the over-ripened trees. The points of the shoots of Apple trees were badly infested with aphid this season, and the leaves were curled up and blackened to a degree which I have never seen before. But after the affected points were cut off the trees made fine clean growths, and now they are healthy and vigorous, and the rain we have had since the beginning of August has much improved the size of the fruits. Plum trees were covered with flowers, but the fruit did not set on the trees in the open quarters, and but sparingly on the wall trees, all of which have been badly crippled with aphid this year. The Strawberry crop was good, but, owing to the drought, of short duration. I grow a great many varieties here, but depend chiefly upon the following for producing good crops of excellent quality: Royal Sovereign, President, Vicomtesse Héricart de Thury, Gunton Park and Scarlet Queen.—A. PETTIGREW.

The Gardens, Gogerddan, Aberystwith.—Apples and Plums are an average crop; Pears under average; Cherries, Gooseberries and Currants are good; Damsons are very scarce. Apricots and Peaches are not grown in the open about here. Apples and Pears will be small and not up to the usual quality.

Vegetables are fairly good. Early Potatoes have been good and the late ones look well. Peas have been a good crop, also Cabbage, but vegetables in general are very late.—J. VEAREY.

Nevill Court, Abergavenny.—The season on the whole has not been good for outdoor fruit and garden crops generally. We had one of the finest shows of bloom on record on all kinds of fruit trees in this district, but the severe and cutting east winds destroyed the greater part of the bloom before it was well open, after which blight of all kinds, especially mildew and black aphid, followed, causing a great amount of labour and free use of insecticides to save any crop at all. In sheltered nooks in the valleys I have observed good crops of Apples and Cherries—more especially White Heart and Bigarreau. Apples bearing good crops on dwarf trees are Irish Peach, Quarrenden, Beauty of Bath, Duchess of Oldenburg, Red Astrachan, Wormsley Pippin, Beauty of Stoke, Albany Park Nonsuch, Welford Park Nonsuch—in fact, all sorts on bush trees are bearing well. Apples on standards are under average; Pears and Cherries are over average; Peaches, Nectarines, Apricots, and Plums are all under average; Nuts of all kinds are abundant and good; Raspberries abundant and good; Strawberries excellent; Gooseberries, Black, Red, and White Currants are good crops. Of Straw-

berries, Veitch's Perfection, Monarch, Lender, Royal Sovereign, President, Noble, Sir J. Paxton, Sir Charles Napier, and Waterloo have been excellent.

The crops in the kitchen garden are later this year owing to the cold spring and east winds, which were very keen. Early Potatoes are turning out well, but they are smaller than in previous years owing to lack of rain. Sharpe's Victor, Old Ashleaf, Veitch's Improved Ashleaf, and Ring-leader have been especially good; Early Puritan is now turning out good tubers, of excellent quality and size. Cauliflowers Extra Early Forcing and The Pearl are excellent for early work. Autumn Giant and Self-protecting, as well as Brussels Sprouts, Kale, and late Broccoli, are looking excellent. French and Runner Beans were later this year, but they are now abundant and good. Veitch's Early Favourite is the earliest French Bean I know. Onions, Parsnips, Carrots, Turnips, and Beetroot are looking well in every way and free from maggot. Stanstead Park Cabbage Lettuce is excellent to sow in autumn for an early spring supply. There is no better Lettuce than a good strain of the old Tom Thumb Cabbage Lettuce for a summer supply.—JOHN CHINXERY.

SCOTLAND.

Carron House, Falkirk.—There never was a finer promise of fruits throughout my sixteen years of experience in this locality than during the past spring, every bush and tree being loaded with blossom and mostly every species set abundance of fruit, but the cold and sunless weather of May and June did much to blight one's prospects. The nights were very cold, and the thermometer was often down to the freezing point in early morning. Notwithstanding such untoward weather, there is on the whole abundance. Apple trees have shed much of their crop, but plenty remains. Plums of the hardier sorts are a fair crop; Morello Cherries abundant; Red and White Currants, which have been lifted and replanted several times, have a heavy crop of fine fruit. Black Currants suffered severely from the frost on the night of May 15, but where the sun did not strike on them in the early morning they suffered less. The same may be said of Gooseberries and Strawberries. Having tried many varieties of the latter, I find that it would be waste of ground to retain some of those which are lauded for their excellence by many cultivators. John Ruskin is the earliest which I have tried, but is soon over. Royal Sovereign was a week later than the former, but the fruiting period is of short duration. Were I to grow only two sorts they would be Vicomtesse Héricart de Thury and President. These two along with Elton Pine are favourites in most districts of Scotland. Some sorts which I grew in England with much satisfaction are almost worthless in Scotland.

This is one of the best vegetable seasons I have known in the north. Potatoes have looked well from their earliest appearance above ground, excepting some of the first crops, which were cut down to the surface of the soil by the severe frosts in May. The kidney varieties are a fine crop, but much smaller than usual. Veitch's and Belvoir Kidneys are the best this season; Sutton's A 1 is first-rate in every respect; Early Regent is very good; Snowdrop is, as in former years, a special favourite, and comes much the same as Sharpe's Victor, but, of course, much later. All the Brassica crops have been satisfactory. Cabbages are the best I ever had. Six sorts planted on unbroken ground (after Onions) were unusually fine, with an absence of outside leaves. Broccoli treated in this way also did capitally. Onions were never more promising; both autumn and spring sowings on trenched heavy ground are all I could wish. Cauliflowers have been fair, but some of the earliest sorts have come in prematurely. Roots generally are barely equal to what they are in some seasons. The continuous winds have dried up the ground very much, but

the damp nature of the soil has not yet suffered by drought. In some gardens which are elevated and the soil light, rain is much wanted. Where trenching is well done there is little to complain of. Poor and shallow land is much in want of moisture. Field crops never looked better. Turnips are excellent.—M. TEMPLE.

Dunrobin Castle, Sutherland.—Fruit, flowers, and vegetables are ten days to a fortnight later than usual. Some of the earlier-blooming fruits were a good deal injured by the inclement weather in May. Early Strawberries, particularly Royal Sovereign, were a failure. Late kinds did well, particularly Elton Pine. Most of my supplies were obtained from this trustworthy old kind, and at this date (August 18) it is still in bearing, and will be for a fortnight to come. Raspberries have done well, particularly Superlative, which is an undoubted acquisition. Black, Red, and White Currants are plentiful and good; Pears scarce; Plums under average. There are good crops of Apples on some trees, mostly late-blooming kinds.—D. MELVILLE.

The Hirsell, Coldstream.—As to the fruit crops here I never saw a more encouraging outlook while the trees were in blossom, but especially in regard to Pears. At the most critical time, from the beginning to the middle of May, we had a spell of cold, sunless weather, as much as 6° frost, which did a lot of mischief. Apples, being later, did not suffer so much. The same remark applies to the other fruit crops. The results to date are thus: Pears are average; such sorts as Bcurré Diel, Bcurré d'Amauldis, Williams' Bon Chrétien, and Doyenné du Comice have over-average crops. Apples are over an average; such sorts as Manks Codlin, Stirling Castle, Ecklinville, Lane's Prince Albert, and Devonshire Quarrenden will require to be thinned. Plums are an average crop; Rivers' Early Prolific, The Czar, and Victoria have full crops. Cherries are an average crop, Morellos being over. Small fruits are most abundant. Owing to the dry weather Strawberries had but a short season.

Vegetables have done fairly well considering the season we have had. A cold May and severe drought till now were two very important factors that had to be faced. The former difficulty is not easily got over; the latter is made less harmless by heavy manuring and deep cultivation where the ground will admit. Deep trenching is the sheet-anchor of good vegetables. I have had over-average crops of Peas, Cauliflowers, Potatoes, and such-like crops.—J. CAIRNS.

Terregles, Dumfries, N.B.—The fruit and vegetable crops in this district are on the whole giving a fairly good return. The weather during March, April, and May was very unfavourable for the growth of early vegetables, and after an unusually mild winter excessive rains set in early in spring accompanied with a cold, damp, fluctuating temperature, which retarded the growth of early crops and to some extent damaged the fruit trees and bushes all over the western districts of Scotland. A great improvement in the weather took place during the first fortnight in June, and early crops made rapid progress, but such important things as early Potatoes, Cauliflowers, Cabbages, Carrots, Peas, Spinach, &c., were quite two weeks late in coming into use. Both field and garden Potatoes look well everywhere, and the only complaint I hear of is that very early varieties have given a light return this year. The prospects are that the main crop and later kinds will make good the deficiency. Growers, however, are not likely to command such good prices this year as compared with last. In this immediate neighbourhood we have had very little rain during the month of July, and at this date crops are suffering very much from the continued drought. Apples and Pears will give nothing more than an average return of fruit in this district, while Peaches, Nectarines, and Apricots are a very thin crop. Plums are a good crop all over. Wall-trained trees especially are giving an extra fine return. Small fruits, including Raspberries and Strawberries, are a splendid

crop, and with the dry weather we have had they are being gathered in excellent condition.—
JOHN MACKINNON.

TREES AND SHRUBS.

CARPENTERIA CALIFORNICA.

THIS, botanically related to the Mock Oranges, we fear is not a perfectly hardy plant except in such favoured spots as the Isle of Wight, the Devon and Cornish coasts, and the warm and southern parts of Ireland. It is one of our more uncommon shrubs that may be successfully grown and flowered in pots, and where kept in a greenhouse temperature it blooms as a matter of course earlier than in the open ground. In

the open ground or trained to a wall, it is, of course, seen to greater advantage than when confined in pots; still, where not quite hardy there is no reason why it should not be grown and flowered under glass in the manner described. Now that this has become well distributed about the country, it would be useful to hear from growers of it in different parts as to its behaviour, more especially in reference to its hardiness. The present season is the best for propagating this *Carpenteria*, for cuttings of the young growing shoots, if put into pots of sandy soil, will with ordinary care and attention root readily enough. The frame must of course be kept close and shaded till the cuttings strike. An ordinary cold frame is very useful if set apart for the propagation of hardy shrubs during the summer months, for a great many of

American home assumes the character of a small tree 20 feet or more in height. Specimens of this size or nearly so may be occasionally met with on this side of the Atlantic, and very picturesque they are. This *Rhus*, when not more than a dozen feet high, is essentially a tree, with a clear stem and rather wide-spreading head of irregularly disposed branches, round the points of which the large deep green pinnate leaves are arranged. The flowers are borne in dense terminal spikes standing clear of the handsome foliage, and just now these spikes, which are a kind of velvety red, form a very noticeable feature. They remain in this state a considerable time, and even in the winter when devoid of foliage these flower clusters give to the tree an uncommon appearance. Besides its natural habit of a small tree this *Rhus* also readily lends itself to another totally different mode of treatment, and that is, if a bed is filled

Carpenteria californica in a Devonshire garden. From a photograph sent by Mr. R. Kelly, Kelly, Lifton, Devon.

the spring, when the majority of outdoor shrubs are only just pushing forth their leaves, a specimen of this *Carpenteria* studded with its large white blossoms is not only a very beautiful object, but quite distinct from its other associates in the greenhouse. It may be kept in health for years in a pot, provided it is after flowering hardened and plunged outside during the summer months and well on into the autumn. If kept under glass altogether, the foliage is very liable to be attacked by red spider, which soon causes it to wear a sickly look. The heavy dews so prevalent in early autumn seem to benefit this *Carpenteria* greatly when it is grown in pots, and for this reason it should not be taken under cover before it is absolutely necessary. Treated as a shrub in

our most beautiful kinds may be struck from cuttings of the young growing shoots, taken just as they have lost their more succulent character and become moderately firm.

Mr. R. Kelly, Kelly, Lifton, Devon, who kindly sent us the photo from which the illustration was prepared, writing to us, says:—

The *Carpenteria californica* is 6 feet high and 7 feet wide. It is growing against a south wall, and was planted in its present position six years ago.

The Stag's-horn 'Sumach' (*Rhus typhina*).—Several species of *Rhus* are entitled to a place among our ornamental shrubs, and in nearly the whole of them the leaves die off very brightly tinted. One of the largest members of the genus is the Stag's-horn Sumach, which in its North

with young vigorous plants and they are cut back hard each year, and the young shoots limited to one or two, very large leaves will be produced, and the effect will be equal to any sub-tropical subjects that require heat and attention throughout the winter. When cut back in this manner some of the shoots will flower, but of course not so freely as in the case of old established tree-like specimens. *Rhus typhina*, in common with several other members of the genus, may be readily increased by means of cuttings of the roots, which soon form plants that grow away freely.—H. P.

A Laburnum avenue.—I lately at Cromer saw an avenue made entirely of Laburnums. The variety was the common *L. vulgare*, growing on stems 6 feet high, the growths trained to a single stout wire arched over a path 8 feet wide. The

plants were 4 feet apart, twenty on each side. The archway was, therefore, 80 feet long. Judging from the quantity of seed-pods hanging from the branches, this archway must have presented a glorious picture when the Laburnum was in bloom. At present the archways have got nicely covered, and as growth proceeds, which from the healthy appearance of the plants is rapid, a system of spur-pruning the side shoots will be necessary to restrict the growth and preserve the individuality of the trees.—E. M.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 20.

At the meeting held on Tuesday there was no falling-off in the exhibits, the hall being filled from end to end, several of the groups being rather too crowded, thus spoiling their effect in a great measure. Hardy flowers, considering the season we have just passed through, were excellent. The Dahlias of every section and Gladioli were well represented, while the display of Roses was wonderful. The groups of *Acalypha hispida* and *Salvia splendens grandiflora* showed the value of these two plants. Fruits, too, were well represented, vegetables also being well to the fore.

Orchid Committee.

Awards of merit were adjudged to the following—

CATLEYA INTERTEXTA (C. Mossii × C. Warneri).—The sepals and petals are of fine form and substance, pale rose, suffused with a darker shade towards the centre, lip rich velvety crimson, margined with pale rose, the side lobes rose, suffused with crimson, lined at the base with bright yellow lines. It is a most distinct and desirable variety, and worthy of every consideration. From Messrs. J. Veitch and Sons, Ltd.

LÆLIA SPLENDENS (L. purpurata × L. crispa).—In this the sepals and petals are pale rose, much crisped at the margin, the front lobe of the lip wholly crimson-purple, heavily fringed and margined with white, the side lobes white, becoming suffused with yellow, lined and suffused with deep purple at the base. It is similar in many respects to L.-C. exoniensis, but is longer in the front lobe of the lip and altogether finer than that variety. Messrs. J. Veitch and Sons.

MILTONIA BINOTI.—A supposed natural hybrid between *Miltonia candida* and *M. Regnelli*. The sepals and petals are buff, with large light brown blotches and a suffusion of rose at the base; the lip, fairly intermediate between the two species from which the hybrid is supposed to have been derived, is pale lilac, suffused with purple, and veined with a darker shade of colour. It has five raised light-coloured ridges at the base, the centre one being yellow. It is of free habit and a most distinct and desirable form. From Sir T. Lawrence, Bart., Burford Lodge, Dorset.

MILTONIA LEUCOGLOSSA.—This is one of the most distinct hybrids we have seen. The sepals and petals are greenish white, spotted with violet-purple. The large open lip is pure white except at the base, where it has a violet-purple suffusion on either side of the yellow ridged disc. In habit it resembles *M. spectabilis*, and is probably a hybrid between that species and *M. candida*. From Sir T. Lawrence.

Messrs. J. Veitch and Sons, Ltd., sent a choice group. In the back row were finely flowered *Oncidium Marshallianum*, a good form of *O. tigrinum*, and a lovely dark form of *O. crispum* with remarkably large flowers. *O. incurvum* was also well represented. The most prominent among the Cattleyas were *C. Warscewiczii*, with three spikes of flower, and a dark form of *C. labiata*. The hybrids, as usual, were well represented, the most distinct being *C. Chloris* (*C. Bowringiana* × *C. maxima*), in which the sepals and petals are delicate lilac, the lip rose at the margin, becoming veined and suffused with crim-

son-purple towards the centre and through the throat. *C. Wendlandiana* (*C. Warscewiczii* × *C. Bowringiana*) has the intermediate characters of both parents, the sepals and petals bright rosy lilac, the front lobe of the lip rosy crimson, becoming suffused in the centre with a darker shade of colour. It has the yellow eye in front of the throat as seen in *C. Warscewiczii*. *C. porphyrophlebia* (*C. intermedia* × *C. superba*) is a pale form with a deep rose-tinted lip. *Lælio-Cattleya Nysa* (*C. Warscewiczii* × *L. crispa*) was represented by six plants, each plant differing in a remarkable degree both in shape and the darker colouring of the flowers. *Coelogyne Veitchii* bore three spikes of its pendulous pure white flowers. Several finely-flowered *Miltonias*, *Dendrobiums*, and *Cypripediums* in variety, both of species and choice hybrids, were also included (silver Flora medal). Messrs. Hugh Low and Co., Bush Hill, Enfield, sent a choice group, consisting of dark forms of *Vanda cœrulea*, finely-flowered *Oncidiums*, several dark forms of *Cattleya Loddigesii*, *C. velutina* with two spikes of flowers, and a good form of *C. porphyrophlebia*. In *Lælio-Cattleya Pallasii* the sepals and petals are pale rose, marbled with white, the lip rich crimson-purple except through the throat, where it is prominently lined with yellow. *L.-C. intermedio-flava*, raised from the species indicated in the name, has the sepals and petals pure white, the lip creamy white, suffused and lined with rich rose-purple. Among the *Cypripediums* were good forms of *C. Sanderianum*, *C. Harrisianum superbum*, *C. Chas. Canham* with three flowers, good forms of *C. picturatum*, and *C. Charlesworthii* (silver Banksian medal). Messrs. F. Sander and Co. sent *Odontoglossum grande*, *Cypripedium purpuratum*, and two plants of *Dendrobium atro violaceum*.

Mr. C. H. Fielding, Southgate House, Southgate, was awarded a silver Banksian medal for a large group, consisting of about forty finely-flowered plants of *Dendrobium Phalaenopsis*, the colours varying from light rose to rich rose-purple, with crimson-purple lips. The plants were finely grown and the flowers fine in substance and form. A fine plant of *D. bigibbum*, several forms of *Cattleya Gaskelliana*, good forms of *C. Loddigesii*, and various hybrids and species of *Cypripediums* were also included. Sir T. Lawrence sent a fine plant of *Oncidium longipes* with ten spikes of its small yellow and dark brown flowers; and *O. trulliferum*, a miniature-flowered variety, with thick clustered spikes of yellow and small brown spotted flowers. A fine plant of *Miltonia spectabilis* with twelve flowers was awarded a cultural commendation. A dark form of *M. Moreliana*, good forms of *M. Clowesi*, and a grand form of *M. Blunui* var. *Lubbersiana* were also sent. Mr. J. Coleman, Gatton Park, Reigate, sent a dark variety of the natural hybrid *Cattleya Hardyana*. Mr. C. L. Ingram, Elstead House, Godalming, had *Lælio-Cattleya T. W. Bond* (*C. labiata* × *L. purpurata*), a lovely hybrid, sepals and petals pale lilac, the large lip pale rose in the centre, becoming suffused with rich crimson-purple and veined with a darker shade of colour, the side lobes rose, suffused and lined with yellow at the base. Mr. J. W. Moore sent a dark form of *Vanda cœrulea*, and from Frau Ida Brandt, Zurich, came cut spikes of *Angraecum Ellisi* and *Odontoglossum Lindleyanum*.

Floral Committee.

The following novelties obtained first-class certificates:—

PANDANTIS SANDERII.—This may be described as a greatly improved form of *P. Veitchii*, quite surpassing the old kind in the more distinct and golden variation, which in the old kind is of a silvery hue. This variegation is very telling, and, judging by the examples shown, is equally retained in large and small specimens. From Messrs. Sander and Co., St. Albans.

LIGISTRUM WALKERI.—What this species may be when large plants are secured is difficult to determine. In our opinion the plant is by no means attractive in its present form, and, as we

know, such things are valueless from a flowering standpoint. The plant differs from others of its race by a more tree-like form, i.e., an erect central growth with twiggy branches, on which latter the small green undulated leaves are alternately placed. From Messrs. Paul and Son, The Old Nurseries, Cheshunt.

The following obtained the award of merit:—

CHRYSANTHEMUM LOUIS LEMAIRE.—An early-flowering form of which only flowers were shown. We have, therefore, no clue to habit, height, general freedom or decorative value. The colour is bronze and yellow, the former largely predominating. From Mr. Wells, Earlswood, Redhill.

CHRYSANTHEMUM MAY MAUSER.—A pure white kind, which if a *bout-jarde* early kind will prove of much value. It is somewhat inclined to the reflexed type. From Mr. H. J. Jones, Lewisham.

POPULUS ONTARIO VARIEGATA.—A golden variegated form of the well-known Ontario Poplar. From Mr. J. Carter, Willow Bank, Keighley.

ADIANTUM FAULKNERI.—No group of Ferns is more diversified than the *Adiantums*, yet this kind compares with none of them. It is an especially graceful and elegant kind, the pinnae small, yet not so minute as in *A. gracillimum*. In colour it is of the yellow-green shade. A small group was shown, the whole being quite uniform in size and colour. From Mr. T. Rochford, Turnford Hall Nurseries, Broxbourne.

ACER JUBILEE VARIEGATUM.—A distinct and well marked plant, in which the variegation is white, rather blotched or marbled than otherwise. From Messrs. Paul and Son, Old Nurseries, Cheshunt.

ALTHEA (HIBISCUS) TOTA ALBA.—A plant too well known to need description here, the variety being represented by a small handful of about half-a-dozen sprays. From Messrs. Paul and Son, Cheshunt.

CYNERIUM ARGENTÆUM ATREO-LINEATUM.—One of the most elegant and beautiful plants we have seen, the habit generally smaller and the leaves narrower than in the type, the leaves arching so that the tips reached the ground. From Messrs. J. Veitch and Sons, King's Road, Chelsea.

DAHLIA COUNTESS OF LONSDALE (Cactus).—A distinct and novel kind, in which orange-salmon and pink are combined. From Messrs. Keynes, Williams and Co., Salisbury.

DAHLIA PROGENITOR (Cactus).—A crimson-scarlet, having the tips of the florets split into several divisions, giving a forked or horned appearance to the flower. From Messrs. Keynes, Williams and Co.

DAHLIA VISCOUNTESS SHERBROOKE (Cactus).—A finely formed flower of an orange-scarlet hue. Messrs. Keynes, Williams and Co.

DAHLIA THE CLOWN (Cactus).—This is also of an orange-scarlet tone, and tipped heavily with white. Messrs. Keynes, Williams and Co.

DAHLIA THE DUKE (Pompon).—A prettily formed flower of a ruby-crimson shade. From Messrs. Keynes, Williams and Co.

DAHLIA WATCHMAN (Fancy).—Deep yellow, flaked with crimson and scarlet. From Messrs. Keynes, Williams and Co.

DAHLIA WILLIAM NEATE (Show).—A flower in which the predominant red-orange tone is shaded by a delicate fawn. From Messrs. Keynes, Williams and Co.

DAHLIA ANTELOPE (Cactus).—A good self of capital form, and ruby-scarlet in colour. From Messrs. J. Burrell and Co., Cambridge.

DAHLIA LUCIUS (Cactus).—A striking flower of a decided shade of scarlet-orange. From Messrs. J. Burrell and Co., Cambridge.

DAHLIA IRIS (Pompon).—A salmony yellow, tipped with a very delicate lilac tint. From Mr. C. Turner, Slough.

DAHLIA CLARABEL (Pompon).—A medium-sized flower of a pure shade with white base. From Mr. Chas. Turner, Slough.

DAHLIA LESLIE SEALE (Single).—A flower of medium size, rose colour, with heavy crimson base. From Mr. V. Seale, Sevenoaks.

DAHLIA SNOWFLAKE (Pompon).—Very pure white, of good form. From Mr. V. Seale.

DAHLIA DISTINCTION (Pompon).—A very distinct flower, ruby-red in colour and compact in form. From Mr. V. Seale.

DAHLIA DEMON (Pompon).—A pretty flower of excellent form, and rich self crimson in colour. From Mr. V. Seale.

DAHLIA DAVID JOHNSTONE (Show).—Pale salmon buff, delicately suffused with lilac-purple, particularly in the younger stages of the flower: a most distinct kind. From Mr. G. Humphries, Chippenham.

DAHLIA RANJI (Cactus).—An exceptionally dark flower, the predominant shade being blackish maroon, the tips of the florets wine colour. It is also good in form and not too large. From Mr. G. Humphries, Chippenham.

On this occasion one of the most varied and interesting collections was that from Messrs. Paul and Son, The Old Nurseries, Cheshunt. In this lot the Roses were an especial feature, particularly good being *Perle des Jardins*, *Mme. Hoste*, *Mme. P. Cochet*, *W. A. Richardson*, *Maréchal Niel*, *Caroline Testout*, *Augustine Guinoisseau*, the white form of *Rosa rugosa*, as also the double white *De Coubert*, *Bardou Job*, and many more. Very good, too, were the *Cactus Dahlias*, these embracing all the best known kinds. A few of the best of the *Cactus* kinds were *Mrs. Webster*, *Gloriosa*, *Miss Box*, fine crimson; *Mrs. C. Turner* and *Lady Penzance*, both fine yellows; the old *Juarez*, still a good flower; *Harmony*, and *Starfish*. A nice lot of the pompon kinds was also set up, the whole fresh and well grown and pleasingly arranged. Many interesting plants were here also, notably some handsome baskets of *Meadow Saffrons* in variety, these latter including the well-known *C. speciosum*, *C. tigrinum*, *C. byzantinum*, *C. maximum*, &c. A fine lot of the new *Physalis Franchetti* was noticeable. Other good showy things included *Rudbeckia Newmani*, *Aster bessarabicus*, *Montbretia crocosmia-flora*, a capital bunch of *Senecio pulcher*, and the pure white *Anemone Lady Ardilaun*. Flowering sprays of *Erythrina crista-galli* taken from a plant forty years old and from the open air proved the hardy character of this showy subject. Several large baskets were filled with flowering examples of *Cyclamen hederifolium*. *Phlox Etna* and *P. Coquelicot* were the brightest of scarlet shades. Other things of more than passing interest were *Clematis coccinea*, *C. Duchess of Albany*, one of the *C. coccinea* hybrids, and the very distinct *C. graveolens*, with its small, though decidedly yellow flowers. A silver-gilt Flora medal was awarded. Another attraction at this meeting was the magnificent collection of cut spikes of *Gladiolus*. Many of the spikes carried a dozen fully developed blossoms, the first and last being apparently of a uniform freshness, so admirably were they got up. This fine exhibit came from Messrs. J. Burrell and Co., Cambridge. There were nearly 200 spikes of these showy flowers. There were many named sorts, but the best spikes were to be found in the numerous seedlings staged, a fact alone bearing the highest testimony to the strain grown by the Cambridge firm in question: and when we further state that nearly, or quite, one half of this group was made up of unnamed seedlings, the quality of the latter will be more fully apparent. The one end of this group was finished with *Cactus* and pompon *Dahlias* in variety, the other end with the hardy hybrid forms of *Gladiolus Lemoinei* (silver-gilt Flora medal). From Crawley, Messrs. J. Cheal and Sons brought a fine all-round exhibit of *Cactus* and pompon *Dahlias*, also a smaller lot of show kinds. These included all the leading kinds of those now in commerce. A few good ones are *Cycle*, *Duchess of York*, *Harmony*, *Fusilier*, *Fantasy*, *Lady Penzance*, *Miss Webster* (very pure white), *Mrs. C. Turner* (fine yellow), &c. The singles in this group were very fine, the flowers singularly fresh and good in form, and of the right size (silver Flora medal). Messrs. Wm. Paul and Son, Waltham Cross, set up a grand exhibit of cut *Roses* that

showed the resources of the firm where these flowers are concerned, quite one half of one of the centre tables being occupied with beautiful flowers, many being in very good form. Those shown included representatives of all sections, and these, too, in good substantial gatherings. Others, again, were in baskets, and, again, larger lots in boxes, and so forth. A few of the most telling were *Mrs. Grant*, *La France*, *Navier Olibo*, *Mme. P. Cochet*, *Maman Cochet*, *Marquise Litt*, *Mme. Hoste*, *Perle d'Or* (an exquisite lot of buds and blossoms), *Alfred Colomb*, *Marie van Houtte*, *Caroline Testout*, *Queen Mab*, *Enchantress*, *Mme. de Watterville*, *Souv. de Catherine Guillot*, *W. A. Richardson* (beautiful and rich in colour), *Sylph*, *Francisca Kruger*, *Niphetos*, the lovely *Empress Alexandra of Russia*, and many more (silver Flora medal). *Mr. Leopold de Rothschild*, *Gunnersbury House*, *Acton* (gardener, *Mr. Jas. Hudson*), sent a dozen splendid examples of the new *Acalypha hispida* (*Sanderi*) set in a thin ground of *Maiden-hair Ferns*. The plants were about 3 feet high, grown to a single stem, and carried an almost endless number of the rosy crimson inflorescences. Grown in this way, the ample leafage on long petioles acts as a sort of support to the inflorescence, which, by being borne over it, produces a distinctly graceful result. The rapidly increasing number of these coloured appendages, with the colour so long retained, renders them of the greatest value in decoration. From the same gardens also came a fine group of the brilliant *Salvia splendens grandiflora*, the plants raised from seedlings and cuttings, and flowered abundantly. Most of the plants were between 4 feet and 5 feet high (silver Flora medal). *Ferns* were again represented by a large assortment of *Davallias* from *Mr. H. B. May*, *Lower Edmonton*, who had got together some fifty species and varieties of these *Ferns*, many of which possess exceedingly graceful fronds difficult to describe in detail without the use of many technical terms. A few of the more distinct are *Davallia fijiensis*, *D. f. plumosa* (very fine), *D. f. effusa*, *D. f. gracillima*, a most elegant kind; *D. f. major*, *D. f. robusta*, all pleasing and graceful in their delicate fronds; *D. ornata*, *D. hirsuta*, *D. madagascariensis*, *D. Griffithiana*, *D. Mooreana*, a most useful plant; *D. tenuifolia Veitchi*, of a yellow-green tint, and with singularly small pinnae that give an impression of being partly suppressed till a close view is obtained. In this group the beauty and value of the many forms of *D. fijiensis* with their dark and heavy fronds in some instances is especially noteworthy (silver-gilt Banksian medal). Then from *Earlwood* what may be taken as the first representative exhibit of early *Chrysanthemums* was set up by *Mr. W. Wells*, and included a large number of mostly well-known kinds, the whole arranged in tree bunches. Very good were *Mme. Marie Masse* and *Edmund Duval*, a good white, which with *Market White* and *Mychett White* form a trio of good things all early and free. *Queen of the Earlies*, *Mme. Liger Ligneau*, yellow; *M. Zephir Lionnet*, orange-yellow; *Jeanne Vaillermet*, crimson-chestnut; *Harvest Home*; and *Ambroise Thomas*, red-orange, were among the best. Many pompons were also included, such as *Longfellow*, *Golden Flecco*, *La Petite Marie* and *Toreador*, a neatly formed flower of a red-orange and yellow shade (silver Banksian medal).

From the *Hale Farm Nurseries*, Messrs. T. S. Ware and Co., Ltd., brought a fine lot of *Cactus* and other *Dahlias*, that included some exceedingly fine and well-grown blooms, unfortunately too much crowded. The flowers were simply a densely-arranged bank in which of necessity many colours clashed. The blooms, however, were in every way excellent, and the condition of the exhibit in question was due to the generally crowded state of the hall on this occasion, which was full to overflowing. Apart from the exhibit of *Dahlias*, which was one of the most comprehensive at this meeting, was a good assortment of *Cannas* in many leading sorts, while here and there various grasses, *Bamboos* and sprays of *Asparagus* afforded some slight

relief to the great mass of colour in the flowers (silver Banksian medal). Another group of *Chrysanthemums* in pots from *Mr. J. Witty*, *Nunhead Cemetery*, was arranged near the entrance in half-circular fashion. There were some good flowers in this group, but we have no sympathy with the hoisting up of pots of *Maiden-hair Fern* to the very level of the flower-heads so frequently practised in this case. The foliage in well-grown *Chrysanthemums* is not only the most natural in such a case; it is also the best foil for the flowers, which are rarely too thickly placed when the pots are used in which the plants have grown. Varieties of *Mme. Desgrange* were frequent, also pompons and other early sorts, together with a plant of a so-called hairy kind—no names were attached—(silver Banksian medal). From *Mr. Chas. Turner*, *Royal Nurseries*, *Slough*, came some three dozen sorts of the best *Cactus Dahlias*, the flowers fresh and bright-looking, arranged in an open and free manner, so that individual worth could be seen. *Lady Penzance* and *Mrs. Chas. Turner* were especially fine, as also *Miss Webster*, *Beatrice*, *Night*, *Ethel*, *Alfred Vasey*, and many others; a few good hybrid pompons were also shown (silver Banksian medal). Another fine lot of *Dahlias* came from *Mr. S. Mortimer*, *Farnham*, *Surrey*. In this case, however, a large number of show and fancy as well as *Cactus* kinds was shown, the former of excellent finish and in considerable variety. The *Cactus* varieties were arranged in fan like bunches behind and as a central block, and in this way made a very effective arrangement (silver Flora medal). From *Mr. J. G. Foster*, *Brockhampton*, *Hants*, came a capital exhibit of *Sweet Peas* for so late a date; the varieties, however, included nothing fresh in these flowers so far as variety is concerned (silver Banksian medal). *Cannas* were sent in some twenty varieties from the garden of *Lady Freake*, *Fulwell Park*, *Twickenham*, the spikes having been cut from plants in the pleasure ground, and for this method of culture, in so trying a year, were very good (bronze Banksian medal). The Messrs. *Veitch and Sons*, *Chelsea*, as usual contributed a small series of flowering shrubs, in which were several varieties of *Hibiscus*, such as *H. de la Veuve*, rose, lilac and crimson; *H. elegantissimus*, white, crimson, and pink; *H. Comte d'Hainaut*, white and crimson, inclined to doubling; the pretty blush-flowered *Abelia rupestris*; *Bignonia grandiflora*, with orange-scarlet flowers; *Caryopteris mastacanthus*, a pleasing shrub, with pretty blue flowers in axillary clusters; *Gynerium argenteum albo-lineatum*, an erect-growing *Pampas*, with narrow leaves, lined white; and *G. a. Rendatleri*, a splendid example, sending forth its silvery plumes to a height of 9 feet or more. Of these handsome plumes there were about two dozen, in varying stages of development, which for the size of the root-stock would indicate a remarkable freedom of flowering. The plant possesses a fine vigorous habit withal.

Fruit Committee.

The fruit committee had its full share of exhibits, much space being taken up with collections of Apples and Pears. We fail to see what advantage there is in showing fruit that will be in season next spring, and which would have been better left on the trees for another month. Let the fruit that is shown be ripe and in season, and then some good will be done and lessons as to the value of the varieties and their season of ripening taught. What good, for instance, does showing *Bramley's Seedling* in September do? Grapes were more numerous than usual, not large bunches, but well coloured. The new perpetual *Strawberry St. Joseph*, from *Gunnersbury House*, was an interesting exhibit.

An award of merit was given to—

STRAWBERRY ST. JOSEPH.—An excellent medium-sized fruit of a pale red colour, flesh firm, and with a brisk refreshing flavour. This is a most useful variety, as it prolongs the *Strawberry* season, the newly-made runners bearing fruit freely, thus making it a valuable autumn kind.

Both parent plants and runners of this summer's growth were showing fruit in quantity. From Mr. J. Hudson, Gunnersbury House, Acton; Messrs. G. Bunyard and Co., Maidstone; and Messrs. Cannell and Sons, Swanley.

Messrs. Wm. Paul and Son, Waltham Cross, sent a collection of fruit trees in pots. The Peaches were very fine, as were the Figs and Apples; such kinds as Bramley's, King of Tompkins Co., Bismarck and Lord Derby were excellent. In the front of the group was a collection of Apples, gathered fruits. The best was Lord Suffield. Peasgood's Nonsuch, Lord Derby, Lady Henniker, Blenheim Orange, Cellini, The Queen, Warner's King, Pott's Seedling and Stirling Castle were also very fine (silver gilt Knightian medal). Messrs. Laing and Sons, Forest Hill, staged 100 dishes of Apples and Pears. This firm had the best Pears in the hall, the fruits being specially fine for the season. Souvenir du Congrès was excellent, as were Duchesse d'Angoulême, Pitmaston Duchess, General Todtleben, Durondeau, Marie Louise, Bon Chrétien and Louise Bonne of Jersey. Of the cooking Apples, Hollandbury, The Queen, Bramley's, Lord Derby and Bismarck were the best; while of the dessert varieties, Barnack Beauty, Duchess of Oldenburg, Gravestein, and Lady Sudeley were excellent (silver gilt Knightian medal). Messrs. Peed and Sons, Roupell Park Nurseries, had 100 dishes of fruit nicely arranged. There were Grapes at the back, the varieties being Gros Maroc, Alicante, Golden Queen, and Muscat of Alexandria. The Apples were mostly well-known kinds and good. Cellini was good, as were Tyler's Kernel, Lady Henniker, Queen Caroline, Chelmsford Wonder, Lord Derby, and Wealthy. Dessert varieties were good, though not quite so large as usual. Pears were also of good size (silver Knightian medal). A most interesting collection of fruit came from Mr. G. Kelf, South Villa Gardens, Regent's Park, including Grapes, not very large bunches, but the berries well coloured, the varieties being Muscat of Alexandria and Alicante, six bunches of each. A very good bunch of *Musa Cavendishi*, Melons Blenheim Orange and Holborn Favourite, Plum Golden Drop, and Tomatoes in variety were here included (silver Knightian medal). Mr. W. Roupell, Harvey Lodge, Roupell Park, S.W., brought an interesting collection of fruit to illustrate the lecture. There was a nice lot of Figs in pots in a small state, these having been grown in the open. The Grapes comprised Diamant Traube, Gros Colman, and Muscat of Alexandria. A nice lot of Apples, with some half-dozen kinds of Tomatoes, was included in this collection (silver Knightian medal). An excellent lot of fruit, Pears especially, came from Mr. Roberts, St. Saviour's, Jersey. One expects to see fine fruits from Jersey, but the Apples, except in very few cases, were not above the average. Marie Louise, Uvodale's St. Germain, Williams' Bon Chrétien, Winter Nelis, Louise Bonne of Jersey, Durondeau, and Vicar of Winkfield, under the name of Bon Cure, were very fine, the best Apples being Emperor Alexander, Warner's King, and Mère de Ménage, the dessert kinds not calling for special mention (silver Banksian medal).

A very fine collection of Plums came from Mr. Hudson, Gunnersbury House Gardens, Acton, in twelve varieties. The fruits had been grown on trees in pots under glass, and were remarkable for their splendid finish and size. Grand Duke was specially fine, as were Monarch, Coe's Golden Drop, Late Rivers, Reine Claude de Bavay, Impératrice de Milan, Ickworth Impératrice, Guthrie's Late Gage, Transparent and Late Transparent, with Rivers' Orange. In this collection were excellent fruits of Melons Eureka, Triumph, Frogmore Orange, Hero of Lockinge, Sutton's Scarlet, and a seedling (silver Banksian medal). Mr. H. Gaydt, gardener to Mrs. Gabriel, Streatham, staged a good collection of fruit, the Grapes Gros Maroc, Black Hamburg, and Alicante being well finished; a good collection of cooking Apples, with several varieties of Crabs and a few dishes of Pears completed this collec-

tion (silver Banksian medal). Mr. Miller, Ruxley Lodge Gardens, Esher, staged some excellent Peaches, Princess of Wales and Barrington being specially fine, with a nice lot of Brown Turkey Figs, good Pears and Apples, mostly kinds noted in other collections; Plums also were good, the best being Jefferson's and Kirke's (silver Banksian medal). Mr. Robinson, Elsfeld House Gardens, Hollingbourne, sent a nice lot of Grapes in variety, Melons in variety, Sea Eagle, Princess of Wales and Lord Palmerston Peaches, Dr. Jules Guyot Pear, and some Apples. With this was a collection of vegetables in twenty-four varieties, the best being Standard-bearer Celery (silver Banksian medal). From the Society's Gardens, Chiswick, were sent 100 dishes of Apples. These in most cases were well known varieties, but there were some dishes well worth notice for their distinct character. The fruits had been grown on small bush trees planted in March, 1896, and had this season suffered from drought. The new Rivers' Codlin was very good, as were Rivers' Early, Allington Pippin, and Barcelona Pearmain. The collection was given a cultural commendation. Peach Devonian came from Messrs. Veitch, Ltd., Chelsea, a new Melon from Messrs. Foot and Son, Sherborne, Dorset, but past its best, and Plum Pond's Seedling, fine fruits, from Mr. A. Ball, Cottenham, Camb.

A new Tomato called Up-to-Date was sent by Mr. J. Green, The Nurseries, Dereham, Norfolk. It is of excellent quality, but very much like Conference. A new Tomato from Mr. Roberts, Jersey, is similar to Perfection. Mr. Empson, The Gardens, Amptill House, Beds, staged a remarkably fine collection of Onions in fourteen varieties, eighteen bulbs of Record turning the scale at 4½ lbs. There was a great heap of this kind, certainly one of the best as regards shape, size, and keeping qualities. Excel-sior, Cocoa nut, Holborn, Lord Keeper, Busham Park, Ailsa Craig, Golden Globe, Red Globe, Magnum Bonum, and Brown Globe were all excellent (silver Knightian medal).

The Society's great annual show of British-grown fruit takes place at the Crystal Palace on Thursday, September 29, and the two following days. Entries should reach the R.H.S. office, 117, Victoria Street, S.W., by September 24. On each day of the show, after 10 a.m., Fellows of the Society (on producing their tickets) are admitted to the Palace free.

NOTES OF THE WEEK.

Hydrangea paniculata grandiflora is one of the best of deciduous-flowering shrubs this year, and this in spite of the great heat. In such cases, however, well-established examples will fare better than newly-made plantations. Any such instances of success are worth recording, to act as a guide in future work.

Plumbago Larpentæ.—This pretty perennial is now flowering freely, and forms quite an exceptional bit of colour in the garden. The dwarf, tufted character of the plant, spreading as it does quite freely, is not sufficiently rampant to over-run other things, and in flower is among the best bits of blue of the early autumn.

Tufted Pansies from Chirnside.—I sent you by yesterday's post some blooms of Tufted Pansies, but by mistake omitted to send the names or from whom sent. The white variety is named Pearl Jean, and has for the first season been a profuse bloomer and the habit of the plant very dwarf. The colour is a very pretty shade of white, the shape and size of blooms being extra good.—C. STUART.

Cyclamen hederifolium vars.—At the Drill Hall on Tuesday the type, as also the white form, were well represented. Even without their leaves they are singularly beautiful. It is surprising how well these succeed in permanent positions, and not a few corners in the rock garden or hardy fernery may be made more beautiful by their presence in early autumn. In the exhibit in question there would

be at least 200 or 300 of the flowers fully open, sufficient to form a good idea of the effect of such things in the garden.

Potentilla nepalensis.—Though one of the most striking of the species in respect to colour, and therefore one of the most ornamental, there is ever the drawback apparent of its rather straggling habit of growth. A form that could combine a more compact habit would be equally good for many reasons, and for the rock garden more satisfactory. This may, indeed, be readily achieved by raising a few seedlings of the plant and making selections. The species is a very profuse bloomer, but does not produce a big display at any one season.

Sedum maximum purpureum.—When seen in a good sized clump there is a distinctness about this plant that, rightly employed, renders it effective in the garden. This is due to the colouring of the leaves, which has given rise to the varietal name above. In habit of growth the plant is 2 feet high or thereabouts, and flowers during the early autumn months. The foliage is ample, and even as an isolated example the plant is quite attractive in the rock garden.

Tufted Pansies and the drought.—These have in some places suffered very severely this year—autumn-planted ones perhaps the most. In the cooler north the loss is not felt in the same degree, these plants thriving best in the north and west, where there is a heavier rainfall. Mr. Sydenham, writing us from Tamworth on the 16th, says: "I find where they are left too severely alone in warm summers they soon get mildewed. My lawn beds look worse than I ever saw them. The plants are quite dried up, and look, as you say, as if scorched with fire."

Lobelia Gerardi.—A small circular bed of this kind may be seen in the grass at Kew, alongside one of the chief walks to the main entrance by the green. The plant does not appeal to one as particularly distinct or pleasing in its tone of colour, and appears very much like what has been raised freely and oft in the seedlings from *L. siphilitica*. It belongs to the herbaceous section of these plants, all of which have had a most trying time this year, for unless the root fibres were in touch of moisture, failure more or less was almost a certainty.

Androsace lanuginosa.—Few alpinæ are more generally charming than this one, and few have borne with such impunity the great and trying heat of the passing year, and still this excellent plant flowers with unceasing profusion, and after making gay its immediate surroundings for weeks in succession still promises its pretty heads of bloom for some time to come. These are the plants that are more than welcome in the rock garden, and being of good habit and perfectly hardy withal should be always prominent in any good collection. Moreover, the plant is easily cultivated and readily increased.

Spanish Broom.—Nowhere have I seen this Broom (*Spartium junceum*) growing and blossoming so freely as in the sandy soil around Cromer. Quite close to the sea it appears to be at home, growing vigorously and producing its deep yellow fragrant flowers abundantly from July until September. Planted in masses, such clumps present a gorgeous sight when in full bloom, and as yellow flowers in the shrubberies are somewhat scarce at this season of the year, this shrub is all the more desirable. The flowers are produced in terminal racemes, and are useful for cutting.—E. M.

Lilium rubellum.—Your July 2 number just to hand. I see amongst "Notes of the Week" an article, by Mr. E. M. Webb, Nottingham, in reference to *Lilium rubellum*. It may interest your readers to know that this lovely Lily comes from Northern Nippon, where the winters are very severe, and there is no doubt that it will prove hardy in England. It is the only variety of Japan Lily which flowers in spring. Its bulbs are the first to ripen of all the varieties, therefore we can export in July-August with *Lilium longiflorum*. Another very valuable characteristic is that *L. rubellum* can be forced like *L. longiflorum*,

and will prove therefore a good Easter plant.—A. UNGER, *Yokohama*.

Rudbeckia tomentosa.—The hay-scented Coneflower is deserving of a place in the garden, and is apt to be overlooked in purchasing a selection of the numerous autumn-flowering yellow composites. Its distinct-looking foliage, greyish in colour and rather rough to the touch, looks pleasing along with the bright yellow flowers, with their dark—almost black—flattened central cone. *R. tomentosa* is not so much injured by drought as *R. speciosa*, but this year it has had to be watered several times, its drooping leaves showing its need of a supply of moisture. The flowers have an odour like that of new-mown hay.—S. ARNOTT.

Ceanothus Gloire de Versailles.—At the present time this variety of *C. azureus* is flowering magnificently against the southern front of the mansion at Melton Constable. The plants are each about 12 feet high, and in some cases they are growing along with *Ampelopsis Veitchii*, the deep green and, in some instances, bronzy-tinted leaves of the latter making an excellent background for the pale blue blossoms of the *Ceanothus*. The plants of *Ceanothus* are closely spur-pruned yearly, which preserves a neat appearance, and from the rod-like stems numerous vigorous shoots are yearly pushed and which flower abundantly.—E. M.

— On the garden front of Orchardton, Castle Douglas, N.B., this *Ceanothus* has been very beautiful this season. A well-established plant like that at Orchardton flowers freely, and forms a most attractive feature on a house or wall. The plummy clusters of flowers look most beautiful, and it is gratifying to see that it can be grown so well in Kirkcudbrightshire. Mr. Robinson-Douglas has been experimenting with some of the less hardy shrubs, and the results obtained have been such as to be encouraging to himself and others. This *Ceanothus* survived the winter of 1894-5, which was considered the most severe for many years.—S. ARNOTT.

Colchicum Sibthorpi.—If Bornmuller's Meadow Saffron is the largest and finest of the *Colchicums* with indistinct chequering, *Sibthorpi*'s is the finest of the chequered species in cultivation. Unlike *C. Parkinsonii* or *chionense*, it is with me a very reliable bloomer, and always comes so early as to allow of one enjoying its fine flowers for some time before frost comes. The blooms are very effective on account of their large size and conspicuous markings. On the grass or carpeted by dwarf plants *C. Sibthorpi* has a fine effect. Of vigorous growth, I find it come well through such plants as some of the *Acanas*, and it looks well at the base of the rock garden.—S. ARNOTT, *Carse-thorn, by Dumfries, N.B.*

Senecio candidans, from the Falkland Islands, known there as the Sand Cabbage, is a very striking plant. Its flowers are insignificant. Its leaves are, however, quite out of the way for a Groundsel. They are large, entire, and leathery. The upper surface is dark green, powdered with white; the lower surface thickly coated with a white tomentum, which is so pure as almost to deserve the epithet brilliant. As the leaves are held in a measure upright, this showy under surface is a very conspicuous thing anywhere in the garden. My plants were raised from seed sown out of doors, and have stood out for two winters, so it is presumably hardy.—ARTHUR K. BULLEY, *West Kirby*.

Lathyrus grandiflorus albus?—Like your correspondent "H. E. W." (p. 232), I have been in doubt about the name of the new white Pea shown at the recent meeting of the Royal Horticultural Society. A white variety of *L. grandiflorus* would be an acquisition indeed, but after carefully comparing the descriptions in several of the gardening papers, I came to the conclusion that the Pea was probably *L. latifolius albus* improved. I have information of a very fine variety of *L. latifolius albus* which is in the possession of a leading firm of nurserymen, and which will probably be sent out when sufficient stock is at

command. May I suggest giving Mr. Green's Pea another name than *grandiflorus*, which is hardly in accordance with present practice.—S. ARNOTT.

Kniphofia Uvaria.—Mention of the free-flowering properties of this plant is made in THE GARDEN (p. 232), a plant producing as many as seventeen of its flower-spikes. This, however, is by no means a specially large number for this kind. It is no uncommon thing for this handsome kind to produce double and even treble the number from large clumps; indeed, I have more than once had forty spikes to a plant, to say nothing of the successional spikes which had to follow. One of the greatest displays, however, I have ever seen of this fine Torch Lily was, I believe, in the Oxford Botanic Garden, where every specimen was a giant of its kind and loaded with its brilliant spikes. The same kind was ever a feature for years together in the nursery of the late Mr. R. Parker at Tooting, where great masses flowered abundantly.

Notes from a Cornish garden.—The long drought having broken up, the herbaceous plants are already looking much fresher. Here the Poppy-worts have been especially good, notably *Romneya Coulteri*, *Hummelmannia fumarifolia* and *Eomecon chionanthus*. *Gerbera Jamesoni* has been flowering on and off for the last three months, and its blooms now seem at their best. *Plumbago Larpenae* growing side by side with *Malva lateritia* is a mass of bloom. *Tournefortia heliotropoides* and *Asteriscus maritimus* are well out on the rockery, also *Linaria alpina* and the magenta *Mesembryanthemum*, which wintered out. *Crinum Powellii* is flowering under a south wall, and a patch of *Zephyranthes candida* in the same position has shown flowers for a month. *Phygelius capensis* has benefited by division. *Primula Poissonii*, *P. imperialis* and *P. japonica* lasted longer in flower than usual in a shady nook. *Hypericum Moserianum* is an acquisition. *Incarvillea Delavayi* and *I. Olga* grow side by side in the warmest spot in the garden. *Zauschneria californica* increases with great rapidity here, but this year it has no flowers, and will have to make room for something less uncertain. *Tupa Feuillei* and *T. galicifolia* seem all the better for the heat. *Anemone Whirlwind* and *A. Lady Ardilaun* are this season very conspicuous. *Physalis Franchetti* has already begun to ripen its fruits. *Cyananthus lobatus* seems to last unusually long in flower in the shade. Most of the *Asters* are at their best now. Last year's seedling *Pentstemons* are in flower still.—C. R., *Burnjoose, Perranwell, Cornwall*.

The weather in West Herts.—Another very warm week, and the third in succession. The hottest day was the 17th, when the shade temperature rose to 88°, which is higher than any similar reading registered during the summer months this year, and only 2° less warm than the maximum reading on the 8th inst. Two days later (the 19th) the highest temperature was only 62°, while the exposed thermometer fell during the previous night 2° below the freezing point, so that the changes in temperature during the week were considerable. This is also shown by the temperatures below ground, which on the 17th at 2 feet and 1 foot deep were respectively 7° and 10° above the September average, whereas at the present time the difference from that average at both depths is less than 5°. On the 16th and 17th the atmosphere was singularly dry, the difference at 3 o'clock in the afternoon between the readings of an ordinary thermometer and one with its bulb kept constantly moist amounting to as much as 19°. Rain fell for a short time on the 18th and 19th, but on neither occasion was the quantity deposited sufficient to do more than lay the dust. The ground still remains extremely dry; indeed, no rain-water at all has come through either percolation gauge for three weeks. On the four days ending the 17th the sun shone on an average for over nine hours a day, or double the September average.—E. M., *Berkhamsted*.

BURNING GARDEN RUBBISH.

WILL some reader of THE GARDEN help me over a difficulty which I have often tried to overcome? I have about twenty tons of old garden refuse and wish to burn it up. It is composed of sweepings, weeds, sticks, old vegetables, &c., but cannot get a fire to burn. I wish to know the best way to start such a fire, and how to keep it going until my heap of rubbish is all burnt up.—P. B. C. B.

* * If the weather during the last few weeks has been the same in Yorkshire as in the south of England, little or no difficulty ought to have been experienced in burning any amount of rubbish or garden refuse generally. If the heap has been long in accumulating and the greater part of it is in a half-rotten state, then it may be questionable policy to burn it. Decayed garden refuse mixed with lime, or without the latter, is an excellent substitute for solid manure, and for fourteen years in succession was the only form of fertiliser used by me on a large plot of ground that could not well be devoted to any crops other than Potatoes owing to a plague of rabbits. The results were invariably satisfactory, the last crop of Potatoes lifted turning out equal to twelve tons per acre. I made a point of having the accumulations kept well squared up together, and each autumn the mass was turned. All sticks, stones, or other rubbish that would not decay in a few months were forked out, all that would burn being eventually formed into a slow fire. About every third year caustic lime was applied to the heap of decaying refuse at the rate of one cart-load or ton to five loads of the refuse, and after this had been slaked by means of a covering of soil, the lime and refuse were well mixed together, ready for carting on to the ground in frosty weather. Lime, in addition to hastening the decay of refuse and destroying insects and disease germs, naturally added considerably to the manual value of the heap generally. It ought, perhaps, to be added that neither weeds, insects, nor diseases were more prevalent when lime was employed than they were when none was used.

After giving this alternative to burning, I will next advise "P. B. C. B." how to proceed in the event of his adhering to the resolution to burn his heap of rubbish. Previous failures are most probably due to starting with a feeble fire and smothering this before it could bear the pressure. The start ought to be made with a good heap of old Pea stakes or two faggots of light firewood, piling these in a conical shape over some straw or dry Pea haulm. This alone is not sufficient, but at least two faggots of heavy wood or its equivalent in other moderately heavy wood should be arranged on the lighter wood before lighting the fire. Directly the light wood has caught alight, enclose the heap—always conical—with some of the more woody, lighter rubbish so as to prevent the fire breaking through and burning out rapidly. On this may be placed a thin layer of moister material, adding more wherever the fire breaks through, but never a heavy weight at one time. During the first day or two, and especially while the wood lasts, the most attention has to be paid to the fire, and later on an occasional stir up is needed. Curiously enough, I am writing this in a room overlooking a slow fire which I had lit nearly a month ago, and it will be kept burning another week or more. Every evening a fresh covering of garden refuse is put on, and in the morning, wherever it is burned through, more is added. In this way a great heap of refuse of various kinds is gradually reduced to ashes, and in its place I shall have a smaller, and for my purpose, more valuable mound of "burn-bake" or charred soil, charcoal and wood ashes. This material is a sure improver of soils; the roots of all kinds of fruits, flowers and vegetables revel in it, the plants deriving much benefit from its presence in the soil.—W. I.

Names of plants.—*J. H.*—*Impatiens glandulifera*.—*J. Turner*.—*Cytisus Laburnum*.—*A. D. B.*—*Polygonum cuspidatum*.—*H. S.*—1, *Hypericum calycinum*; 2, *Polygonum cuspidatum*.—*A. E. Lowe*.—Probably *Quercus heterophylla*.

CHRYSANTHEMUMS.

NOTES ON CHRYSANTHEMUMS.

THE hot weather during the last six weeks in this neighbourhood has been all in favour of the Chrysanthemums. Many of the buds would have been very late, but now all the best varieties here are quite up-to-date, a few early crowns that were taken the first week in August being much too early. A good deal of feeding has been necessary, and later in the season than usual, for the wet weather in the early stages and the subsequent large amount of water needed have swilled a lot of the nutriment out of the compost. Some of the plants that took on a bad colour earlier in the season are feeling the effects of the hot sun badly, the weakened foliage apparently not being able to stand it. A few I stood on one side by way of experiment and shaded lightly have improved a little, and had they been taken in hand earlier would, I think, have been better still. The midribs of the leaves and some of the larger reticulations are deepening in colour, and the buds are swelling rapidly. Edith Tabor has this year gone higher than ever, and this is apparently the worst fault of this lovely variety. The buds look well and the plants are leafy right down to the pots, in strong contrast to those on Mme. Carnot, one of the worst sufferers here from leaf-rust. The well-known old W. H. Lincoln is in grand form this season, the buds having that strong, robust look, and the foliage the deep green tint and leathery texture that are the sure precursors of fine deep flowers. I have the greatest faith in soot water for syringing the plants with at this time of year, and I know of nothing that so well keeps up the vigour of the foliage in a trying time. Dry soot thrown lightly over the plants after a shower is helpful, but care must be exercised in its use. I have never known mildew to make any advance where this material has been freely used, but it must be at least twelve months old, as new soot will kill the

leaves. Three years ago I took some soot from some old greenhouse flues that were being pulled down, and as these had not been used for many years thought it quite safe to use. But the fumes from an adjacent boiler had leaked into the flues, and every plant the soot reached was more or less injured.

After the middle of September there is no telling how soon frost may set in, and some means of protection should be kept at hand. Here I use sheets of newspaper, placing them on the tops of the stakes, and these are sufficient protection as a rule from the earlier frosts. Where necessary a few small stakes should be placed about the heads of the plants to prevent any possibility of injury to the buds in taking the papers off. Any of the earlier plants that have buds forward enough to show the colour of the petals should be taken under glass, as the heavy dews and occasional showers will lead to the flowers damping. As the time for housing is not far distant, everything should be got in readiness for their reception as far as possible. The majority of gardeners have not the command of sufficient house room for all the plants without using vineries and other fruit houses. Where they have to go into the former, the Vines as soon as possible should have the laterals shortened, as there will be less foliage then to fall among the Chrysanthemums, and these obtain more light. Housing should be done while the foliage is perfectly dry, on fine days if possible. A bad attack of mildew often follows the housing of the plants in dull, wet weather. But none the less the plants like atmospheric moisture when they are inside, and until the first of the flowers open this should be maintained by lightly syringing the plants when the weather is bright and damping the floors a little. A dry atmosphere is necessary afterwards, but it must be brought about gradually, or the plants will feel the sudden change.

SUFFOLK.

Chrysanthemum Mme. L. Ligneau is another welcome addition to the early-flowering

Japanese sorts. The plant is wonderfully dwarf and compact, and although as represented by Mr. Wells in a disbudded state its usefulness was not very clear, bunches of the same variety, in which a more natural and free-flowing method of culture had been adopted, showed the beauty of the blossoms and partially opened buds. It is another proof of the adaptability of the early sorts to a natural system of culture. The colour is a pleasing shade of clear yellow, reminding one of the later-flowering Phœbus, and the florets are of good width and substance.—D. B. C.

Chrysanthemum Lady Fitzwygram.—What was stated in your last issue with reference to this variety I fully agree with, and feel sure that many growers have discarded the plant because they do not understand how to treat it to see the flowers at their best. The plants of this variety, when first submitted to the floral committee of the Royal Horticultural Society a few years ago, were dwarf and compact, each plant carrying about a dozen blossoms. Treated in this way, the flowers are useful for cutting, while if grown without disbudding the result is somewhat disappointing, and I would prefer freely-flowered plants of the old Mme. C. Desgrange.—C. A. H.

Chrysanthemum Henri Yvon.—This is the second sport from M. G. Grunerwald which has been freely shown this season. At the late show of the National Chrysanthemum Society, Messrs. H. Cannell and Sons staged a capital bunch of freely-grown flowers, though less pretty than those exhibited by Mr. Wells at the Drill Hall last week. A fortnight's difference in the time of showing is evidently sufficient to account for a considerable variation in the colour of the blossoms. The colour is a lovely cerise-pink on a pale yellow ground. The flowers are freely produced on dwarf plants. When grown in the outdoor garden these early Japanese kinds are seen at their best. When grown in pots and placed under glass the flowers have a very washy look.—D. B. C.

Forthcoming continental Chrysanthemum shows.—The journals of the various continental Chrysanthemum societies announce already a goodly number of exhibitions of the flower to be held during the forthcoming season.

Belgium, Switzerland, Italy, Germany, and France are each making efforts to hold important gatherings. The Paris show will no doubt be the most extensive, although the congress and show at Lille, organised by the Northern French Chrysanthemum Society, will undoubtedly be a formidable rival, partaking as it will largely of an international character. The congress at Troyes is another event of importance, and this will be held under the auspices of the French National Chrysanthemum Society. English growers are invited to exhibit at several, and in view of the wider interest that is being taken in the flower it is to be hoped that some of our best growers will avail themselves of the opportunity afforded. Money prizes are not often awarded, the recompenses being a rule medals of the societies holding the shows.—C. H. P.

Chrysanthemums at Fawkham.—Mr. Waterer's collection is in fine condition. As a whole the buds are swelling finely and the plants are the picture of health. Coarseness is nowhere to be seen. Nice medium-sized wood, well ripened, with leathery foliage, convinces one that careful attention to detail has throughout the growing season been observed. There are exceptions in the collection and in plants which can ill be spared, and kinds such as Mrs. H. Weeks and a few others are very unlikely to develop their blooms in time for the shows. The most promising plants were Matthew Hodgson (one of the brightest Japanese flowers), Mrs. W. Mease (the sulphur Mme. Carnot), Mary Molyneux (very tall), Hairy Wonder, Yellow Mme. Carnot, as well as the parent plant Mme. Carnot, George Seward, John Neville, Joseph Brookes, Chas. E. Wilkins, Ella Curtis, Mrs. G. Carpenter, Australie, C. W. Richardson, Julia Scaramanga, and the members of the Viviani Morel family. Every Chrysanthemum enthusiast will remember the handsome vase of Mlle. Marie Hoste set up by this grower in 1896 at the National Chrysanthemum show, and which secured the American gold medal. If this method of exhibiting the large blooms were more liberally provided for, Chrysanthemum shows would be far more popular and the practical value of large individual flowers illustrated.—C. A. H.

RUST ON CHRYSANTHEMUMS.

IN the notes by "H. S." last week he states that he has not yet heard much of the Chrysanthemum rust, although the fear is expressed that with dull, showery weather it will spread. Within the last few weeks I have received from different parts of the country portions of shoots of Chrysanthemums very badly affected with this latest disease, showing that the evil is spreading very considerably. Within the past fortnight a grand lot of plants in a well-known grower's garden has suddenly developed this very serious evil. Of some 300 to 400 plants in the collection, more than 100 are affected with the rust, and, knowing that the foliage is being subjected to a certain treatment, it will be advantageous to chronicle whether the means taken to prevent the disease spreading has been effectual. That this matter is of great importance to many gardeners most people will readily admit, and to stamp out the disease effectually special pains should be taken, by burning plants badly affected, or at least the foliage belonging to them, also isolating those less severely attacked. This also brings home to the grower the need, when acquiring new stock, of being assured that the cuttings and plants are absolutely free from any taint of the kind described above. Exceptional measures should be adopted to eradicate the evil before its ravages have become general. It would be interesting, and at the same time an immense advantage, if growers whose plants have been affected would give readers of THE GARDEN the benefit of their advice and experience in attempting to check the advance of this disease.—D. B. CRANE.

P.S.—Since writing the above note Mr. P. Waterer has raised the question of leaf rust before

the executive committee of the National Chrysanthemum Society, and that body evidently sees the importance of immediate action, and has already arranged for a conference on the subject. The conference is to take place on Tuesday, October 11, the first day of the October show, at an hour in the evening to be announced later, when it is hoped to have the benefit of advice and the professional help of a specialist in fungoid diseases.

—Will you kindly tell me in the next issue of THE GARDEN the cause of the disease in the enclosed leaves, also if there is any cure for same?—D. D.

. The cause of the disease now known as the Chrysanthemum rust is uncertain. A theory of not a few is that manures, especially those of a concentrated form manufactured from fish substances, have something to do with it. Another theory is that it is of American origin, because the variety Niveum was the first one on which the rust-like spots were noticed. We are not prepared to say which is right, but fear it is a trouble likely to be pretty general where Chrysanthemums are grown. In your case, judging from the leaves sent, the disease has got a sure footing among your plants. Probably it was allowed to do so in the earlier stages of the plants' growth before you became aware of its existence. When the plants are young it is not a difficult matter to get rid of it by picking off affected leaves. Later, however, on account of the remarkable rapidity of its spread by wind and such causes, it is not so easy to master. Sulphide of potassium has been recommended, but a recent letter from one similarly placed to yourself states without effect, and Condy's fluid had no better results. It seems to us that a mixture in which paraffin formed a part would meet the case, and quote from an article which appeared in THE GARDEN of March 26 of present year. "Take half a pound of whale-oil soap (ordinary soft soap, we presume) and boil in one gallon of water. When dissolved and boiling, add one gallon of best petroleum oil and 2 oz. of carbonate of ammonia. Stir so that all is thoroughly mixed. This forms a composition like gruel. Use it at the rate of one part to fifteen of water, and syringe the leaves, taking care to keep it well stirred the whole time." The writer states that the above mixture was absolutely effective, and for that reason it appears to us the best cure yet obtainable for a troublesome Chrysanthemum complaint.

NOTES AND QUESTIONS.

Chrysanthemum Doris Peto.—This, a pretty little pure white Japanese flower with rather broad florets, promises to make an ideal sort for outdoor culture, also succeeding well when grown in pots. The habit is dwarf and bushy, producing its blossoms quite freely and rarely exceeding 2 feet in height. This is an English-raised seedling.—C. A. H.

Chrysanthemum Albert Rose.—This is also an English seedling and is now flowering freely. As a pot plant it is useful, but succeeds far better planted out in the open border. It is a welcome addition to the early Japanese sorts, with reflexed florets, and in colour somewhat resembles a well-coloured blossom of Etoile de Lyon—a distinct shade of rose. Its height is 2½ feet.—C. A. H.

Early-flowering Chrysanthemums in France.—Some little interest is now being displayed in varieties of the early section by the French growers. The floral committee of the Paris Chrysanthemum section will hold meetings on September 8 and 22, and a show will be held on October 13 with the view of showing to the public the various kinds which are over by the time the ordinary November show is held.—C. H. P.

Chrysanthemum W. H. Lincoln.—There is evidence that this variety still finds much favour. Probably this is accounted for by reason of its accommodating qualities. Already this season quite a number of its blossoms have found their way into the market, and as they develop equally well on either early or late buds, growers doubtless prefer this variety to many other promising, but less certain kinds. A table decoration at the Royal Aquarium recently

gained its chief beauty by the use of blossoms of this rich yellow variety.—D. B. C.

Chrysanthemum Mytchett White.—This early-flowering variety, which created so much interest last season, has been little heard of so far since. Growers for market, as well as others having a demand for white flowers in the early autumn, apparently recognised the value of its chaste white blossoms, as the demand for plants right through and until the spring was well advanced was quite phenomenal. The result of this has evidently taxed the vigour of the plant, and to procure good healthy stock for another season's work, careful nursing will be necessary. In the open last year it was one of the best.—W. H.

Chrysanthemum Soleil d'Octobre.—Among the many handsome Japanese varieties introduced in recent years this is deserving of a high position. It is one of the most accommodating, and appears to succeed well from almost any bud. In October and November last year many very fine blooms were seen, and in the first week of the present month, on plants which were stopped and on others which made a natural break and first crown buds secured, flowers of high quality were developing quite freely. Cuttings inserted in the spring and finally shifted into 6-inch pots and flowered on single stems are also doing very well. At the recent show of the National Chrysanthemum Society at the Royal Aquarium in the leading group there were many excellent blooms of this lovely canary-yellow flower.—D. B. C.

ORCHARD AND FRUIT GARDEN.

KEEPING GRAPES.

GIVEN a dry, frost-proof room, Grapes, with their stems in bottles of water, may be kept for many months in thoroughly good condition with far less trouble than is usually thought necessary. The exigencies of space make it imperative for me to cut all late Grapes by the end of September, and if they are by that time well ripened I find no difficulty in having Muscats, Alicante, Gros Maroc and other such keeping varieties, fresh and plump, both in berry and in stem, until the following March. To have them in this condition it is very necessary to be chary in the use of any artificial heat for the purpose of drying the atmosphere of the Grape room, as very little of this will cause shrivelling. As a matter of fact I used no heat at all during the past winter, and never had the Grapes keep better than they did then. Previous to cutting the bunches, the bottles are filled with fresh spring water and placed in the racks, after which the room is thoroughly ventilated and dried by the aid of a gas-stove. The Grapes are then cut and taken to the room, which stands at some distance from the vinery, on the first opportunity when the outside air is dry and warm. These conditions of weather I have proved by experience to be essential. It is immaterial which end of the lateral bearing the bunch is placed in the water, and this is an important point to remember, for it gives an opportunity of leaving a few of the lower leaves and some inches of the lateral on the Vine in cases where the foliage has not yet ripened off. I do not sear the cut ends of the laterals, nor use any charcoal in the water, and do not think either is at all necessary. The water is never changed, for I find that more harm than good generally follows meddling of this sort, which cannot be done without spilling more or less of the water and creating dampness in the atmosphere of the room. It may sometimes be needful to add a little water to some of the bottles where the stems are too short to go well down, but this does not often happen when one has a choice of ends for insertion. Now and then the bunches are looked over for decaying berries, but few are ever found, unless the weather has not been quite

right when the transit from vinery to Grape room has taken place.

There are advantages in being able to clear vineries of their fruit when it is ripe, even where the houses are not absolutely needed for storage of other things, as pruning and cleaning can be done at leisure before there is any need to fear the bleeding which is sure to follow pruning when Grapes are allowed to hang on the Vines till the early months of the year.

J. C. TALLACK.

Pear Clapp's Favourite.—The hot weather has had a great influence on this Pear this season, as fruits gathered from a pyramid on the Pear stock ripened some considerable time in advance of the usual period. The first sign of their having approached maturity was given by tomtits and wasps attacking the fruits in a very determined manner. This necessitated their being gathered earlier than would have been the case, but they quickly turned and became ready for use in a short time after being placed in the fruit room. Like all other early Pears, Clapp's Favourite keeps but a short time, and should be sent to table without delay once it is fit for eating. It is a fine Pear as regards size; some fruits were quite 5 inches long and prettily coloured, much in the same way as Louise Bonno. It is also a well-flavoured sort, and is very juicy and refreshing if eaten when in perfection.—A. W.

Peach Princess of Wales.—This is a fine handsome Peach, but, unfortunately, the flavour does not come up to the standard required in private gardens. Being so fine in appearance, I have tried gathering it at various times, and have left it until dead ripe upon the tree, but in no way can it be said to be good. If gathered as soon as it parts from the tree long before it is ripe enough to drop, it is acid and wants sugar, but otherwise pleasant; but if left to drop it is insipid and without the least flavour of any kind. I have trained the tree very thinly, and thinned the crop down to a very small number; the fruit is magnificent to look at, of nice shape, and prettily streaked with red. The only way it is passably good is when grown in an unheated house in a very sunny position, and each fruit brought right up to the light by passing a lath underneath and tying the foliage away. It is, perhaps, too much to expect the flavour of Noblesse in a Peach so late as Princess of Wales, but there is room for a good light-coloured variety that would in a cool house follow the outdoor crop. At present I know of nothing in the way of pale-coloured Peaches later than Belle-garde that has anything to recommend it in the way of flavour.—H.

Outdoor Peach trees.—Once again the gathering of outdoor Peaches will soon be at an end, and as soon as finished, the trees should as far as possible be put in order. This will include the cutting away of the old bearing wood, to be followed by a thinning of the current year's growth, when too many shoots—as is often the case—have been laid in. All lateral growths should be stopped, and fasten back to the wall any shoots which may need support. This, besides preventing them from being blown about and becoming broken, greatly assists in the ripening of the wood through its coming into close contact with the wall. If spider has been rampant—and it is feared that such has been the case in many places where the water supply has run short this season—a good hosing or forcible washing with clear cold water should follow, pursuing this course for a few days until these pernicious little insects are subdued. The mulching on the alleys may be removed altogether, as this has now served its purpose, the object henceforth being to get the wood as thoroughly ripened as possible. Should the border be dry, afford it sufficient water to moisten the soil throughout and no more. Do not flood it, as this will have an opposite and undesirable effect by causing the trees to make late growth. By attending to

these few simple details at once the trees will be greatly benefited, as the wood will have a better opportunity of becoming thoroughly ripened, which in turn will render the chances of obtaining a crop another season the more certain.—S. E. P.

Peach Violette Hative.—I quite agree with all that your correspondent has to say in praise of this Peach on p. 227, as I am a grower of it both under glass and outdoors. For the latter purpose it is a most reliable sort, as it fails to bear only in very untoward seasons. It is also a very hardy variety. It bears small flowers, and the tree invariably makes an abundance of good wood, which ripens without the slightest aid beyond that usually afforded by the cutting away of the old bearing wood as soon as the crop is gathered. I have gathered some fine fruits of it this season from a west wall, and the colour, as may be imagined when the hot weather is taken into consideration, was superb; the flesh is generally stained with red, more or less, right through to the stone, and the flavour is very delicious. Under glass it is quite as good as regards flavour, and here there is a gain in size, many of the fruits this season being extra large. I lifted the tree which bore these fruits from an outside wall a few years ago to replace one which had died indoors, and have never regretted doing so, as it has always given such very satisfactory results. I am often asked to give a list of Peach trees suitable for outdoor culture, and Violette Hative is invariably included, so excellent is it in every respect.—A. W.

PEAR MARIE LOUISE FAILING.

I HAVE a large Marie Louise Pear tree about 25 feet high, with a stem 6 inches in diameter. It is trained against an east wall. It has plenty of foliage, but little fruit. Kindly inform me whether root-pruning would be of use, and, if so, at what distance from the tree the trench ought to be dug.—IRIS.

* * The fruit of Pear Marie Louise at its best is surpassed in quality by that of no other variety. The trees under favourable conditions attain to a great size, as witnessed by the above note, and grand crops are frequently obtained. Unfortunately, the variety has one serious defect—the flowers are comparatively feeble and particularly liable to injury from frosts or frosty winds. About the worst site for the tree is an east wall, and the best either a west or south-west aspect. When the trees face the east the sun reaches them quite early in the morning, with the result that frozen flowers thaw rapidly and are injured beyond recovery accordingly. "Iris" affords no information as to whether the tree of Marie Louise flowers freely or not, only stating it has plenty of foliage and but little fruit. It is not often that such large, freely-grown trees require root-pruning with a view to checking exuberance of wood growth and promoting the formation of fruit-buds, but I have known opening a trench at a good distance from the stem, saving, pruning, and relaying the roots in a fresh, moderately rich compost to cause large trees to produce a better stamp of flowers and a heavy crop of much finer fruit than formerly. It is just possible "Iris's" fine tree would be benefited by this treatment. In any case I should advise acting cautiously, as over-zealous root-pruning is liable to give large old trees a severe check, from which they are slow in recovering, if ever they do. Root-prune one side only this autumn (late in September or early in October), and complete the half-circle either next season, or, if the tree shows signs of having been much weakened by the process, defer the completion yet another year. Open the trench in front of the tree at fully 6 feet, or a greater distance rather than less away from the stem, 18 inches to 2 feet wide and as much in depth, and extend this to the wall either on the right or left of the stem. The operator should always have the tree on his left or right, as the case may be, with the aim of saving as many roots as possible. From the

trench gradually undermine the tree, using a fork for clearing the soil from the roots till it is possible to reach any strong, deep running roots there may be immediately under the centre of the tree, cleanly cutting through all of this description found. This can be done by undermining or without actually moving all the soil right up to the stem. All the preserved roots should next be examined, shortening those much bruised to a sound portion and cutting over all with broken ends to facilitate healing. Refill the trench with fresh soil, that thrown out being long since exhausted of the elements most needed by fruit trees. If fresh loam, fibrous or otherwise, is not available, use the top spit of garden soil, enriching and improving either this or loam by the addition of nearly fresh horse manure, "burn-bake," or the residue from a slow fire, mortar rubbish, and a liberal sprinkling or, say, one-quarter hundredweight of half-inch bones. These additions should form one-third of the whole mass, a moderately rich, yet not too close compost promoting the growth of strong, healthy root-fibres.

Relay the roots in this compost much as they set out from the underground stem, unless they happen to strike downwards more than is desirable, in which case they ought to be brought nearer to the surface. Make the soil moderately firm, and mulch both the fresh and undisturbed soil with strawy manure. A heavy watering is desirable if either the new soil or the old is on the dry side when moved, and if the severe root-pruning causes the leaves to flag, syringe the trees repeatedly on dry days. This partial lifting of roots should always be done before the leaves have fallen or are on the point of falling, as then the wounds heal, and either callus preparatory to forming root-fibres in the spring or actually do form them in the autumn to the no small advantage of the tree.

If after making inquiries "Iris" finds that the tree usually flowers freely, but suffers from frosts or cold winds, root-pruning had better be deferred till it is seen what can be done without resorting to this drastic remedy. All the clear space in front of the tree, or say to a distance of 12 feet from the stem, should have a surface loosening with a fork, and during the winter receive one or more heavy soakings of liquid manure, such as drainings from horse stables, piggeries and farm-yards, applied moderately strong. This would have a strengthening effect on the bloom and improve the size of any fruit that might set. Such a fine tree would pay well for protecting with blinds when in flower.—W. J.

Apple Allington Pippin.—Last year this Apple was so good that I planted some small bush trees. In spite of one of the driest seasons we ever experienced, the trees are bearing freely and the fruits even now are well coloured. This may be termed a midseason Apple, its season being from late October to March. It is a valuable addition to the dessert Apples in season at that time. The fruits are medium-sized, very handsome, somewhat conical, with red markings on the sunny side and yellow on the reverse, the flavour resembling that of the old Golden Reinette. It fruits freely as a standard. I feel sure it will become a favourite with fruit growers on account of its flavour and keeping qualities.—S. H. B.

Blackberries.—It may not be generally known that there is more than one variety of the wild Blackberry. In one place in Essex where I was employed there grew freely on a sunny slope by the lakeside, amongst the common Bracken, a very fine variety, the fruit being as large as the largest Raspberries, the individual pips large also. The fruit was borne in great abundance and was of extra-fine flavour. There was no comparison between them and the common Blackberry found in woods and by the roadside. The fruit made splendid puddings and jam. Could this variety be procured and propagated there would be no need for the American varieties, which after all are very uncertain. The growth of the sort re-

ferred to was also stout and vigorous.—J. CRAWFORD.

Williams' Pear on the Quince stock.—At the present time I am using for the dessert Williams' Pears which have been gathered from trees worked on the Quince. These are of such first-rate quality, and considered to be so very superior to the ordinary Williams' (if I may be permitted to use the term), or those grown in the usual way on the Pear stock, that a short note thereon may be of some value to intending planters. The trees in question are bushes growing in the open garden, and, as has already been stated, they are on the Quince stock. As might be supposed, they do not grow nearly so strong as trees worked on the Pear, but they are equally, if not more, fruitful, while the fruits come much larger. The skins are also much clearer and brighter, and lack the russet appearance of the ordinary Williams' Pear. The flavour, which after all is the great desideratum, is really first rate. They also have not the tendency to go sleepy quite so soon as is the usual experience with this variety, and when ripe will keep in good condition several days. When nicely arranged, from six to nine fruits make a handsome and imposing dish for the dessert and are always much appreciated. If called upon to plant more trees of this variety for affording fruit for private use, I should most certainly give trees worked on the Quince the preference, on account of the produce of such being so superior in quality.—W. H.

GRAPES SHRIVELLING.

I SEND a bunch of Grapes, and shall be glad to know the reason why all the Grapes (Black Hamburgh) have shrivelled up on the bunch sent. Some people tell me that it is either from want of water or too much water. The Grapes have not gone so in previous years. My opinion is that at one period they have been checked.—H. B. M.

* Shrivelling of berries is just now exercising the minds of numerous Grape growers, and the cause of this occurrence is difficult to determine. In each discussion that I have taken a part various reasons were assigned for this premature shrivelling. This shrivelling of berries, and which, let me add, is altogether distinct from shanking, has taken place this season in the case of Muscat of Alexandria Grapes ripened early and under apparently the most favourable conditions, and is equally bad where the ripening is later owing to either the sites of houses being cooler or to lateness in starting the Vines. Mrs. Pince's Black Muscat invariably shrivels badly in some gardens, and it is noticeable at this early date, though why these two richly flavoured varieties should be peculiarly liable to shrivelling is a mystery to most growers. There is never much water in their berries, and it is just possible that in the chemical changes that take place during the ripening the water is parted with a little too quickly.

The more watery, less richly flavoured Grapes are least given to premature shrivelling, but most of them will do so if ripened early and allowed to hang on the Vines for a long time afterwards. We have passed through an exceptionally hot and dry summer, but during July and part of August the nights were cold and fire-heat could not be wholly dispensed with accordingly, so that the atmosphere was dry both by night as well as day. The tendency would, therefore, be towards early maturation of fruit under glass, and this is what took place in the case of the bunch sent. It was perfectly ripened, and when cut was well advanced towards the raisin stage. During hot and dry weather the foliage parts with a great weight of moisture in a few hours, and in many cases the borders both inside and outside required to be watered at least once a week. Curiously enough, many gardeners never pay much attention to outside borders, these being supposed to get all the water they require from the heavens. They may do so during a wet, sunless summer, but owing to neglecting to water and mulch outside borders numerous

crops of Grapes are in a poor plight at the present time. Some growers are afraid to water the borders after the bunches have commenced colouring, and an application of liquid manure at that late period is supposed to be highly injurious. From first to last the borders ought to be kept constantly moist, not saturated. Caught at the right time or before they become dry to the extent of crumbling when tested, a little water or liquid manure will go a long way, but wait a few days longer and three times the amount will not effect the remoistening so thoroughly and well. My borders, which are still receiving weekly supplies, are composed of sandy, clayey loam and require water oftener than do those of a more retentive nature, so that there is no fixed general rule as to when to water. Allowing the borders to become dry and then giving a heavy watering is bad practice and a frequent cause of cracking of ripening berries. Ceasing to water after the crops are ripe is bad for both the Vines and the Grapes, and if this was done in the case of the Vines producing the bunch before me, if only for a few days longer than usual, this might have been responsible for the shrivelling. Keeping the borders steadily moist need not end in ripe Grapes decaying wholesale, nor in the loss of a few berries even. Inside borders ought to be well covered with straw litter, the watering should be done in the mornings of clear days, and a good circulation of dry air, with or without the aid of fire-heat, maintained. A very light shading acts most beneficially during very hot weather, and is most desirable when there is no air space between the Vines and the glass, preventing early loss of colour in the case of black Grapes and saving the foliage.—W. I.

Nectarine Pine-apple.—This dainty variety has done grandly again this season, a young tree in the worst corner of a span-roofed house having finished up a heavy crop of fine fruit. It is later than Humboldt and of superior flavour; otherwise it resembles it with its deep yellow flesh and fine colour outside. Early Rivers, Lord Napier, Humboldt, Elruge, and Pine-apple are a fine lot in ordering of ripening. Pine-apple is not a very strong grower and will not stand rough treatment so well as some others, still it is a good kind and one that may be planted with every confidence.

Apple Duchess of Oldenburg.—In a cottage garden in Essex this week I noted one of the finest trees of this popular Apple I have seen. It was only about 3 feet high, but had evidently been well eared for, and the fruit was excellent, though there was a heavy crop. In private gardens this is getting well known as one of the best early kinds, and it seems to me to be just as useful for cottagers and small gardens generally. The flavour is brisk and the flesh is not mealy like that of some early kinds, while the fruit is handsomely striped and quite large enough for dessert. It is also a constant bearer and grows freely.—H.

Plum Gisborne's.—As a stout-growing free-fruiting cooking Plum this would be difficult to beat. It is as free-bearing as Victoria and very healthy and clean in growth. The fruit, produced very plentifully, is of medium size and bright yellow in colour, not unlike Pershore, but rather smaller. A difficulty is often found in providing fruit in sufficient variety for compotes, but these yellow Plums are always liked by good cooks and are not always too plentiful. The great advantage of this and similar hardy kinds is that they can be grown in almost any description of soil or situation, provided it is firm and open.

The Japanese Wineberry.—This is a nice-looking plant and bears fruit with the greatest freedom, but, excepting in the case of cultivators who like curiosities, it will probably never be grown to any great extent. Its principal use seems to be for preserving, and some long rows in any light, sunny part of the garden would pay for growing for this purpose. Some people like the brisk acid, juicy berries, but good fruit would,

I think, have to be very scarce before this will find a place in a good dessert. It has a striking and pretty effect, however, while growing. To get good fruit the plants should be allowed plenty of room, and as it is a gross feeder, the border must be very rich.—H. R.

Fruit trees over walks.—The late Mr. Wildsmith, of Heckfield Place, was one of the pioneers of the arching over garden paths with Pear trees trained as cordons. The examples found there some twelve to fourteen years ago were admirable and dropped abundantly. One of the most perfect examples of this form of Pear training may be seen at Sandhurst Lodge, Berks, where there are three garden paths, each about 50 yards long, covered most efficiently. The largest or loftiest arched path of this nature I have seen is at Buehan Hill, near Crawley, for that is lofty enough and broad enough to enable an omnibus to pass beneath. This one also includes Pears, Plums, and Apples, all being trained as cordons and planted close together. At Madresfield Court a broad centre walk is so planted with Pears only, but these are fully 12 feet apart on each side, as large bush trees come between. The path from tree to tree is 6 feet broad. But these trees trained up each side cordon-wise, yet have three branches carried out horizontally from each side overhead and about 2½ feet apart. These are secured to wires strained tightly to the garden walls at either end of the walk, which is some 400 feet long. In each case fruiting is liberal, but for the production of colour effects, varieties that give good coloration may well be employed. Amongst Apples, Golden Spire, Col. Vaughan, Worcester Pearmain, May Queen, and Baumann's Red Reinette may well be planted. Fertility, Durondeau, and Beurré de Capiaumont Pears are excellent. The plan is one that is productive of pleasing effects in kitchen gardens, and enables paths to be most profitably utilised.—A. D.

NOTES AND QUESTIONS.—FRUIT.

Strawberry Lady Suffield.—I think the committee of the Royal Horticultural Society were fully justified in recently giving an award of merit to the new Strawberry Lady Suffield. I have tasted it and found it one of the sweetest and richest-flavoured Strawberries I know. The fruit is of medium size, dark in colour, ripening to the point. It should become a favourite wherever flavour is appreciated.—J. C.

Apples at Madresfield Court.—Whilst there seems to be an abundant crop of Apples on all descriptions of trees at this place, especially on cordons, on wires, and old and fine espaliers, there is a long row of semi-bush trees on Crab stocks edging one side of a path, each about 16 feet in height, all carrying quite heavy crops. These trees were planted but 2 feet from the edge of the walk, and therefore have on the walk side had to be kept rather close cut. The branches in other directions do not exceed 5 feet to 6 feet.—A. D.

Mulching Strawberries with grass.—One sometimes sees Strawberry beds mulched with short grass from lawns, but the practice is a bad one for several reasons. In the first place, should rain come while the grass is fresh, it clings to any fruit that may be lying on it; and secondly, it soon decays and becomes little better than manure, the feet sinking into it and making it anything but pleasant. Grass mowings are all very well for placing round newly-planted shrubs, but as a mulch for Strawberries and fruit bushes they are most unsuitable.—C.

Rubus laciniatus.—In the course of his recent lecture on "Suburban Fruit-growing," Mr. Roupell stated that *Rubus laciniatus* was proved to be an indigenous species because it frequently came up from loam carted in from a particular common. Certainly the species has been long regarded as of American origin, and it is odd that whilst thriving so well here wherever planted, and even negligently treated, yet it never seems to be found growing absolutely wild. That it is the most profitable and early of all Blackberries there can be no doubt. Inter-crossing Blackberries and Raspberries seems so far to have resulted in simply spoiling both fruits. We can have superb Blackberries if we wish to select and grow from the best, and undoubtedly we have grand Raspberries.—A. D.

STOVE AND GREENHOUSE.

BOUGAINVILLEA GLABRA.

For growing under glass in this country, *Bougainvillea glabra* is, generally speaking, the more useful of the two species that are in cultivation, though in the tropics, where there is ample space for its development, the larger-

form far more pleasing objects than when tied into a hard and formal shape. As a roof plant or for furnishing the end of a glass structure it is one of the best plants we have, while good-sized specimens of it are turned out of doors during the summer in some of the London parks, and flower freely under this treatment. This latter circumstance should tend to explode a widespread fallacy that stove-heat is neces-

shoots were pushed through the top lights into the open air, in which position they flowered profusely, and the bracts produced were richer in colour than those under glass. The soil best suited to this *Bougainvillea* is good turfy loam, with an admixture of leaf-mould and sand. Specimens intended for clothing walls, roofs, or pillars should be planted out in preference to keeping them in pots, though the root-run

must be restricted, as in this way the plants flower much more freely than if in a large border. The flowers proper of this *Bougainvillea* are but small and not at all showy, the beauty of the inflorescence consisting of the large brightly coloured bracts which are so freely borne. When in a confined border, liberal doses of weak liquid manure during the growing season will be of great service. As soon as the flowering period is over which in a cool house will not be till autumn is fairly advanced the plants should be kept somewhat drier at the root in order to thoroughly ripen the wood. Early in the year, should space be limited, they may be closely spurred in and any exhausted wood removed. Then with the return of spring the plants will break out freely and produce their flowering shoots in great profusion. The bracts, which are of a beautiful rosy tint, vary a good deal in hue according to the conditions under which they are produced, as in a moist, shaded structure they are much less effective than where well exposed to light and air. Besides the difference in colour induced by its surroundings, there is also a variety of *B. glabra* in which the bracts are a good deal deeper in tint than those of the type, while it is so excessively floriferous that even little plants in 2½-inch pots will produce several bracts. This is the variety *Sanderiana*, met with, I believe, in an old-fashioned garden in the south of England. The fact of this variety flowering so freely in a small state has caused it to attain a considerable amount of popularity.

Bougainvillea spectabilis is altogether a larger and more rampant-growing plant than the preceding and by no means so sure in flowering. It is also more variable than the other, as individual differences exist in the production of the blossoms, in the colour of the bracts, and also in the degree of hairiness on the leaves. This *Bougainvillea*, or at all events but a slightly removed form of it, is known as *B. speciosa*, and there is a variety *lateritia* with bracts of a distinct reddish tint. Bright sunshine is absolutely necessary for the successful culture of *B. spectabilis*, as without this we get very few bracts, and even those that are produced are wanting altogether in the rich hue of those that get plenty of light and sunshine. The great beauty of this *Bougainvillea* in the cultivated regions of the tropics is proverbial, and that we cannot reproduce it here is owing principally to the less amount of sunshine that we experience. This is well shown by the fact

Bougainvillea glabra. From a photograph sent by Mr. R. Kelly, Kelly, Liffon, Devon.

growing *B. spectabilis* forms a gorgeous feature. *B. glabra*, which was introduced into this country in 1861, quickly became popular, especially for growing into specimens, which at that time were to be met with at most exhibitions. Apart from the large trained plants, which give a good deal of trouble, it may be grown as a bush, in which way it will flower freely and

sary to the successful culture of this *Bougainvillea*, for it will thrive perfectly in a warm greenhouse, or at most an intermediate structure. A large plant of this *Bougainvillea* clothing the end of a greenhouse came under my observation, and its behaviour well showed that fire-heat during the summer was by no means necessary, as numerous long flexible

that after an excessively hot summer the following year's display of bloom is generally much above the average. Conditions most favourable to it are a stove or intermediate house temperature, a large structure, so that there is no need to curtail the long rambling shoots, full exposure to light and sunshine, and a thorough rest, induced by a lessened amount of water and a somewhat lower temperature during the winter. The less pruning indulged in with this *Bougainvillea*, the greater the display of blossoms, as the bracts are borne on the previous year's shoots. A particularly fine coloured form of *B. spectabilis* is just now flowering on the roof of the Cactus house at Kew, and close by is a plant of *B. glabra Sanderiana* in the same stage. The *Bougainvillea glabra* figured herewith is, according to a note from Mr. R. Kelly, Kelly, Lifton, Devon, 18 feet wide, 16 feet high, and was planted out in a bed 5 feet 6 inches wide by 2 feet 10 inches deep. It covers part of the east end of a conservatory and part of the roof and is kept dry from October to March.

H. P.

***Acalypha hispida*.**—The splendid group of this plant from Gunnersbury House so well shown at the Drill Hall on Tuesday last affords another illustration of its value. A special point concerning it is its vigour, and the fact that a warm greenhouse satisfies the plant. When first seen it was by many regarded as of the same delicate rooting character as the *Poinsettia*, which is so liable to lose its foliage when overwatered. Any who so regarded it need not have given one glance at the mass of vigorous tree-like roots that were reaching the top of the pot in several instances. These roots alone demonstrate the plant to be one of vigorous constitution and growth generally, and so far as can be gathered by roots alone the plant will readily assimilate rich food in plenty. The majority of the plants previously exhibited have been carefully mossed over the surface soil, therefore nothing could be seen or deducted from the method of rooting. Fortunately, Mr. Hudson had no such covering, with the result that a useful, if not indeed valuable, object-lesson was at hand for all who cared to embrace it. It was not merely a root or two, but large numbers of them, more like the young roots of Fig trees, that were crowding the loam that had been employed as a top-dressing, and seeing the plants carried all their foliage to the pot was further proof of the general condition of the plants. This useful plant is said to be well-nigh perpetual in the production of its rosy crimson appendages, and further that they come in winter as freely almost as at any other time. If this be true there is a future for this plant, which the floral decorator will most readily embrace. In winter decoration it would prove invaluable.—E. J.

Balsams.—Balsams when well grown are very ornamental and most useful for the conservatory when many of the summer-blooming plants are over. As a rule they are not met with in good condition, the chief cause of this being too little heat in the early stages of growth and being kept too far from the glass, together with an insufficiency of air. To grow balsams well the seed should be sown in well-drained pans in a compost of fine loam, leaf-mould and silver sand, and placed in a temperature of at least 60°. As soon as the seedlings appear they should be placed close to the roof-glass, giving a slight shade on hot days, as the tender leaves are apt to scorch. When the second pair of leaves is formed, the plants should be carefully lifted with the aid of a plant label and potted into small pots, lowering them so that only the foliage is seen. The lowering secures sturdiness and new roots start from the stem. Balsams being gross feeders, a liberal diet must be given. A good holding loam, enriched with plenty of well-decayed manure, with abundance of sand added to ensure porosity, suits them well. Good drainage is necessary, as the plants when in full growth take

liberal supplies of water. A shift into a 4½-inch pot must be given as soon as the roots are working freely, a pot-bound condition being ruinous. As soon as weather permits a removal to greenhouse quarters will be necessary, and although draughts must be avoided, a current of fresh air will be needed to ensure sturdiness. The earliest batches may be grown on until they occupy 9-inch or 10-inch pots, while successional lots will do well in 6-inch pots. Liberal supplies of liquid manure of medium strength given in summer will help the plants much. If placed in a cool, shady house when in full flower they will last some time in good condition.—J. C.

NOTES AND QUESTIONS.—STOVE.

***Swainsonia galegifolia alba*.**—I find the best way to grow this for the supply of its pure white blossoms in quantity for cutting is to plant it out in a rather restricted root-run, giving abundance of water at the root and liberal supplies of liquid manure. Without thorough moisture at the root, red spider is almost sure to attack the foliage. For covering the back of a greenhouse wall up to 8 feet high where a fair share of light is obtained, this is one of the best of subjects.—E. M.

***Campanula Balchiniana*.**—This charming hybrid between *C. fragilis* and *C. isophylla alba*, with its free growth and charming variegated foliage, is a delightful plant to grow in pots for house decoration. The leaves, which, while differing from those of one of its parents, *C. isophylla*, yet resemble them in some particulars, are deeply bordered with white, and the variegation is persistent, retaining its effectiveness all the year. The flowers, which resemble in shape those of *C. fragilis*, are silvery blue. It does well in a gritty soil, requires some shade in hot weather, and should not be over-watered. This variegated *Campanula* deserves to be widely cultivated.—R. D.

FLOWER GARDEN.

FLOWER NOTES FROM SWITZERLAND.

THE summer months have gone, and yet summer, as though loth to die, turns back again and yet again to cast a long enchanting smile across the landscape—yet, Oh! Summer, Summer, why should you die? Yesterday, wreathed in mist, we thought that you had gone—to-day we wake to find the mountain clear as fairyland and sky celestial blue—tomorrow, perhaps, like our English swallows, you may surprise us suddenly by having left. This Sunday morn, bathing in your delicious smiles, I cannot picture that you are near your death. To my left, in dazzling light, the massive glacier fills the valley, behind is a wall of sun-heated rocks, on the right the Bristenstock rises, with its everlasting snows, and before me, across the valley, eight torrents—leaping, gliding, sliding, foaming, now pouring in unbroken streams, now cast into a thousand cataracts—pour on for ever and ever with unceasing roar. In sheltered nooks beneath protecting rocks some summer flowers are hiding still. In the deep shade of the Fir wood groups of pale yellow Foxgloves are seen, mixed with the spiked Veronica, beaked Crane's-bill, and blue Speedwell stretching to the light. Tremulous as the frail *Dryopteris* amongst which she grows, the *Campanula* shakes her bells amongst the Fern. On sunny banks the vivid green of Strawberry leaves shelters a gift of autumn fruit between the dried stems and ghostly seed-pods of past flowers. The starry heads of the Grass of Parnassus rise everywhere, and on the open sward the lovely *Achemilla* leaf, like pale green velvet shot with grey, creeps out to meet the green Whortleberry. Great bushes of giant Balsam scent the air, and the autumn Gentian makes tall masses of deep blue. On the higher Alps, where

the white goats wander with their tinkling bells, the last sprays of wild Thyme and purple Heather make the short turf sweet, and higher yet again, where marmots are heard squeaking and all undergrowth has ceased, a lovely scheme of colour charms the eye—tall Thistles, whose large silver flowers mix with heads of deep blue Aconite upon a rock-ground of tender grey. Only upon the ledges and dripping banks, beside the waterfalls in the valley, is plant growth still luxuriant and rich. Heavy heads of Valerian, with its thick juicy leaf, Monkshood, Willow Herb, and many other noble water plants dance in sun and shade, hiding amongst the magnificent fronds of damp Fern that bend beneath the constant cloud of gold-besprinkled spray. But space is too limited to describe the beauty of flowery Switzerland, even when she is wrapped in a sad September shroud. M. C. D.

Maderanerthal.

Hardy Fuchsias.—How pleasant it is to see huge clumps of these Fuchsias growing out of doors year after year without any protection. It would be difficult to find them more numerous in one locality than is the case around Cromer, in Norfolk. There they grow in almost every cottage garden, many close to the sea, and appear to revel in the sandy soil and pure air. Some exceptionally fine specimens are to be seen in Lord Battersea's garden at Overstrand, many of the clumps being 8 feet high and as much as 16 feet in diameter. These growing singly close to the paths have a fine appearance when smothered, as they were in August, with their purple blossoms. How much better an effect they would produce if they were growing on the grass independently of any other subject where their whole beauty and natural grace could be seen.—E. M.

Aster F. W. Burbidge.—This deserves a brief note. It was raised at Newry by Mr. T. Smith and sent out in 1896. One finds it difficult to describe the colour of many of the Starworts, and the variety under notice is no easier in this respect than many others. I see it catalogued as "soft rosy blue" and as "a lovely shade of rosy lilac." I think the latter description comes nearer to the colour than the former and is sufficiently close to give a good idea. The flowers are large, and even in my light soil they are as big as a half-crown, and must be considerably larger in stronger soils. This season it has grown upwards of 4½ feet high. The flowers are very freely produced, and the first opened this year about the beginning of September. Aster F. W. Burbidge appears to belong to the *Novi-Belgii* section.—S. ARNOTT.

***Acæna Buchananii*.**—About two years ago I made my first acquaintance with this charming New Zealand Bur in the rock garden at Glasnevin. What delighted me was the beautiful colouring of the foliage. From want of a better term one may call it "pea-green," although this fails to convey an idea of the prevailing hues of green which compose the colouring of the finely-divided foliage of *A. Buchananii*. This year, through the kindness of a friend, I have been fortunate enough to obtain it for my rock garden. Although of free growth, it does not appear to have the encroaching habit of some of the New Zealand Burs, and should this be one of its characteristics it will be the more valued for the choicer parts of the rock garden. At Glasnevin this year and at Carton it appears to retain this less rampant feature. I have not seen it in flower or fruit, but I anticipate that when in bloom it will lack the brilliancy of *A. microphylla*. *A. Buchananii* is grown at Kew, but does not appear to have generally found its way into commerce.—S. ARNOTT.

***Helenium autumnale superbum*.**—A tall, freely-branched, and freely-flowered example of this composite obtained the award of merit of the Royal Horticultural Society at the Drill Hall last week, and the same variety may now be seen

flowering at Kew at the end of the mixed hardy plant border hard by No. 7 greenhouse. At Kew the plant is nearly, or quite, 8 feet high, and attention is directed to it to inquire whether the adjective is here applied solely because of the increased height the plant attains. So far as the flower-heads are concerned, these are much smaller than in the plant usually sold as *H. autumnale* (type). By a singular coincidence also, the plant at Kew, scarcely normal even in the lower portions of the stem, develops into a broad, flattish, fasciated stem in the upper parts, the same thing, only considerably less in degree, being noted in the example that obtained recognition at the hands of the floral committee on the 6th of last month. Under these circumstances it would be interesting to know whether this fasciation is characteristic of the variety, as it does not usually appear in the typical species.

THE BURMESE LILY.

(*LILIUM OCHROLEUCUM*.)

A FRIEND of mine received a number of bulbs of this fine Lily two and a half years ago from his son in Burmah and gave me a few of them. They have now been over two years in the open ground, merely covered with ashes in the winter, and have flowered well. The accompanying illustration shows one now in flower. The stem is 6½ feet high and the flowers are each 6 inches long by 5 inches in diameter, but the long drought this summer and a rather poor soil have reduced their size, as some grown by my friend in pots last year were much larger. They grow on the Shan plateau about 4000 feet to 5000 feet above the sea in tall grass, which protects their stems and roots from the heat of the sun. The soil they were growing in is a deep red loam, and any fairly good loam will no doubt suit them, my soil here being too sandy and poor to grow them to perfection. If planted rather deep and protected from frost in severe winters they will probably be quite hardy in the south of England.

Parkstone, Dorset.

A. R. W.

Calandrinia Tweediei.—This species, which is a recent introduction, has been mentioned once or twice of late, but so far, I think, no note has been made of its very profuse flowering, which, happily, appears to be general. Indeed, it is so at West Kirby, in Cheshire, and also in the Royal Gardens, Kew, where a nice colony of the species exists, the flowers being freely borne on slightly forked and rather succulent stems. A similar freedom of flowering exists in my solitary example. The plant is so distinct and really first-class that one cannot but desire its complete hardiness in this country. The hot, baking sun of the year, considerably prolonged beyond that of average summers, has exactly suited this excellent subject, the individual flowers of which are the size of a half-crown piece, and therefore attractive.

Michaelmas Daisies and the dry weather.—These are not nearly so fine this season as last year. The long continued spell of dry weather has caused the plants to lose their foliage, and several varieties have flowered much earlier than usual. *Aster Shorti* came into blossom all of a rush, and was over in a few days, leaving the plants in a most miserable and impoverished condition. *A. Novi Belgii levigatus* is already over, and has never been satisfactory with me this season. *A. acris* was very short-lived. *A. cordifolius* with its soft mauve blossoms has always been an especial favourite, but at the moment looks anything but like its usual self. On the other hand, the following are coming along better, and look decidedly promising: *A. Amellus bessarabiensis*, *A. N. B.* Harpur-Crewe, *A. Coombeshacre*, and some of the later sorts.—*D. B. C.*

FLOWER GARDEN NOTES.

THE large batch of hardy perennials raised from seed in the majority of cases having attained very considerable dimensions, and likely if left longer in the nursery beds to suffer from removal, has induced me to start rather earlier than was at first intended transferring them to permanent quarters. I should have preferred lifting the whole of the plants at present in the borders, and, after hasty trenching, replanting the best of them with the new stuff on hand, but as time and labour will not admit of such a thorough renovation, I propose clearing away things hardly up to date among hardy plants, and, after a careful preparation, replacing them with the batch of

Let me note here that, whilst fully alive to the facilities for filling such borders by the aid of seedlings, cuttings, layers, or division, it should be remembered that at the first planting or replanting where first-class things are not in stock, the operation will be a little expensive. An idea seems to prevail that hardy plant borders may be filled with little or no outlay. So they may, doubtless, in a sense, but now that in the majority of species there are so many first-class things, it seems a pity not to plant of the best. Poor varieties are no credit to the planter, and are very disappointing to the owner when he comes to witness the display made. I have before suggested, where facilities for purchasing in quantity do not exist, the advisability of buying two or three in each case of really good things, planting them in well-prepared nursery beds, so that at the end of the next season a good stock may be obtained. Preference should always be given not only to good things in the way of flower, but to those that can be depended on to grow and bloom freely. Milfy subjects must be distinctly avoided on permanent borders.

CARNATIONS.—A recent editorial note that insisted on hardy varieties of free, vigorous habit was emphatically the right thing for the subject under discussion. What is the use in such positions of sorts that will only throw two or three weakly bits of grass, and perhaps only a single flower-spike? They may be all very well in isolated positions if the flower is exceptionally good, but to furnish a broad breadth of bloom they are practically useless. Sorts vary considerably in different soils and situations, and also in seasons as a rule. Hayes' Scarlet, Murillo, The Pasha, Countess of Paris, Carolus Duran, Mrs. Eric Hambro, and Miss A. Campbell are first-rate. The two last are rather straggling, with extra long flower-stems, and require naturally plenty of support, but as respectively a hardy, free-growing white and yellow they are about the best I have tried. Pink and white Cloves are grown, but the old crimson had to be discarded on account of its susceptibility to disease. It is very strange that it is so. One could understand the matter a bit if all the Cloves were attacked and the finer, less succulent grass escaped, but that the crimson planted between the white and pink should be covered with the spot and the other two perfectly clean is to me one of the mysteries of Carnation growing.

STATICE LATIFOLIA.—Reference was made last season to a batch of seedlings of this so far as variation in colour, size of individual flower and panicle, and early or late blooming were concerned. The variation is quite as pronounced this year, and I would strongly advise the raising of a batch of seedlings. They will be found exceptionally valuable for cutting.

E. BURKELL.

Hop-covered archways.—Few things have a more elegant appearance as a covering for garden archways than the common Hop. A capital temporary arch may be made over a grass or gravel walk by planting on each side a stool of

Lilium ochroleucum in a Dorsetshire garden. From a photograph sent by Mr. A. R. Wallace, Parkstone, Dorset.

seedlings. The borders were rather hurriedly filled in some years ago with almost anything that came to hand; consequently the infusion of new blood will give a better and a more varied display. The soil is naturally poor, especially in spots that have been occupied by those plants that, to use a common phrase, "take a lot out of the ground," and so I am working in plenty of cow manure, burying the same at such a depth as will admit of the roots of the newly-planted stuff getting a good hold of it. In the front rank I shall find it advisable to do away with nearly all plants already in the border, for on this light soil anything that does not get a firm, deep grip of the ground is not so good the second season.

Hop roots, then taking about eight long limp Ash rods, sharpening the stout ends, and inserting them securely into the soil, four on each side, bending them over till they meet, then tying them together, fixing a few cross pieces of wood to hold the poles in position. The Hop growth quickly covers them. The arch can be taken down for the winter as soon as the haulm dies down. Wire arches are often met with partly covered with Roses and other things. These when bare of foliage during winter are anything but ornamental even in a kitchen garden.—J. C.

Cannas.—What an admirable addition to our gardens in autumn is the new race of dwarf-flowering Cannas. Each year brings us improvements on the older varieties, and as hybridisers both at home and abroad are engaged in the attempt to make them more perfect, we are likely to be confronted with the difficulty of selecting those that are the best. The flowers are much larger, rounder in petal, and perhaps more striking in colour than they were two or three years ago. Although they may be used in filling up the gaps in borders made by the early spring bulbs, and are very effective for this purpose both from their striking foliage and bright flowers, yet unquestionably they are seen to the best advantage when planted in a bed by themselves. I think it is a mistake to put anything else in the bed so as to form a carpet for them: they stand out so well and their broad and ample foliage does not associate well with those bedding plants which are sometimes placed with them, whilst if space can be spared, it will be, of course, better to have beds of the dark-coloured varieties and others of the yellow-spotted and yellow-margined kinds; but in small gardens this can hardly be effected, and they look very well when mixed together. They are also easily kept during the winter, requiring much the same treatment as Dahlia roots, though perhaps it is better to keep them a little moist. They are also very easily propagated, so that a good stock of them can easily be acquired.—D.

The Flame Flower (*Tropaeolum speciosum*).—It is now some fourteen or fifteen years, perhaps more, since I first saw this brilliant *Nasturtium*. I had gone to the south-west of Scotland, and when I first saw it on the front of a cottage near Newton Stewart I was amazed at its brilliancy, and wondered how it was one never saw it down south. I saw it there in all directions, covering the churchyard wall of the Episcopal church close to that place. I saw it on many a white-washed cottage, whose walls threw out in great relief its brilliant flowers and bright green foliage. I saw it climbing up the front of a manse in the Trossachs, and throwing itself in wild profusion over the Apple trees in the garden of Penninghame Castle. I was told it was a perfect weed wherever it got established, and of course naturally I desired to try it myself. I have done so for many years, and yet in every instance it failed. I was very much surprised, however, to find that Mr. S. Arnott should have failed with it in such a situation as Dumfries. I was told that it required a north aspect and plenty of moisture, so I placed it in such a position, but with no good result. I found the roots running about in all directions, throwing up shoots but not flowering. I have made an effort again this year to overcome the difficulty. I received some fine roots and placed them in a basket (the bottom of which had been knocked out) in well-mixed light compost, and then plunged them in a north border close to a bush. They have made good growth, run up into the Guelder Rose just by, but as yet have shown no flower. I hope, however, that next year I may have some better success. I cannot but think that the moist climate of Scotland has a good deal to do with it. I know that it can be grown in the south of England in some places; I have seen it flourishing on the walls of Berkeley Castle, in Gloucestershire. Mr. George Paul tells me that it succeeds with him at High Beech, in Epping Forest, and Mr. Harry J. Veitch tells me it is the one thing that has not disappointed him in this droughty season at East

Burnham Park, near Slough. I have not seen much notice of it in Devonshire, but I should think the character of its climate would suit it admirably.—DELTA.

PLUMBAGO LARPENTÆ.

THIS is justly a favourite among our late autumn flowers. Of a fine shade of blue, its blooms look very attractive in a mass on rock-work, while later its foliage dies off of a very effective colour. It is, so far as I know, synonymous with *Ceratostigma plumbaginoides*, the name adopted in the Kew "Hand-List of Herbaceous Plants," although the compilers of the "Index Kewensis" have not apparently recognised this in their magnificent work. When first introduced into this country much was expected of *P. Larpentæ*, and as at that time there was a great demand for new plants it was eagerly sought after. It was said at the time that orders amounting to no less than £5000 had been booked for plants of this Leadwort in nine months. The price at first ranged from £2 5s. per plant to £3 13s. 6d., but rapidly declined, so easily was it propagated. This was in August, 1847, the *Plumbago* having been sent to Sir George Larpent in May, 1846. It was found growing out of a crevice in the city wall of Shanghai—at least, so says the "Floricultural Cabinet" for January, 1848, where a fairly good coloured plate appears from a plant belonging to Knight and Perry, King's Road, Chelsea, who owned the stock. It was exhibited by Sir George Larpent's gardener at the exhibition of the Royal Botanic Society in July, 1847, and was figured in the *Gardeners' Chronicle* for that year. Dr. Lindley is the authority for the name at the head of this note, but that of *Ceratostigma* was given by Bunge. It is to be regretted, however, that Bunge's name is so cumbersome, and in the interests of the flower itself, as well as of those who try to grow it, we are, I think, justified in adopting Dr. Lindley's in preference.

It is interesting, in view of its present position, to observe the references to *Lady Larpent's Leadwort* in the columns of the horticultural press of fifty years ago. The late Mr. D. Beaton wrote enthusiastically in its praise, apparently commending it as a greenhouse and window plant. He confidently predicted that it would soon be found in every cottage in the land. Various kinds of treatment were tried, among others that of the stove, which proved very unsuitable. Many and bitter seem to have been the disappointments experienced so far as we can judge from the correspondence in the gardening papers of the time. However interesting this retrospect may be, we are perhaps more concerned with the present and future of the plant as a hardy flower, which is its proper sphere in our British gardens. It is to be feared that many have been baffled in their attempts to bloom this Leadwort in consequence of its late-flowering habit and its disinclination to bloom in cold districts and situations. This is very unfortunate, as plants of similar character coming into flower in late autumn are none too plentiful and are highly prized. In my garden I find no difficulty in blooming it annually; but then it is grown in the hottest and driest part I have in the garden, and is besides in very light and sandy soil, made poorer still by reason of the roots of a hedge which is behind. At times, in prolonged drought, *P. Larpentæ* appears to suffer, and may require occasional watering in such a position as that referred to. The principal consideration—plenty of bloom—is, however, obtained, and when the flowers are over the tinted leaves are very beautiful. Such is the treatment I should

recommend to those who cannot flower it. Given a high, dry, and sunny position in light soil, there is, I think, little fear of success, except in districts having exceptionally cool summers. Another method is suggested by the place in which *Plumbago Larpentæ* is said to have been found, and that is to grow it as a wall plant. The difficulties of establishing it once overcome, and a summer or two being over, it ought to be a success on a sunny wall, where its deep blue flowers would look very effective. I venture, therefore, to plead with those who have suitable positions in their gardens on behalf of this beautiful dwarf plant, too seldom seen now, but wherever seen much admired. S. ARNOTT.

Carsehorn, by Dumfries, N.B.

Phygelius capensis.—It is quite possible that this beautiful and striking plant, to which Mr. Arnott directs attention at p. 219, will be more generally hardy on the wall as referred to, and of course much less vigorous in habit. I do not think, however, the full worth of this beautiful plant will be forthcoming in such a place. At the same time it is interesting to know of its success so placed, and I take it also to be quite hardy on the wall at Glasnevin, which is not always the case in the rock garden or border.—E. J.

Salvia patens alba.—I think I saw this somewhat rare plant for the first time when in St. James's Gardens, West Malvern, recently. It is a pure white reproduction of the well-known *Salvia patens*, which is there grown in great quantity. How very rich in unison are these fine deep blues with the intense scarlets of the tall *Lobelias*. These, again, are grown in rich abundance, and some I observed even planted right into the water in pond edgings, where they were doing finely. It will be interesting to see in this case whether the plants, thus made aquatics, seed as freely as they do under somewhat similar treatment at Sandhurst Lodge.—A. D.

Ageratum Perle Bleu.—If those who like soft blues in their flower gardens for margins or carpets, and dislike blue *Lobelias*—the most unsatisfactory of all summer bedders—would use this beautiful dwarf and continuous-blooming *Ageratum* they would have the very best thing of its kind. I have seen various *Ageratums* in gardens, generally dwarf, irregular and unreliable, and not infrequently going blind and throwing gross leafage only. I have seen this *Perle Bleu* in two gardens, and in one of these it was known under another name. Its average height after a first pegging is 6 inches. The plants can be propagated best in the spring, old ones being lifted, potted, and kept through the winter in a greenhouse to furnish stock.—A. D.

Hardy flowers from Winchmore Hill.—I send you some seedlings of *Aster Amellus*. Beauty is very fine, but of course a small spray cannot convey the slightest idea of its beauty. My plants, which are nearly 3 feet through, are lovely. *Helenium pumilum magnificum*, which I sent you last week, is the very finest plant I have in flower now, growing under 3 feet and in bloom for several months: it is one of my seedlings. *Tritoma Macowani* (Perry's variety) is also very distinct. I think a dwarf race of *Tritomas* would be very useful, and I intend trying to make a collection. I have a fine batch of seedlings and some very distinct, striking forms. *Gypsophila Rokejeka* I know nothing of. It is a true perennial, hardy, and a very striking and useful plant: it is very late flowering, and grows about 4 feet high.—AMOS PERRY.

Campanula pyramidalis.—Seeing the great beauty and general decorative value of this fine old plant, the question seems naturally forced upon one whether anything approaching an adequate use is made of so good a subject in the garden generally. The plant in question has no equal, and a subject so unique may at once be

regarded with some favour. Doubtless this was so when the fine old charming Chimney Bell-flower was more of a novelty than it is to-day, yet the plant has lost nothing of its old-time beauty and effectiveness, and is as still worth special care as ever it was. In some gardens special care is given the plant, and it is grown in considerable numbers in pots with excellent effect. In the open garden, where a mixed bed of it would prove almost a unique feature, the plant is rarely even tolerated. A few days since, however, I noted plants of it at Gannersbury House growing in near proximity to a Yew hedge, the effect being a general lighting-up, as it were, of this usually sombre tree. It is true the plants do not flower the first season when raised from seeds, but if not sown too early in the year they would make splendid examples and produce flowers in quite a wholesale sort of way the following summer. In the year of growth from the seedling any bed so planted with them may be beautified with such things as Gladioli, Tigridias, Hyacinthus candicans, or the like—anything, in fact, that would not too greatly rob the soil of its nourishment. Thus grown, I feel sure the old Chimney Campanula would prove most effective, especially if planted in its varying shades of blue and white.—E. J.

NOTES AND QUESTIONS.—FLOWER.

Zauschneria californica.—I have two objections to this very beautiful Californian herbaceous plant. One is that unless in dry, sunny seasons like the present it cannot be got to flower; the other is that, owing to its underground growth, it is apt to assert itself too strongly, and requires a good deal to be taken away every year. In seasons like the present it is, however, delightful.—DELTA.

Agapanthus umbellatus.—This African Lily is deserving of greater attention by planters for the decoration of the rock garden in August and September than it at present receives. Plants with blue flowers in the outdoor garden are at all times scarce, especially so during the months named; therefore, any that succeed are deserving of attention. The small blue flowers are produced in umbels on stems 2 feet high.—E. M.

Lobelia cardinalis.—The finest examples of this herbaceous Lobelia I have ever seen I noted last month at Blicking Hall, in Norfolk. The flower-spikes were 6 feet 6 inches high and very stout. Growing in a mass in the flower garden there, surrounded by well-kept grass, this bed was a sight to remember. The plants were mainly restricted to one stem, which of course encouraged taller growth. We do not see nearly enough of this plant in gardens, certainly not so much as its merits deserve.—E. M.

Lilium auratum platyphyllum.—I recently saw a charming group of this Lily growing in Lord Battersea's garden in Norfolk. The clump has been established four years, and certainly made a grand display in the month of August, many of the stems being 8 feet high. The bulbs were growing in an angle of the mansion having a north-western aspect which provided partial shade. To these cool and moist conditions Mr. Clemence, the gardener, attributes much of the success obtained in growing this variety of *L. auratum*.—E. M.

Lilium speciosum Melpomene.—This, I think, is the most brilliantly coloured of all the varieties of this beautiful class of Japanese Lilies. It has, moreover, the advantage of being very vigorous in habit. My clump of it seems to have stood the drought well, and has been in its present position for three years. All the varieties of the speciosum tribe are very valuable for autumn flowering, and, although not so showy as auratum, are very beautiful both in form and colouring, while their perfume is delicate and not of the overpowering strength of their more showy relative.—D.

Dwarf French Marigolds as hot-weather plants.—I have not seen any plant that has stood the heat and drought so well as the dwarf double yellow Marigold (*Calendula aurea floribunda*). I have a number of plants in the hottest and driest part of my garden, and while everything else about them is literally roasted up, the Marigolds are fresh and green and bloom abundantly, and the blossoms are fully double. The dense foliage seems to keep the soil cool about the roots, preventing that amount of evapora-

tion which during such weather happens in the case of soil more openly exposed to the action of the sun.—R. D.

DESTROYERS.

WASPS.

As a slight addition to the interesting article on wasps and their destruction, especially with reference to the paragraph as to prizes for queen wasps at local shows, I should like to again advance a suggestion made some two or three years ago when the insects were very troublesome, that parish councils might be induced to take the matter in hand and offer a slight remuneration both for the finding and destruction of nests in their respective areas. War is generally waged against them in the majority of private places, but outside the boundary of these little is done in the way of destruction, and the proportion of nests annually destroyed in any given district is necessarily small. We read this season from many places that market growers of fruit complain greatly of the loss experienced from their attacks, and tradesmen whose wares are attractive find them an intolerable nuisance. It is therefore only reasonable for the gardener to ask for a little co-operation in the way of extermination. If the wasp was fully alive to its power of annoyance and made ample use of the same, fruit gathering this year would be a dangerous business; it is, fortunately (popular opinion notwithstanding), not a combative insect unless much provoked, and if care is exercised there is not much danger of stings. I see Mr. Strugnell mentions damage done to Pears. Has he noticed if wasps are altogether responsible for this or if they follow in the wake of tits? The latter is the case with me, the birds first tapping the fruit and the wasps only too ready to take advantage of the perforation. This season with nets all along the Pear wall so fastened that birds cannot find an entrance the fruit is sound and wasps are absent. So far as the softer fruits are concerned, bees at this season of the year are quite as destructive as wasps. Fortunately, the later Peaches and Nectarines, as the Admirables and Humboldt, are both firmer in flesh and tougher in skin than the majority of the earlier sorts. I have now made a clean sweep of the earwigs, and those mischievous insects are no longer responsible for a first tapping of ripening fruit.—E. BEKRELL.

—The number of wasps in Lincolnshire this summer amounts almost to a plague. In some parts of the district so numerous are they as to be perfectly intolerable. In the gardens and orchards they have made much havoc among the fruit, especially Plums, and much of it has been rendered unsaleable.

—These have been terribly destructive in this part of the country, and it is many years since they were so numerous as they have been this season. In the early part of the summer we were congratulating ourselves on their apparent scarcity, but as soon as the hot weather set in they appeared literally in swarms. This, it must be said, was a matter for great surprise, seeing that steps are taken every year to reduce their numbers as far as possible by taking all the nests that can be found within a radius of a mile from these gardens. However, when they put in an appearance a diligent search led to over 100 nests being found in a fortnight, and since then a great many more have been found in the park, plantations, and fields adjacent to the gardens. These have all been destroyed by means of squibs made of brown paper and rock powder, the fumes of which when the explosion takes place soon settle accounts with the wasps and enable the nests to be dug out directly afterwards. It should be added that a piece of turf or a spadeful of soil is placed over the mouth of the nest to render the escape of the fumes impossible. The nests are marked during the day with a peeled stick or some such distinguishing sign, and then a man and boy go round and take them after dusk. As an incentive I give 4d. for each nest destroyed,

and by so doing have the satisfaction of knowing that all are got rid of within a reasonable limit. If all landowners would do this their numbers would be greatly reduced, and it would also go a long way towards practically exterminating them if followed up successfully for a few seasons.—A. W., *Stob Edith, Herford.*

Birds & insects.—During the present summer insect pests of all kinds have been unusually abundant, for, favoured by fine bright weather and a remarkably still, warm atmosphere, they have led a chummed life, and for weeks past cobwebs and exceedingly large spiders have completely interlaced twigs and branches, until one had to force his way through the branches of fruit trees as if a light gauze net were in front of him. Then the number of white butterflies was remarkable, and, as might be expected, was followed by such a plague of caterpillars that green crops have disappeared and only the skeleton of the leaves is left to mark the spot where green crops lately stood. All this mischief to gardens is mostly due to the long-protracted drought, which has not only favoured the multiplication of insect pests to an enormous extent, but has also brought vegetable crops into a weakly condition, so that they are unable to grow away from their enemies. There is yet another reason that to my idea has greatly favoured insect enemies, and that is the wanton destruction of birds that live mostly on insects. Birds that used only a few years ago to be very plentiful are now getting rare by reason of wholesale slaughter on the coast of this and other countries. Even our own native birds are getting very scarce. There is little doubt that, although some of them are troublesome at seed time and during fruit harvest, they exist the greater part of the year on insects, and we are now paying the penalty of destroying them.—J. G., *Gosport.*

KITCHEN GARDEN.

EARLY POTATOES.

I HAVE lifted the main lot of early Potatoes to-day (September 1). The tops were scarcely ripe, but the skins of the Potatoes are firm. They were planted the middle week in April in rows 3 feet apart on well-cultivated land in an old kitchen garden. The only manurial assistance given was a good sprinkling of charred garden refuse up each row when planting; otherwise the ground was all treated alike. I usually plant the main lot of Brussels Sprouts between the rows of early Potatoes, hence their being put 3 feet apart. Since the late soaking rains the sprouts have grown very fast; for this reason I lifted the Potatoes before they were fully ripe. I give the weight of tubers per row, which were of equal length, viz., 18 yards. I am glad to say I saw no signs of disease. (1) Racehorse, per row, 6½ st.; (2) English Beauty, 7 st.; (3) Veitch's Ashleaf, 5½ st.; (4) Forerunner, 5 st.; (5) Corduke, 6 st.; (6) Sharpe's Victor, 3 st.; (7) Sandringham Kidney, 6½ st.; (8) Rivers' Royal Ashleaf, 4½ st. No. 1 is a selection of my own, which I have grown for many years. No. 2 is a first-rate heavy-cropping early Potato; the quality is good if not used too early in the season. In this respect it does not come up to some of the Ashleaved varieties. I tried it in pots last spring, and it was the first fit to use. At that season of the year (April) quality is not so much noticed, perhaps, as later on when the outdoor crops come in. Anyhow, those of your readers who have not grown English Beauty may fitly do so. No. 3 is an old friend I should not like to be without, though it does not crop so well with me as No. 1, which was a selection from it. No. 4 is a useful kind on some soils in this district. With me it is not so good as others, hence will

not be grown again. No 5 is a heavy-cropping, good selection of the old Ashleaf. It was given to me for trial two years ago. No. 6 is too well known to need description here. For very early crops of high table quality it is still worth a place on a warm south border. No. 7 is also well known to many of your readers as a good selection of Ashleaf. My stock has been grown here for twenty years. It is very similar in all respects to No. 3, viz., Veitch's Early Ashleaf.

H. J. CLAYTON.

Grimston, Tadcaster.

Lettuce in hot weather.—Few things have been grown under more difficulties this season than the salads, Lettuces especially having suffered badly. In many gardens where the old system of transplanting is carried out failures will have been plentiful, as the plants, unless grown where sown, cannot stand the heat and drought. My best Cos is Intermediate, a cross between the Cos and Cabbage, having an upright growth and remarkably solid heart, which is of fine quality and remains firm for a long time. The leaves are of a bronzy colour and very succulent. Another better-known Lettuce and specially good in such summers as we have just experienced is Continuity. I have had two or more distinct types of the latter, but the best is a dark-leaved dwarf form.—G. W.

Lifting Potatoes.—Many of our late Potatoes are smaller than usual this year, owing to the heat and drought. There will be no gain after this date—the end of September—in leaving the tubers in the soil should we get a spell of wet weather after such a protracted drought. I am aware in some places late planting is advised, but I fail to see the value of it. Even in the most favourable seasons late planting is not advisable, as the tubers planted early are freer from disease, and in seasons of drought, by getting a firm hold of the soil, make a better growth. Of course, by lifting as now advised more care will be needed in storing. I find by placing in heaps where grown, merely covering over lightly for a few weeks, it is an easy matter to examine the tubers. I prefer clamping to placing in rooms or cellars. Late Potatoes keep much better stored as advised. If desired, seed may be selected previous to clamping or placed on one side when placing in bulk.—S. M.

Onions and Cabbages.—I noticed, when recently at Madresfield Court, that the same rotation in relation to these vegetables existed there that may be seen at Hackwood Park. At the former place I observed the summer Onion crop—a very good one, although the bulbs were not large—was being cleared off and laid out on a gravel floor to fully ripen. So soon as the ground was cleared, a man ran one of the Wilson Junior wheeled hoes over it, stirring the surface fully 2 inches. Then another labourer followed with what I had never before seen similarly employed, a big iron-toothed hay or corn rake, which drew off all the coarser weeds. That would leave the surface ready for at once planting with Cabbages. But here it is not the case, as at Hackwood, to solely alternate Onions and Cabbages, as the Onions follow Celery, and Cabbages follow the Onions, thus making an admirable rotation.—A. B.

Planting Cabbage.—Owing to heat and drought I find the seedlings this season poor, no matter how well attended to in the way of moisture. To ensure a clean plant it is well to take a little extra trouble at planting. A thick solution of soot and lime, or, what is better, finely powdered sulphur, will do much good if the plants are dipped and all parts of the leafage covered with the mixture. There are other evils to contend with this season, and one, I fear, will make sad havoc among the plants, viz., blindness, which is very prevalent this year owing to the great heat. Fully half my plants are useless from this cause. It is very annoying, as the season being so far advanced one cannot make up lost time. Some

good stock for later use may yet be secured by sowing for that purpose. Of course for first spring cutting the July plants must provide the supply. Finding the second sowing germinated badly, I sowed at the end of August some seed in cold frames, kept it shaded at the start, and have secured a lot of strong seedlings. These will be pricked out into rows when we get a change in the weather. The plants by the end of November will be sturdy and fit for planting at the end of February or early in March. It may be thought a supply could be obtained by sowing in heat early in the year, but this sowing will be much later. In seasons of scarcity I have sown this month in a cold frame and exposed the plants when possible. The Cabbage crop from April to the end of June is so important that it cannot be neglected, and difficulties met now will save time early in the new year.—S. M.

Potato lifting.—Under the most favourable conditions as far as weather is concerned, the lifting of Potatoes is going on apace, and when the nature of the season is taken into account it is astonishing how well the crops are turning out. The tubers are large, well ripened, and very clean, while the cooking qualities of all that have been tested up to the present time are very satisfactory. To judge by the appearance of the tubers as they lie on the ground, a casual observer would think they had had an abundance of moisture to support growth right through the season, whereas the opposite has been the case. The last occasion on which rain fell here in sufficient quantity to thoroughly moisten the ground was during the last week of May and the first week in June; since then we have only been favoured with an occasional shower. Such being the case, the results are very satisfactory, and it proves that heavy crops may, and can, be grown even in a season of drought on deeply-stirred ground. With one exception the crops alluded to have been grown on soil so treated, and I have found this "deep stirring" to be of the utmost value, not only for Potatoes, but other crops as well, during the past three seasons, when similar climatic conditions have had to be contended with. It is also pleasing to note that disease is, if not entirely absent, certainly of a trifling character, as but a few tubers have been found to be affected. The crops as lifted are being carried direct to the Potato store, the tubers being laid out thinly until quite cool and all danger of sweating is past, when they are placed thickly together. When such a convenience as a Potato store exists, this is the best way to manage Potatoes, as they can always be conveniently overhauled, independently of the weather, such work affording employment on wet days, or when the hands are unable to get on with outdoor work.—A. W.

The autumn vegetable supply.—With the majority of growers the outlook as regards the autumn supply of vegetables is none too rosy, and in nine cases out of ten this is unavoidable, as the soil during August and September has been in such a parched condition that growth has been much retarded. In many cases the water supply has been none too great; in others the labour to apply the same far too limited; while in many cases moisture when given is, owing to the nature of the soil, so soon spent that it does little good, merely keeping the plants alive. I fear the late Pea crop will be poor. I was obliged to root up the plants, as they presented a sorry spectacle in spite of the moisture given. Peas will not thrive with the thermometer at nearly 90° in the shade with the best attention if the soil is resting on a hot gravel subsoil. Salads for present use are none too plentiful. With cooler nights and rain matters will soon right themselves, as the plants grow quickly. One cannot do better than hoe freely and feed with liquid to get rapid growth. Lettuces delight in a cool, rich root-run. Cauliflowers are scarce and far from clean. Though these plants are so tender, they suffer from heat sooner than most vegetables if there is an absence of moisture. Much may be done to encourage growth in Cauliflowers and the early autumn Broccoli by mulching with

litter or spent manure. The Brassicas of most kinds are poor, and Coleworts have not made the progress one usually sees. Spinach, owing to the heat, is poor, but with cooler nights and moisture it will soon recover. Seed sown now rather thinly will make up for losses in the spring. The best autumn vegetables this season are those that have been planted in land not dug. Of course, with a genial rainfall and the earth in a warm condition growth now will be rapid. The autumn is now so near, that there is a danger of such tender growth being cut down by frost, so that the outlook is none too promising.—G. WYTHES.

NOTES AND QUESTIONS.—KITCHEN.

Tomato Up-to-Date.—Mr. Allau, of Gunton Park Gardens, thinks highly of this Tomato, and certainly from what I saw of it at the end of August he has just cause. The plants were growing in a deep pit, trained on wires close to the glass. The crop was enormous, clusters hanging quite thickly from the base to the top. In one cluster I counted two dozen fruits, and there was plenty of bunches with eighteen fruits. The fruit is of medium size, quite smooth and round.—E. M.

Hicks' Hardy Cos Lettuce.—Gardeners do not often grow this Lettuce, judging from the few one sees of it in various gardens. I saw a magnificent batch of it in the Gunton Park Gardens at the end of August. When we remember the extreme dryness experienced at that season it says much for this Lettuce as a drought resister. The heads in question were large, solid and crisp. As a winter variety, too, this is one of the best, rivalling even the old Bath Cos or even Brown Champion.—E. M.

Tomato Melton Seeding.—This appears to be a desirable variety. Mr. Shingler, gardener at Melton Constable, raised this variety by crossing Nisbet's Victoria and Perfection. As a free-fruiting, medium-sized variety it has much to commend it. The colour is bright and the flavour all that can be desired. The Tomatoes here are grown in 8-inch pots plunged in leaves and soil. The roots grow through the bottom of the pots, thus giving a greater freedom of growth, yet sufficient check to induce the formation of a full crop of fruit.—E. M.

GARDEN FLORA.

PLATE 1190.

THREE WINTER-FLOWERING HEATHS.

(WITH A COLOURED PLATE.*)

WITH such winters as the past one might wholly change the aspect of our gardens in winter by the bold artistic use of several of the Heaths of Europe, which often bloom at dawn of spring, but in the past winter covered the ground with colour as pretty as any of the flowers of summer. The first of these is the Portuguese *E. codonodes*, a most delicate, beautiful shrub, in our country flowering from December, and a great aid in southern and mild districts. It is more delicate in colour than the true Heath with its little bright buds, and is a very charming shrub. Secondly, *E. mediterranea hybrida*, which is probably a cross between the alpine forest Heath, *E. carnea*, and either the true Heath or the Mediterranean Heath. It is quite a new and most precious thing for gardens generally, and last winter it flowered with us in the south of London the whole of the winter—that is, from the beginning of December it remained far into the spring, a most delicate colour. Lastly, our old friend *E. carnea*, which has long proved its value, though it is not often used in the most effective and artistic ways. The best form of this is a very bright, vigorous plant, which is always in bloom at the very dawn of

* Drawn for THE GARDEN at Gravetye Manor by H. G. Moon. Lithographed and printed by J. L. Goffart.

spring after the hardest winters, and in mild winters like the past very often in showy flower.

It is needless to say more of the value of plants more precious perhaps than those of any country, hardy, easily increased, and useful in every garden.

THE WEEK'S WORK.

HARDY FRUIT.

NEW STRAWBERRY PLANTATIONS.—In districts affected by the drought, both old beds and young ones, too, will need considerable attention still for watering. The advocates of annual planting will not otherwise have found this season the best possible one for establishing their young stock. The older beds, on the other hand, if well attended to previously will have more enduring properties with the roots lower down, and hence both cooler and moister. The young plants even during such a season as the present would have been greatly benefited by a light mulching; it would, however, have to extend over all the ground, otherwise the birds would soon remove it. Planting rather deeper during drought will be found the safer plan, that is, drawing drills and planting in them. I shall not hesitate to make young plantations this year during October from pot plants, but not otherwise. We cannot possibly, one may fairly surmise, be now very far off from rain in sufficient quantity to benefit vegetation, after which these young plants will soon take root freely. Young plantations which are seen not to be progressing as they should do may have the cause attributed to lack of moisture. Keep the hoe at work amongst these, or a rake, so as to break the surface of the soil, and water them liberally. Those who have taken the pains to tread around their young plants when put out will now find a benefit therefrom, plants so treated being less liable to suffer from want of moisture. Older beds, although they will hold out longer, will also be likely to suffer, especially if the runners were not cleared off after fruiting, but where the mulching was left upon these beds, benefit will have been accorded them. In every case of Strawberry culture the advice given is to water liberally, so that the crowns for next season's fruiting may be fully developed, otherwise the future prospects will be but poor.

STRAWBERRIES IN POTS.—So far in my own case the progress of these has been variable. On the one hand, such varieties as La Grosse Suerée, Vicomtesse Héricart de Thury, Keens' Seedling, and Latest of All have each done remarkably well, making a sturdy growth with the foliage of that dark colour one likes to see. On the other hand, Royal Sovereign has not done so well; the foliage has been disposed to curl with occasional symptoms of mildew, which is stopped as soon as possible by dusting with sulphur. The treatment to each and all has been exactly the same, so it is either the season or some peculiarity in the variety which is the cause, I think. The crowns of the last-named, however, are plumping up well, so there need not be any real cause of anxiety for next spring. Let all pot Strawberries now have the maximum of light and air. Where the room was possibly limited as regards standing accommodation earlier in the season, an effort should now be made to re-arrange them at greater distances apart. A turn about with the ashes raked over will do no harm, rather otherwise. At the same time look to the drainage and remove both runners and weeds. Where the plants are thoroughly well established and are seen to dry out quickly an occasional dose of liquid manure will assist them, but do not use it other than quite clear, so as to prevent any settlement on the surface. Watch for worms at the same time and catch them if possible. When room is scarce, a line of these pot plants can often be stood around the garden paths or upon boards on the quarters.

LATE STRAWBERRIES IN THE OPEN AND IN POTS.—These have done very well this season. Royal

Sovereign has been in picking since the middle of August, and the beds still supply an occasional dish. Vicomtesse H. de Thury has not done so well from some cause. St. Joseph bids fair to be a decided acquisition. Plants of this Strawberry, which showed a good crop of flower-trusses and ripened their fruits with the first earlies, as Royal Sovereign, are now bearing an even greater profusion, the earlier ones ripening their fruits, the later ones coming into flower. Out of doors the flavour is now brisk and sub-acid; earlier in the season it was much sweeter. This can, of course, be easily accounted for late in the season. It is a most prolific Strawberry with the alpine character of freedom in bearing and continuity imparted into it, and will, no doubt, find favour in many gardens, especially where a prolonged succession of Strawberries is required. Plants of this kind in pots are now housed, whilst those of Louis Gauthier are being got into frames owing to want of room in the Strawberry houses. Both kinds are bearing good crops, and will be the means of extending the Strawberry season considerably in conjunction with the alpine varieties now in good bearing outside. These latter have up to the present had to be watered every week or two. This is done by means of the hose and a fine spray jet, by which means the water falls in the form of a gentle shower upon the plants. This watering whilst the plants are in a fruit-bearing condition neither affects the flavour of, nor causes any decay in the fruits. The seedling alpine raised last April are now quite fit to plant out into their fruiting quarters, having, with regular attention to watering, made excellent growth. This work will be done by the middle of the month, by which time I hope to have the ground at disposal. In preparing the ground for planting, pains should be taken not to leave it at all lumpy. It should be well broken to pieces during the process of digging or forking over as the case may be.

WATERING OUTSIDE.—This work is still being attended to most attention being given, as a matter of course, to trees still carrying their crops, but all need attention where the crops have been good. Where the watering has been continued through the drought the results are singularly manifest both in the colour of the foliage and in the size of the fruits. This applies to all kinds of fruit, but to Apples, Pears, and Cherries in particular. The fruit-buds for next season upon Cherries and Apples are already well plumped up, the former trees going steadily to rest with an entire absence of rank growth, the latter showing some signs of a secondary growth, which will be stopped again. This work of watering is an all-important matter upon light or well-drained—too well possibly—soils, and should be followed up until penetrating rains fall. The trees which show most signs of distress with me are those upon grass land where the trees are old, having been planted in the early fifties. Mere superficial watering will not suffice. Do the work thoroughly well and in the end it will take but little longer. The weather of the past few weeks has been conducive to the spread of red spider. Where this pest is noted, pursue the usual remedy of drenching the trees, using in bad cases some sulphur incorporated with the water.

WATERING INSIDE BORDERS.—The same remarks and advice apply with equal force here; in fact, more so when dealing with the first early Peaches and Nectarines, which, although the trees may now be casting their foliage, must not be allowed to get dry at the roots, as herein lies a fertile source of bud-dropping. It must not be inferred that because the leaves fall thus early it is altogether caused by natural conditions. It may have been brought about by want of moisture; if so, more is the pity as far as next season's crop is concerned. The advice given is to carefully examine the borders, and test them if need be as to their condition, not hesitating afterwards to water well if occasion requires it. Vines also are none the better for being kept too dry at the roots. To a certain extent in every case we should imitate Nature, for do we not have some

of our heavier falls of rain during the resting period? Of course, what has to be taken into consideration is the condition as regards make up of the borders. If the drainage be good, watering is perfectly safe. On the other hand, upon heavy, non-drained soils it must be looked into carefully. What has to be guarded against is the premature ripening or falling of the leaves before they have performed all of their functions and imparted to the now dormant buds some of their good properties. HORTUS.

KITCHEN GARDEN.

NECESSARY WORK. Owing to the drought, weeds have not been troublesome, but with cooler days and, I trust, a genial rainfall there will be great activity, and the hoe will need to be kept going to keep down weeds, as later in the autumn it is a difficult matter to get rid of them owing to lack of sun to dry them up. Any arrears of seed-sowing should be undertaken at once, and, sown thinly, growth will be active owing to the warmth in the soil. I fear there will be gaps in the autumn sowings, as I find the earliest sown Cabbage plants have gone blind owing to the heat and drought. It is always well to have plenty of plants to fall back upon, as then the variety can mostly be relied upon, and if there is a good stock it saves time. It is not too late to sow Turnips for use in the spring. Sow thinly and give as open a position as possible. A few drills of Long Standing Spinach sown now will come in for use a month in advance of the spring sown, but it will need good culture and to be kept free from slugs. Carrots sown a few weeks back to draw through the winter in a young state should be thinned if too thick, but Carrots will do much closer now than in the summer. After thinning, which is best done in showery weather, give the plants some food in the way of a dressing of soot or a quick-acting fertiliser. Potatoes of most kinds should now be lifted. I fail to see the utility of leaving late kinds any longer in the soil, as after so much heat and drought they will grow out badly, as even before the change in the weather there was some evidence of disease, and by lifting this will be checked. We very often get much rain after a long spell of dry weather, and the lifting can be done better whilst the soil is dry. For seed there need be no haste in sowing, as if the sets are greened so much the better, as they will keep sounder, the skin being hardened. For late Potatoes in quantity I would advise clamping, and with the soil in workable condition there is no need to expose the tubers, as they will be dry enough to place in hulk. Those showing the least disease should be placed in smaller heaps so that they may be often looked over or used up quickly. Ground as it goes out of cultivation should be levelled over for the rains to reach the lower portion, all decaying matter being burnt and the hoe occasionally run over the surface to keep it clean.

ENDIVE.—It will be well to plant out at this date a good breadth of Endive, as not only is it good for salad, but also as a vegetable if the large-leaved Batavian is grown for that purpose. Up to this date in the southern parts of the country planting has been delayed owing to drought and heat, and though full late to set out for early winter supplies, the plants will soon make up lost time if placed in well-manured land and kept well supplied with moisture. The large Improved Green should also get a favourable position for early autumn supplies. This is harder than the Moss Curled, and being a firm hearting variety is useful. Those who have cold frames in which to winter Endive may with advantage plant the tender kinds in such, as in these protection from heavy rains and frost in the late autumn may be given. Last winter the large-leaved Batavian stood the winter under a west wall. For the early spring supply it will be well to plant medium-sized sturdy seedlings, as should the winter be severe they can be lifted or covered with litter or Bracken in their growing quarters.

LETTUCE.—Seedlings for early autumn supplies are best left in their growing quarters if the supply is none too plentiful. The plants, if at all thick, may be thinned. The thinnings, if lifted carefully, will make a succession to the plants left. Owing to the heat and drought, I in a previous calendar advised sowing thinly in drills in order to avoid planting out, but now with cooler weather and more moisture the plants will continue to grow till the autumn, and though they will not make the large blanched heads so much desired, the smaller ones will be useful for salad. Much better results will follow planting if the seedlings are lifted with a ball. If well watered in they soon make a start. I have found these Lettuces, though small, are far more hardy than the larger ones with blanched hearts, these being the first to feel the effects of frost and soon decaying unless housed, whereas there is no hurry with smaller plants in a green state. It is useless to put out at this late period plants that have been crowded in seed beds. For spring supplies the cultivator in many cases relies on the seed sown in August, but this year, owing to bad germination, my plants sown towards the end of the month are very scarce. It may happen that the supply even now is none too large, and my advice is to sow at once in cold frames. It is too late to sow in the open with a certainty of success, so I advise sowing in frames, as the Lettuce in the spring is of great value, and plants sown now will turn in much sooner than those raised in heat early in the year. In winter at times mildew attacks the seedlings if kept too close, but dry wood ashes, with a little sulphur, soon check the disease.

CUCUMBERS.—A few weeks ago I noted the importance of a good house of Cucumbers for what may be termed the autumn supply. The plants then put into their fruiting quarters will now make good progress, and with cooler nights more warmth will be needed. I find it a saving to cover the glass at night from this date, as this saves hard firing, and the plants grown thus are stronger in consequence. Plants coming into fruit will now need a temperature of 70° at night and 20° higher by day, with sun-heat and in bright weather ample supplies of moisture. The fruits grown in a close, moist house are far superior in quality to those grown slowly in a lower temperature with more ventilation. With an increased temperature from fire-heat more moisture will be needed in the house, and to keep the plants free of thrips or spider I would advise placing a little liquid manure in the pans. This will assist in building up healthy foliage. Avoid overcropping at the start, and at all times encourage the formation of new wood, as upon the latter will depend the vitality of the plants. Feed freely when giving moisture. I prefer liquid manure. Bone-meal may be used to advantage when giving new surface-dressings, and soot also in small quantities to give the leaves colour. It is well to cut the fruits daily, and when nearly full grown they will keep fresh for days if placed in water in a cool place. I have noted the importance of obtaining new wood, but this will be weak if too many fruits are allowed on the plant at one time. It is well to encourage new surface-roots, and a little top-dressing given every fortnight is the best. The plants delight in a rich root-run. Avoid leaf-soil which is not good, as it causes a quick growth at the start, but is wanting when the roots make an increased demand. Winter fruiters will need to be placed in their pots or fruiting quarters. The compost for these may be fibrous loam, say one half or more, and a goodly portion of wood ashes, some broken charcoal, and spent Mushroom manure. My plants are now in 6-inch pots and kept near the glass to make them sturdy. I do not fruit these till December, relying on the autumn plants.

HERBS.—All kinds of herbs should now be tied up neatly and suspended where air can circulate freely, as if in a damp place the flavour is impaired. Sweet and Bush Basil, sown late for autumn and winter use, should now be cut and

dried. If Basil is needed in a green state through the winter months, a box of seed sown in frames now and in colder weather in warm houses will provide a supply. To keep it up, sowings should be made every three weeks, and later on care taken that the plants do not damp, as they do badly if given too much moisture. The summer Savory will now need cutting. Sage may be cut and dried, and Mint needed for forcing should be cut close to the soil—I mean this year's growth. It will then start earlier when placed indoors to force. Parsley sown for next spring's supply has had a hard time owing to drought. Thinning should not be longer delayed, but after thinning give moisture to settle the soil round the roots, and give a dressing of soot in showery weather. Earlier-sown plants will pay for food in the shape of soot or liquid manure, and for winter use, if cut over now, will make new growth. S. M.

FRUIT AND VEGETABLE CROPS.

SCOTLAND.

Tynninghame.—Crops of fruit and vegetables alike, notwithstanding the erratic nature of the weather, have turned out well. Apples, Apricots, and Plums are, of large fruits, better than Pears. All are of better quality than usual. The earlier sorts of Apricots and Plums at time of writing are ripe, and Codlin Apples are fit to use. Small fruits have been a very heavy crop, and generally of fine quality, the only exception having been Strawberries, which, though a heavy crop, have yielded smaller fruit than usual.

The chief vegetable crops, including Peas, Cauliflowers, Potatoes, Lettuces, Onions, Broccoli, have been better than usual, and the crops that have yet to finish, such, for instance, as Celery, late Peas and Cauliflowers, Potatoes, Leeks, and Brussels Sprouts, are all looking healthy and making a rapid growth. On the whole 1898 is turning out a good year.—R. P. BROTHERSTON.

Ladykirk, Berwick.—Apricots and Peaches are above average here; Plums are deficient on walls, both on east and west aspects, but standards are heavily laden; Pears are very scarce all over; Apples are good, also Cherries; small fruits very abundant and good.

Taking into consideration the long drought we have had here, the vegetable crops have done very well. Early Potatoes were small in size owing to ripening too rapidly.—J. GEMMELL.

Glamis Castle, Forfar.—Fruit crops are under the average with me, and owing to the protracted drought the bushes and trees are suffering very much from the attacks of aphid, especially on light soils. The first pickings of Strawberries were good, being large and of fine quality, but later pickings have been very small. Gooseberries are a very good crop and of fine quality. Currants are only fair, and Cherries an average crop. Plums are a poor crop, and Pears a failure altogether. Apples are only a casual crop, some young trees of Lord Grosvenor, Duchess of Oldenburg, and Keswick Codlin are carrying heavy crops of fine fruit, while varieties such as Ecklinville Seedling, Northern Dumpling, and Beauty of Moray, usually so fine, are this season a complete failure.

Vegetables are good, except Carrots, these having gone off with the maggot. Early Potatoes are a good crop, of fine quality, but the tubers are small.—THOS. WILSON.

The Gardens, The Glen, N.B.—In this neighbourhood Apples are a good crop on walls; on standards thin. Apricots are a failure; Cherries abundant; Plums a failure; Strawberries a grand crop and of very good quality. Gooseberries, Currants and Raspberries are over average.—W. MCINTYRE.

Balcarres, Fife.—Apples are a fair crop. Lord Sulfield, Keswick Codlin, Northern Dumpling, Bramley's Seedling, James Welsh, East Lothian Seedling, James Grieve and Worcester

Pearmain are very good. Pears and Plums are under average. Early Cherries are plentiful, but very small; Morellos very good. Peaches and Apricots are under average and small. Small fruits are very good. Strawberries have been good. Of Strawberries, Royal Sovereign, Garibaldi, Duke of Edinburgh and Sir Joseph Paxton are the best. Of new varieties, Leader and Veitch's Perfection are good. The month of May was very cold and frosty and all crops have suffered from the long drought.—E. TATE.

Brechin Castle, Forfar.—With the exception of Pears the fruit crop in the gardens here is very fair. Apples are an average crop; Plums rather under the average; small fruits are abundant. Strawberries are a heavy crop and have been gathered in fine condition. Royal Sovereign has been very fine, fruit large and flavour good. Garibaldi and Elton Pine are the sorts I mostly depend on. Latest of All is a great cropper, with fruit of enormous size, but here at least the flavour is very deficient.

Although we have had a very dry summer, vegetables are doing fairly well. Early Cauliflower has not done very well, but with rain now the autumn supply promises to be good. Peas are a good crop, haulm shorter than usual. Onions and Carrots have a healthy appearance, and French Beans look well. Early Potatoes are a fair crop, of fine quality, but of medium size, and later sorts are good. As yet there is no appearance of disease.—W. McDOWALL.

Eglinton Castle, Irvine.—The small fruit crops in this garden are very good both in quality and quantity. Strawberries have been extra fine, also Black Currants. Morello Cherries and Victoria Plums on walls are also very heavy crops. Other varieties of Cherries and Plums are not so heavy, but of good quality. Apples are a very thin crop, and Pears are quite a failure. Peaches outdoors are hardly worth the trouble; still, we have a few on some trees.—W. PRIEST.

Erskine.—Apples are better than last year, and a good crop in this neighbourhood. Pears are a poor crop here. Plums are good on standards, but poor on walls; in some places near here a failure; Cherries an average crop; Peaches under; Apricots under. The small fruits are plentiful and good; Strawberries over an average crop and of good size. Taking the crops all over we have a record year at Erskine.—JAMES M. REID.

Abercainey, Crieff.—Apples are under the average; Pears much under; Plums average on walls, very poor crops on standards, having suffered by frost just after they were set on May 18. Apricots and Peaches are over the average; Cherries over the average. Small fruits are plentiful.

Vegetable crops have been good up to the present, but now stand greatly in need of rain. Peas have done extra well this season, but were soon over owing to the dryness of the ground.—J. C. BROWN.

Lennox Castle, Lennoxtown.—The fruit crops in the gardens here and neighbourhood are generally good. Apples, Pears, and Plums are a fair crop. May Duke and Morello Cherries are very good. Gooseberries, Raspberries, Black, White, and Red Currants are extra good; Strawberries fair.

Vegetables with me are all doing well with the exception of Carrots and Onions, which are suffering from attacks of the maggot, a general complaint in this neighbourhood.—J. TINSLEY.

Blackadder, Berwick.—The fruit crop of 1898 is in this district a good one. With the exception of Pears and Plums, all sorts are above average and of good size and quality. Apples, from the amount of blossom, promised to be equal to the crop of 1896, but I suppose, owing to cold, cutting winds and slight frosts, the blossoms of some varieties were destroyed, which would account for the irregular crop. Some trees are actually breaking down from the weight of fruit, while others have only a few diseased-looking fruits, and the foliage has the appearance of having

passed through fire. Especially is this the case with healthy, free-bearing sorts, such as Manks and Keswick Codlins, Ecklinville Seedling, &c. This is the case with at least the first-named sort at three different places where I have seen it, miles apart. Warner's King, Stirling Castle, and other well-known sorts are, on the other hand, well furnished with fine healthy foliage and fruit. Victoria Plums are a very heavy crop; Green Gages and others below average; Pears much below average. Cherries have been very heavy and of large size. The same may be said of all small fruits. Strawberries, where watering was not persisted in, were unable to perfect more than two-thirds of their crop, but very fine fruits were got from the first gathering.

Vegetables have done fairly well, but in many cases are undersized. Carrots are, I believe, a failure in most places. Other root crops, such as Beet, Parsnips, and Turnips, were very slow to grow in the early season, but latterly have made good progress. The same may be said of the Brassica family. Dwarf and Broad Beans have done very well, the latter, perhaps, not quite so prolific as usual. Peas are a good deal mildewed and go quickly to maturity. Potatoes of the Ashleaf type are of large size and more prolific than I have seen here for several years; no disease has as yet appeared and the quality is all that can be desired.—J. KROSSIDE.

Dalmeny Park, Midlothian.—Everything promising abundance last April, but May and June turned the promise almost upside-down. Apples and Pears especially; but with the fine weather we have had these last four weeks I expect quality to make up for quantity. Apricots good, had to be severely thinned; Apples a fair average crop, Irish Peach, Duchess of Oldenburg, and Stirling Castle heavy crops; Peaches and Nectarines heavy under glass, average on walls; Cherries (dessert) good, Morello (north aspect) very poor; Pears almost blank, except Jargonelle and Beurré Diel, the latter on south aspect, former west aspect; Plums a good crop on east and south aspects; Currants, Black and Red, heavy crops; Gooseberries Hedgehog, Warrington, and Whitesmith very good, Sulphur very poor; Strawberries very good, especially Elton Pine.

Vegetables, all sorts, have done very well these last four weeks.—JOHN MOYES.

Galloway House, Garliestown, Wigtownshire.—The fruit crops in this district are more variable than usual. In some gardens very good crops are to be seen, while in others the fruit is very scarce, especially Apples and Plums, which appear to have suffered most in places according as the successive cold waves in early spring caught the bloom at a critical time. In these gardens the Apple crop is a very fair one; some varieties are heavily cropped and most have a good sprinkling of fruit, which promises to finish off very satisfactorily both in size and colour. The best are Mr. Gladstone, Early Harvest, Worcester Pearmain, Thorne Pippin, James Grieve, King of the Pippins, Cox's Orange Pippin, and of cooking sorts, Warner's King, Bramley's Seedling, Lane's Prince Albert, Lord Grosvenor, Wellington, Duchess of Oldenburg, Galloway Pippin and Loddington Seedling. Pears are very good, but later varieties will have smaller fruit than usual. Jargonelle, Marie Louise, Williams' Bon Chrétien, Princess, Jersey Gratioli, Beurré d'Amanlis and Louise Bonne of Jersey are the best. Plums are turning out much better than was expected a short time ago; the recent heavy rains have cleaned the foliage and given such an impetus to the fruit that quite good crops will now be secured. Victoria and Belle de Septembre are mostly grown here in the open, and both are well cropped. Against walls, Early Rivers, Czar, Kirke's, Denniston's Superb, Lawson's Golden Gage, Jefferson's, Pond's Seedling and Goliath are also very good. Peaches and Nectarines are very light crops, several of the trees being fruitless. The bloom on these was plentiful in its season and the fruit set well, but the cold winds later on caused the foliage to blister to

such an extent that most of it had to be removed, in consequence of which most of the fruit fell from the trees. Dessert Cherries were fair average crops, which ripened up well and free from cracking. Morellos are especially good, being heavy crops and fine fruit. Figs of the Brown Turkey type are very abundant, but being rather later than usual, it will depend very much upon the weather as to their ripening. Castle Kennedy is much earlier than the former, and although not such a sure fruiter, it always ripens its fruit, and this year this is very fine. Strawberries in many places were below the average; it was the same here, as, with the exception of early varieties in favoured positions, they could not be considered a full crop. The light crop was, however, to a great extent compensated for by the dry weather that prevailed when the fruit was ripening, which enabled the crop to be gathered without material loss either from rain or insect pests. Gooseberries were abundant here, and so far as the crop goes were generally good, but in many instances the caterpillar did much damage to the foliage, and so injured the fruit. Black Currants were slightly below the average; the dry weather set in at a critical time for this fruit, and aphids and red spider for a time were rampant. So far I have never discovered a trace of the Black Currant mite in this county, although in some parts of Scotland it has rendered the cultivation of this otherwise profitable fruit a very disappointing one. Red and White Currants were very good, and upon north walls some very fine fruit will continue good for some time. Damsons are not often a success in this part, and this year they are worse than usual, being almost fruitless.

Vegetables of all kinds have done well. Early Potatoes were rather late, but the quantity and quality of the crop were good. The same remark applies to second earlies, but where not dug these are now showing signs of disease in their foliage, though as yet very few affected tubers have been found. Late and field crops are looking well; these are of more diverse varieties than was the case a few years ago, when the renowned Champion held the sway. This, owing to the deterioration of the size and symmetry of the tubers rather than quality, is now being superseded by Maincrop, Magnum Bonum, Bruce, Saxon and others. Early Peas bore a heavy crop; later ones are badly affected with mildew. Onions, Beans, Cauliflowers and all kinds of winter crops have revelled in the heat and moisture of the past month, and plentiful supplies for the autumn and winter months are now assured.—JAMES DAY.

IRELAND.

Belfast Castle.—The fruit crop in this locality is anything but an all-round good one; Apples, Pears and Plums very thin. The trees blossomed splendidly and expectations of an abundant crop ran high, but wet and stormy weather, with hail, destroyed the crop. Bush fruits are fair, also Strawberries, but owing to drought the season was short.

Vegetables are abundant and of good quality.—W. TOTT.

Charleville Forest Gardens, Tullamore, King's Co.—The small fruit has been very abundant here this season. Strawberries, Raspberries, Currants and Gooseberries were simply laden; the Gooseberries I never saw finer, both in size and quantity. Cherries, both sweet and Morello, have been light; Apricots, too, are few. Plums are an average crop. Pears on walls are fair, but standards have very few. Some sorts of Apples, viz., Ecklinville, Peasgood's, Greening's Pippin, King of Pippins, Cox's Orange and Duteh Mignonne, are the only ones carrying a good crop.

The Potato crop all round has suffered very much from disease.—R. MCKENNA.

Tillyra Castle, Ardahan, Co. Galway.—Strawberries were fine, especially Royal Sovereign and Noble. Gooseberries, Currants (Red, White and Black), and Raspberries were very heavy; quite the reverse of last year, when they were light. Pears are scarce, and the crop of Apples

is very light, next to nothing, owing to spring frosts. With regard to Plums, the Victoria is bearing well, none on the other sorts. Peaches outside are fair and Cherries are heavy crops.

Vegetables with me were very good, and I never had finer crops of Potatoes. Up to the present I have not found a diseased tuber. They look well in the country round, though the mode of treatment is not the best. W. O'ROURKE.

Tubberdaly, Edenderry, King's Co. The fruit crops are up to the average. Apples are good; Pears average; Plums under average; Cherries good; Peaches and Nectarines good; Apricots bad; small fruits good; Strawberries average.

Vegetables are good all round. Beans, particularly runners, are late owing to the cold weather experienced in May and first week in June.—D. MCKINNON.

Woodstock, Kilkenny.—The Apple crop in these gardens and neighbourhood is a good average one, trees healthy and fruit promising in quality. Pears, Plums, and Cherries are in general a light crop. Strawberries were a full average crop and excellent in quality; other small fruits abundant and good.

Vegetable crops are also good with me this season, but owing to the mild, moist winter there was more than the usual number of garden pests. Potatoes in both field and garden are a prolific crop and extra good in quality. There is very little disease so far.—WILLIAM GRAY.

Kylemore Castle, Co. Galway.—Apples and Pears are a good average crop; Plums a good crop; Apricots much under the average. Gooseberries, Currants, and Raspberries are a full crop, but Strawberries are only about half a crop.

Vegetables of all kinds are all that could be desired. Potatoes are a fine crop. The much-dreaded blight is much in evidence in low-lying parts, and will seriously affect the later varieties. Where spraying has been done blight has made but little progress.—WILLIAM COMFORT.

Birr Castle, Parsonstown.—The fruit crops in this neighbourhood are indifferent. Apples are a very thin crop; Pears are also a light crop. Plums are fair. Some sorts, such as Victoria, Pond's Seedling, and Early Prolific, are good. Morello Cherries are a good crop. Peaches and Nectarines on open walls are an average crop on some trees. Early Strawberries were a very poor crop, but later sorts were very good. Raspberries are very abundant and fine; Gooseberries and Currants are good average crops; Nuts are also very fair. All sorts of fruit trees blossomed very abundantly, but owing to the late spring frosts and cutting N.E. winds which were so prevalent during the early months of the year the fruit failed to set well.

The Potato crop bids fair to be the best known in this locality for some years past. The tubers are plentiful and good, and so far free from disease.—T. J. HART.

Carton, Maynooth, Co. Kildare.—The fruit crops in the gardens here and neighbourhood are a good average. Apples Irish Peach, Blenheim Orange, King of Pippins, Mère de Ménage, Stirling Castle, Golden Spire, Tower of Glamis, and Keswick Codlin are heavily laden; other varieties a fair crop. Pears Williams' Bon Chrétien, Beurré Bosc, Pitmaston Duchess, Louise Bonne of Jersey, and Glon Morecau are good crops. Cherries of sorts are very good. Damsons are a heavy crop on old trees, but Strawberries are under average. Currants, Red, White, and Black, and Gooseberries are abundant; Raspberries plentiful, but small; Filberts average.

Vegetables are very good. Potatoes never looked better in garden and field.—A. BLACK.

Fota, Cork.—The fruit crops, on the whole, are about an average. Small fruits are heavy crops. The Strawberry season was very short in consequence of the dry weather and great heat. Apples are a fair crop; dessert Apples scarce. Here Cox's Orange Pippin and Sturmer Pippin, which always bear well and on which I rely for the principal dessert Apples, are quite a

failure this year; Kerry Pippin and others are quite as scarce. There are fair crops on the following kinds: Warner's King, Lady Henniker, Loddington Seedling, Lord Grosvenor, Domino, Gascoigne's Seedling, Grenadier, Lane's Prince Albert, Bramley's Seedling, and Small's Admirable. Pears are a half crop, but on light soils very small and deformed in consequence of the summer drought. Duchesse d'Angoulême, Beurré Hardy, Glon Morceau, Beurré Superfin, Autumn Bergamot, and Marie Louise are the best. Peaches are good and of fine colour where watered in dry weather. Morello Cherries are the heaviest crop for many years. There was a good promise for heavy crops of Plums in early spring. January and February were very warm, but the following two months were very cold, which checked the sap and destroyed the blossom. There are fair crops on walls, but none on pyramids.—W. OSBORNE.

SUPPLEMENTARY.

Coolhurst, Horsham, Sussex.—Fruit crops generally are not what they were expected to be in the early part of the season. No doubt there are exceptions according to soil and situation. Every kind of fruit tree flowered in such abundance that the idea formed then was that crops would be unusually heavy. Strawberries have been highly satisfactory, the fruit being large, finely coloured and abundantly produced on Sir Joseph Paxton, Vicomtesse Héricart de Thury, President, and Royal Sovereign. These varieties under thorough cultivation of the soil never fail to crop well under all conditions of weather. After growing many kinds together for some years, close observation of the habits of the plants in growth and fruiting qualities has led to mostly all being discarded except the four named above, and the poorest flavoured of these is Royal Sovereign, which being light in colour, too, is never likely to be a popular dessert Strawberry in private establishments. If I were limited to one Strawberry, Vicomtesse Héricart de Thury would be my choice. The berries are in all respects large and of fine flavour from the first two pullings, and then the third is of an excellent size for preserving. No other Strawberry that I know parts so easily from the husk, so that there is no bruising of the berries, and consequently all the juice is retained. In its growth it is most robust and free. It stands drought better than any other, so that in every sense it is pre-eminently in the front rank. Its suitability for forcing is so well known, that no remark in its favour in that respect is necessary. The other three named are equally suitable for forcing, only Royal Sovereign does not travel well, being softer than the others. Sir Joseph Paxton is the finest dessert Strawberry in cultivation when grown in highly cultivated land made at least 2 feet deep and well enriched to ensure fine healthy plants that will produce fruit of the finest form and colour. Empress of India is an excellent dessert Strawberry, and is a shade later than the preceding kind. It is an excellent grower and stands drought well. Black and Red Currants have been excellent crops of fine fruit. Raspberries, too, have been good, but these all vary according to how they are cultivated. They all need deep soil and good surface mulchings to retain the winter's moisture, and if they all can be grown on cool north borders, so much the better. Gooseberries have been very plentiful and of fine quality, the trees all being healthy and quite free from caterpillars. Since I have adopted the plan of going over all the trees in the early part of the season with the engine and soap-suds, I have had no trouble from these insects. The same course was adopted with the Currant trees, with equally good results. Morello Cherries were a fair crop. Plums are poor; only Pond's Seedling, Jefferson's, Belgian Purple, and Coe's Golden Drop are the varieties that are bearing anything like a crop. Pears on the whole are thin, too, there being only good crops of Williams' Bon Chrétien, Beurré Superfin, Souvenir du Congrès, Louise Bonne of Jersey, Beurré Hardy, Conseiller

de la Cour, and a few others. Apples here are, on the whole, cropping well, particularly Claygate, Court Pendu Plat, Cox's Orange Pippin, Dumelow's Seedling, Grange's Pearmain, King of the Pippins, Lady Sudeley, Lane's Prince Albert, Lord Suffield, Mannington Pearmain, Mother (American), Peasgood's Nonsuch, Potts' Seedling, Ribston Pippin, Rosemary Russet, The Queen, Blenheim Orange, and several others in the orchard that are unnamed, possibly of local origin. All flowered magnificently, and the inference was that all would have borne alike. In the surrounding district Apples vary very much. Filberts are good; Figs fair; Mulberries plentiful and full sized; Walnuts very thin.

Vegetables had rather a trying season, May and June being cold months, with almost perpetual north-east winds, that are detrimental to vegetation in a young state, so that growth was slow and backward, and since the middle of July there have been for the most part excessive heat and consequent severe drought, so that vegetables on thin land have suffered considerably in their growth, and if one thing more than another stands out prominently in that respect it is Cauliflowers, which unquestionably are the most thirsty things grown. Early spring Cabbages were good, and now Rosette Coleworts: Brussels Sprouts are full-sized in growth and very promising for a fine yield of sprouts. Onions are excellent, there being little mildew and no maggots: Carrots are not so good as could be desired, the severe

Rhododhamnus Chamreistus. Engraved for THE GARDEN from a photograph of a plant in the Royal Gardens, Kew, by Mr. J. Gregory, Canterbury Road, Croydon.

drought being against them: Runner and French Beans are very plentiful; Peas on the whole are good for the season. Potatoes, as far as lifted, have been excellent in quality and very abundant: Early Puritan, Beauty of Hebron, Snowball, Sutton's Seedling, and many others grown here are so close in point of quality, form, and cropping that there really is little more than name to distinguish the one from the other. I always grow Potatoes on ground that was manured well the previous year, only at planting time giving the ground a good dressing of burned ashes. That is enough to ensure sound, dry, disease-resisting tubers.—A. KEMP.

Stoke Bruerne Park, Towcester.—Fruit has this year been very satisfactory, taking into account the short time the trees have been planted (this being their third summer). Apples are plentiful and had to be thinned on some trees. Such sorts as Emperor Alexander, Bismarck, Queen, Bramley's Seedling and Lane's Prince Albert are carrying heavy crops, so are Cox's Orange, Ribston Pippin and King of the Pippins. The best early sort with me is Beauty of Bath: Irish Peach also does well. Mr. Gladstone has a heavy crop, but I do not think much of it, as it is too soft and mealy. Pears are a fair crop. Strawberries have been excellent, Royal Sovereign

being the favourite. I tried Monarch and Leader, but I would not advise anyone to plant them. Most of the plants of Monarch were fruitless. The fruit is very good for size and colour, but deficient in flavour. Leader had more fruit than Monarch, and taken altogether did better, but nothing to be compared to Royal Sovereign. Raspberries, Gooseberries and Currants (Red, White and Black) carried heavy crops: Morello Cherries are also cropping well. Plums, Peaches, Apricots and Nectarines are very scarce.

Vegetables with me this year have been remarkably good, although there was very cold weather during May and early in June. Potatoes have been very good, Sutton's Ninety-fold doing well. Harbinger was a heavy crop, but Ring-leader was preferred at table. It is not such a heavy cropper with me. Later kinds looked well until recently, when disease appeared. Cauliflowers have never been better, Magnum Bonum and Autumn Mammoth producing fine heads. Onions are quite up to their usual standard; winter ones were a grand crop, the best variety with me being Giant Rocca. Those sown under glass in January and planted out in April are very good, and I find that if these plants are put in with a dibber about 6 inches from plant to plant and about 1 foot from row to row, I can get a heavier crop than by sowing in drills in the usual way. Of course, if larger bulbs are desired, you must allow more room for the plants and manure the ground well. Cabbage, Broad Beans, early Carrots, summer Beet, Turnips and early Celery have done well. Runner and French Beans were long in coming in, but are now carrying heavy crops. Broccoli and Kale are healthy, and are now growing fast.—J. DYMCK.

TREES AND SHRUBS.

RHODOTHAMNUS CHAMREISTUS AT KEW.

The engraving that appears on this page is a charming representation of this beautiful alpine shrub in flower in the rockery at Kew last spring. The species is one better known among gardeners by repute perhaps than by actual experience, for it is one of the most uncommon of ericaceous plants in gardens and one of the most difficult to establish. It was originally introduced to this country in 1786, in which year Messrs. Loddiges, the well-known nurserymen of Hackney, had seeds sent to them from the mountains of Carniola, in Austria. It is by no means rare in a wild state, being found in the Tyrol (often in large patches) as well as in Carniola. Loddiges raised and flowered it from seed, but a similar success appears to have been very seldom attained since. As I have seen it, it has been imported in the shape of living plants, which consist as a rule of long, straggling stems not well furnished with either roots or foliage. It was in this condition that the plant now figured reached Kew five or six years ago, but, more fortunate than several others, it managed to survive, and, once established, it has increased in size and flowered in greater beauty every year since. In cultivating this plant, the factors most important to success appear to be full exposure of the foliage to sunlight, combined with cool, uniformly moist conditions at the root. This has been secured at Kew by planting it in a sunny position in a crevice or small pocket between the stones, which keep the roots permanently moist and protected from the hot sun that the leaves enjoy. The compost should consist mainly of good loam, to which a small proportion of peat may be added, and which should be free from calcareous matter.

The genus *Rhododhamnus* is comprised in this little plant, which is a dwarf evergreen

shrub of almost procumbent habit, and keeps as a rule below 1 foot in height. Its leaves are ovate, from a quarter of an inch to half an inch long, thickly clustered on the twigs, and have the margins set with slender hairs. It flowers towards the end of April and the beginning of May, and produces its blossoms in clusters at the ends of the shoots. From two to four flowers are in the cluster, and each is about 1½ inches in diameter, the free portions of the petals fully expanded, as the engraving shows. The colour is a pale clear pink with a ring of a deeper shade in the centre. A feature of the flower also is the long stamens.

This plant was originally called *Rhododendron Chamæcistus* by Linnaeus, a name that is often applied to it still. It is, however, more nearly related to the *Ledums* and *Kalmias* than the *Rhododendrons*. W. J. B.

The claret-coloured Vine is not planted nearly so much as it deserves. At one end of the mansion at Gunton Park, that was burnt some few years since, a plant of this Vine is now 20 feet high. The foliage is very handsome, with that purple colour which renders it so attractive, and which will deepen as the autumn advances. The leaves do not fall nearly so quickly as in the case of *Vitis inconstans*, for instance, and for this reason it is all the more desirable.—E. M.

Tecoma radicans.—At this time of year few things are more beautiful than a large plant of this fine climber against a south wall or trellis. The growth is very free, and the fine fulvous red blossoms show up grandly against the deep green foliage and stems. To grow the plant and flower it at its best, a sheltered place is necessary, yet a place where plenty of light reaches the plant from every side, this ensuring a thorough ripening of the wood. Being a very vigorous grower, the border for it should be rich and well drained, and the surface must be mulched if any fear of drought exists. But where it has the run of a border of any extent the roots are almost sure to ramble about until they find something to suit them. The plants then virtually look after themselves. Pruning consists in cutting out as much as is necessary every season of the wood that has flowered, and the less of this the better where there is room for it to extend. A fine plant will produce an immense amount of bloom when thus left alone, each of the shoots being terminated by one of the large panicles of flower. Its propagation is easy, the present being a good time to strike cuttings of the flowerless shoots where only about half ripened. It may also be grown from layers and root cuttings.

Sophora japonica.—During this hot and dry season, when, unless in especially favoured districts, nearly all our deciduous trees present a more or less sere and withered appearance, this *Sophora* still retains its deep rich green hue, which is at once sufficient to direct attention to it, and when in addition it is laden with numerous racemes of cream-coloured blossoms, it is then particularly noticeable, standing out as it does as the last of our flowering trees. This *Sophora* forms, as a rule, a dense, round-headed specimen, that when in an open situation frequently branches at but a little height from the ground. While the rich tint of the foliage is so noticeable when in leaf, it is also conspicuous during the winter, as the smooth bark of the young shoots is of a deep green colour, which renders it very distinct. In its young state this *Sophora* makes by far the greatest headway in a good free soil, as the roots are more deeply descending than those of many other subjects. This very circumstance enables it to resist drought well even in dry, gravelly soils, as the roots penetrate to a considerable depth in search of moisture. The same feature can be observed in many other leguminous trees and shrubs, which may be seen flourishing in situations where more surface-rooting subjects suffer greatly. The *Sophora* was intro-

duced into this country in 1763, and, as implied by the specific name of *japonica*, it was always regarded as a native of Japan till Professor Sargent visited that country in the autumn of 1892, and gave us the result of his observations in "The Forest Flora of Japan." He says that the *Sophora* does not occur in that country in a wild state, but is one of the many subjects brought into the empire from China and Corea, and cultivated to a greater or less extent by the Japanese. Apart from individual differences, there are a couple of well marked varieties, which must, however, be regarded more in the light of curiosities than of high ornamental value. They are variegata (a poor thing) and pendula, one of the most pronounced of our weeping trees. Apart from its uncommon appearance when grafted standard high, it is very curious when creeping along the ground.—H. P.

DEUTZIA CORYMBIFLORA.

We owe the introduction of this *Deutzia* into France to M. Maurice de Vilmorin, who received in 1895 seed from Abbé Farges, of the Foreign Missions. These seeds came from Western Se-Tchuen (China). They germinated freely and some of the plants planted out produced flower-buds in November the same year. They flowered in April, 1896, with M. Boucher in Paris, to whom they were entrusted, who the following year, on April 7, 1897, was able to present a plant in flower under name *Deutzia corymbosa* to the National Horticultural Society of France. After pointing out the origin of the new shrub, M. de Vilmorin set forth his reasons for the adoption of the specific name *corymbosa* :—

"The drawing given in the "Laubholzkunde" of Dippel for *Deutzia corymbosa* (Royle) (after Robert Brown) appeared applicable to this plant. The "Index Kewensis" identified *D. corymbosa* (R. Brown) with *D. parviflora* (Bunge). M. Franchet, of the Muséum, also ascribed to *D. parviflora* (Bunge) the flower branches which were submitted to him by M. de Vilmorin. M. Maurice de Vilmorin had remarked a decided difference in precocity at Barres, in 1896, between the two plants, not to speak of several characteristics, and M. Lemoine Père told him without any hesitation that the plants of which he showed them dried specimens were not *D. parviflora*. The handbook of the arboretum at Kew, later by five or six years than the "Index Kewensis," does not give the two species *D. parviflora* (Bunge) and *D. corymbosa* (R. Brown) as synonymous. The probability, therefore, is that the differences between them are sufficient to proclaim them as distinct species, and that M. Boucher's plant is *D. corymbosa* (R. Brown). On referring to the description of *D. corymbosa* (R. Brown) it is seen that this plant has, like *D. parviflora* (Bunge), round petals, and that it is distinguished by rather larger flowers and by the petals being smooth, whilst those of *D. parviflora* (Bunge) are hairy. To us these characteristics are at most sufficient to make of *D. corymbosa* (R. Brown) a simple variety of *D. parviflora* (Bunge). There is nothing, on the other hand, which permits of identifying it with our plant. It is also impossible to identify it with *D. corymbosa* (Lindley), which is none other than *D. staminea* (R. Brown), a native of the Himalayas and East Indies, with colourless leaf, very late bloom, and insufficient hardiness for our climate. Still less is it a question of identifying it with *D. corymbosa* (Hort.), which is simply a form of *Philadelphus inodorus* (L.).

To conclude, the name *corymbosa*, whether of Robert Brown, Lindley, or the horticulturists, is inapplicable to our plant. No other

species described until our day can be identified with it. The three most allied to it are: (1) *D. staminea* (R. Brown). We have seen how this is distinct from it, and, moreover, a single glance is sufficient to take in the differences between them. (2) *D. Fargesii* (Franchet), of Eastern Se-Tchuen, which differs from ours by the smallness of its stature, thick leaves smooth on both sides, and blunt petals. (3) *D. setchuensis* (Franchet), of Eastern Se-Tchuen.

M. Franchet, after finding points of resemblance between *D. corymbosa* and *D. parviflora* (Bunge), ended by identifying it with *D. setchuensis* (Franchet). But the description given by himself to this last species does not allow of any such identification; in fact he attributes to it a small leaf and a paucity of inflorescence, petals double the length of the stamens, furnished extensively with hairs and starred with brown centres, characteristics none of which belong to our plant. We consider ourselves authorised to give it the name which appears at the head of this article, *D. corymbiflora*, a specific term not yet appropriated in the nomenclature of the *Deutzia*, whilst sufficiently recalling the denomination under which the plant was first presented to the public.

The appearance of the flowers is that of *Solanum jasminoides*, only smaller. Their number is so great, that they cover the shrub like a dome of snow for more than a month. The normal blooming begins in the second fortnight of June, when the flowers of *D. crenata* and its numerous varieties are about to leave us, and, thanks to the wealth of buds opening in succession, the bloom at the end of July is as abundant and as fresh as at the beginning. It happens often indeed that the year's stems terminate in September with new inflorescences, without prejudice to the bloom of the succeeding year. Since its introduction this shrub has stood perfectly in the open the rigours of our winters. It is, therefore, a novelty to be recommended, and which produces the finest effect, whether isolated in the centre of lawns or arranged in small groups on the borders of shrubberies.—E. LEMOINE, in *Revue Horticole*.

VERONICAS.

In the milder districts of England the *Veronicas* form a very beautiful class of outdoor shrubs, whose value is enhanced by the fact that their flowering season extends well on into the autumn, at which time plants of this class in bloom are by no means numerous. They are, as a rule, frequently cut about in the London district, and to see them at their best one must go to the south or west of England, where, especially in the neighbourhood of the sea, they are often particularly fine. Apart from their value as outdoor shrubs, they are also very useful for the decoration of the greenhouse or conservatory during the autumn and winter months, either grown altogether in pots, or planted out during the summer and lifted towards the end of August. One feature that stands them in good stead for this latter mode of treatment is the fact that they form quite a dense mass of fibrous roots and very quickly recover from the check of removal, continuing to flower as if they had been allowed to remain undisturbed. Of course the plants must be kept rather close and shaded with occasional syringing till the roots are again active, which will not take many days. Even comparatively small plants of *Veronicas*, if planted out as soon as sharp frosts are over, will by autumn form neat bushes bristling with flowers, whose beauty (if allowed to remain undisturbed) will be limited only by severe weather. This refers, of course, to districts where they are not absolutely hardy, and not to localities where they pass unscathed through the winter. They all strike

root readily from cuttings and grow away freely afterwards. Some of the varieties are brought into Covent Garden Market in large quantities, and form very familiar objects on the costermongers' barrows in the streets of London, while they may be seen struggling for existence on many a window-sill and balcony. One variety—*V. Andersoni* variegata—whose shining leaves are freely variegated with white, has long been known, but is not so popular as formerly, when rows of one subject were so generally seen. A smaller growing compact variety with variegated leaves—*Silver Star*—received an award of merit last autumn. Another variety honoured the same as the preceding is *La Seduisante*, whose long spikes of rich reddish purple blossoms are very showy. *Purple King*, a compact form with a profusion of purple flowers, was raised and distributed by Messrs. Veitch a few years ago, and has since become very popular. There is quite a long list of garden varieties of these shrubby *Veronicas*, most of which are of French origin. One is occasionally asked for the best white-flowered form belonging to this section, and of those I have met with the first place would be given to *Reine des Blanches*, which was distributed by M. Heste in 1891. Besides this last-named gentleman, another raiser of these *Veronicas* is M. Simon Délaux, of St. Martin du Touch, so well known from his connection with the *Chrysanthemum*. The above notes on the *Veronicas* refer of course to the free-growing varieties—hybrids of *V. Andersoni*, *V. salicifolia*, *V. decussata*, and others of this class, and not to the curious little shrubby forms, the members of which are more suited for rockwork than for other purposes. T.

NOTES & QUESTIONS.—TREES & SHRUBS.

Ivy and *Ceanothus azureus* growing together against a south wall I lately saw, and was much struck with the combination. The close-growing Ivy made a capital background for the dark blue flowers of this *Ceanothus*.—E. M.

The white Elderberry. While the black variety of Elderberry is found growing in almost every part of the country, how seldom is the white variety met with. The only two places that I know of its growing are Highlands Park, Chelmsford, and Thorndon Hall, Brentwood, both in Essex. It is very vigorous in growth and bears freely, the berries being rather larger than those of the dark variety. It makes excellent wine. Even where the fruit is not put to any use the tree is worth growing for ornament.—J. C.

A GARDEN STREAMLET.

WATER in the garden is valuable from the artistic point of view, since it permits the grouping around its verge of moisture-loving plants, many of them of noble form, and others the embodiment of grace, that in drier positions would fail to attain their full proportions, while their outlines are nowhere shown off to such advantage as when rising from the water's edge. Many beautiful pictures are formed by lakelets fringed with the giant leaves of the Gunneras, with the tall, pennoned shafts of Bamboos or Arundo, and with the whiteness of the Arum's spathes, while on the placid surface the Water Lilies float; but while such a scene must ever hold a charm for the lover of tranquil, natural beauty, the running stream, breaking here and there into falls, eddying swiftly round a bend, or lying seemingly asleep in the shady pool, where on the further side, beneath overhanging boughs, the foam-flecks from the cascade above circle slowly, is a still more delightful adjunct to the pleasure ground. It charms one with its ever-changing moods, now murmuring softly as it ripples merrily over its uneven bed in the bright sunshine, now voicing a deeper note as it plunges down a rocky fall, now silent as it glides softly

into the shadow, where the great Ferns sweep their curving fronds and the dragon-fly makes a momentary brilliance. Happy are those whose garden ground contains such a stream—a stream which should be a delight through all the changing seasons of the year. In the early spring there are the Snowdrops, Scillas, Anemones, Primroses, Snowflakes, and early Narcissi to spangle its banks, later on the Poet's Daffodils, rising from an azure carpet of Forget-me-not, then come the Irises and Spiræas, Lilies, and tall Campanulas, Mimulus, scarlet

is necessary. Sometimes only slight alterations are needful, but occasionally circumstances compel an entirely rearrangement of levels and conformation. It is in the latter case and where water is laid on to counterfeit the effects of a natural stream that the difference between artistically designed and artificial surroundings become conspicuously apparent. One can, unfortunately, call to mind numerous instances where falls and cascades, which should have been things of beauty, have been rendered offensive to the sight by reason of the crude

A rocky stream in a garden within three miles of New Street Station, Birmingham. From a photograph sent by the late Mr. James Pullham.

Lobelias, and a host of other flowers that will brighten its course during spring and summer, while in the late autumn the vivid crimson of the Winter Flag and the scented lavender blooms of *Iris stylosa* will not permit its environs to become colourless.

It does not often happen that natural streams possessing the diverse charms already alluded to are to be found within the confines of the garden grounds. In most cases some modification of the existing course of the running water

stonework within which they are confined and tortured out of all semblance to Nature. A glaring case of such misapplied ingenuity is in my mind's eye as I write. In this instance it was determined to lead a small volume of water to the face of an almost precipitous cliff, at the foot of which a narrow pool had already been constructed. Although a gush of water, apparently from the side of the rock, might have appeared slightly incongruous, it would, had it been allowed to find its own way down the

20 feet or so that intervened between its points of appearance and destination, have been little open to adverse comment after the cliff had become discoloured by its flow. Instead, however, of this leave-alone policy being pursued, a more ambitious and infinitely more aggressive design was conceived and carried out, artificial rockwork being built up the face of the cliff with stones absolutely unlike the rock in colour and texture, the most conspicuous positions being occupied by glistening spar. At the point of its egress the water, instead of trickling unostentatiously out of the rock, flowed in an even semi-circle over a lip of cement which protruded some inches beyond the face of the cliff, falling thence into the cemented course prepared for it, which zig-zagged aimlessly amongst the piled-up stones, escaping eventually into an oval cement basin, whence it brimmed over into the pool below. Thus was a feature that might have added materially to the charms of the garden rendered an eyesore by reason of its intentionally artificial construction. The constructor of an artificial stream-garden should be imbued with a desire to work with, not against, Nature. Water should fall naturally over stratified rocks, as in the accompanying illustration, which affords ample proof that artistic and natural effect may be attained even by artificial means. There should be a reason for every curve of the stream, for every rock that bars its way. A natural obstruction diverts the even flow of the stream, which either finds its way through a tract offering less resistance or, failing this, surmounts the obstacle, deepening into a pool above and falling in a cascade to a lower level on the further side. In the picture before us we see in the distance a vista through which the water flows placidly along a higher level; as it nears the half-submerged stones at the head of the fall it whitens into foam at the contact, and, passing on, leaps from ledge to ledge, till, shrouded by flag leaves, it finds rest again in the still pool on whose surface the Ferns and overshadowing boughs are mirrored.

S. W. F.

AUGUST IN SOUTH DEVON.

THE rainfall for the past month has been below the average, amounting to but 2.10 inches on thirteen days, against an average fall for August of 2.78 inches, while during the same month of 1897 3.31 inches of rain fell on twenty days. The rainfall for the past eight months of the year shows a great decrease compared with the average fall for the period and for that recorded during the same months of last year, the figures being 13.16 inches of rain on ninety days, from January 1 to August 31 in the present year, 23.84 inches on 117 days during the same period of 1897, and an average fall for that time of 20.41 inches. We are, therefore, at present 7.25 inches behind our average rainfall for the year and 10.64 inches behind that of last year. The greatest fall of the month was 1.14 inches on the 18th, which fell within the space of about three hours. Of sunshine we have had 193 hours 35 minutes, which is a trifle in excess of the average for the month of 192 hours 45 minutes, but much below the record for August, 1897, which was 217 hours 35 minutes. During the past eight months 1307 hours 25 minutes of sunshine have been registered compared with 1339 hours in the same months of 1897, and an average for the period of 1321 hours 45 minutes. The mean temperature of the month has been high, reaching 63.6° against 61.2° in August, 1897, and an average for the month of 61.4°. The highest sun temperature has been 124.2° and the highest screen reading 78.9° on the 16th, which is the highest experienced during the year, and higher than any screen reading of 1897, in which year

the highest, 78.7°, was registered during the month of July. The lowest screen temperature was 48.2° on the 9th, and the lowest grass reading 45.2° on the same date. The month has been fairly calm, the total horizontal movement of the wind having been 6286 miles against 7977 miles in August, 1897. The highest daily record was 421 miles on the 30th, while the greatest hourly speed was reached between the hours of 8 and 9 p.m. on the same date, when a rate of 30 miles per hour was recorded. Ozone has been remarkably absent from the atmosphere, barely 50 per cent. of the possible having been present.

In spite of the dry weather experienced during the past two months there is as yet no sign of the sere and yellow leaf of autumn. The Chestnut hard by, which is always the first of the woodland to shift its verdant mantle for a robe of crimson and gold, is still darkly green; whereas in former years its ruddy glow was gleaming down the lane ere August had waned, and though the absence of insect life in the cooling upper air, from which the swifts draw their food supplies, has caused them to leave for sunnier climes, the swallows and martins, whose prey is found in the warmer layers of atmosphere that more closely envelope the earth's surface, have as yet shown no disposition to collect in companies on the house-tops and essay sudden, brief flights preparatory to taking a prolonged farewell of our northern shores; indeed, some of the young martins are but learning the use of their pinions. This tardy coming of autumn is a welcome reprieve. For a little longer we may ignore the presence on the threshold of the forerunner of winter, but it can be now but a question of days before the gleam of her bright mantle will become visible on woodland and hedgerow.

In the garden *Achillea ptarmica* fl.-pl. The Pearl has continued to flower abundantly, and the Monkshood (*Aconitum Napellus*) has borne a second crop of blue bloom-spires. In a corner of the wild garden the giant *Acanthus mollis* and the dwarfer-growing *A. spinosus* have perfected their tall flower-rods, those of the former reaching a height of over 7 feet. Close to these, near an old dipping-well, *Gunnera scabra* spreads abroad its rugged leaves, and Siebold's Plantain Lily shows its cordate, blue-green foliage, while strong plants of *Canna Ehmanni iridiflora*, 5 feet in height, display many a pendent rose-lake flower-cluster above the smoothness of their Musa-like leaves. There are few *Cannas* that can compare for grace of form and delicacy of colouring with this, which is quite hardy in light soil in the south-west. The light blue of *Agathaea celestis* has a charming effect in the garden, especially when associated with some more vivid colour. In sheltered situations this will live through the winter, and in a particularly favoured garden I have seen a plant, nearly 3 feet through, blossoming almost in mid-winter. The bright orange of *Alstroemeria aurantiaca* was visible in the borders well into the month, but the more tenderly coloured hybrid forms were flowerless before the commencement of August. Sweet Alyssum, with its honeyed perfume, attracted the hive-bees from far and near, and the white *Antirrhinum*s, where the seeding spikes have been removed, have formed attractive breadths of colour. *Anemone japonica alba Honorine Jobert*, over 5 feet in height, has been exceedingly beautiful, and if anything more floriferous than usual, not commencing in mid-July, as it did last year, but expanding its earliest blossoms on the opening day of August. Of the perennial *Asters*, or *Starworts*, *A. Amellus bessarabicus* with its large purple, golden-centred flowers has been conspicuous, and towards the end of the month the white *Aster Novi-Belgii* Harpur-Crewe commenced to blossom. The Plume Poppy (*Boconia cordata*) was a striking sight early in the month with its tall spires of inflorescence of ivory-white and burnt-almond colour and its deeply-cut, glaucous foliage, whose reverse showed silver-grey when stirred by the wind. In deep and moist soil this subject will attain a height of 8 feet, and is especially adapted for positions where its attractions can be thrown

into high relief by a background of evergreens. The *Belladonna Lilies* have already commenced their display, their bright pink-margined petals being well set off by the chocolate-coloured flower-stems. The variety known as *blanda*, paler in tint and with petals more reflexed, appears as hardy as the type. The tuberous *Begonias* have been a blaze of gorgeous colour which has week by week increased in volume. Of the *Bellflowers*, the tall *Chimney Campanula* (*C. pyramidalis*) has reared aloft its stately spires of bloom, purple, white, and mauve, while the different forms of *C. carpatica* have also been in flower. Many a border has been bright with the large-flowered *Cannas* with their vivid scarlets and yellows, and the *Marguerite Carnations* are blossoming bravely in a number of gardens. The slender bloom-spires of *Chelone barbata*, loosely set with hanging tubular blossoms of bright scarlet, have been very attractive, and *Chrysanthemum maximum* has produced its large Daisy-like flowers in profusion, the type, however, being far inferior to the variety known under the name of *C. m. grandiflorum*, a rather earlier blossomer, whose flowers are larger and whose growth is dwarfer and less coarse. The first pale purple blooms of the autumn *Crocus* (*Colchicum autumnale*) are already in evidence, and *Cosmos bipinnatus* is expanding blossoms on plants sown in the open ground. The white variety is a charming flower, its delicately-cut *Nigella*-like foliage rendering it particularly pleasing. *Coreopsis grandiflora* still maintains the brilliance of its golden yellow, but after its extended flowering it naturally shows a disposition to reduce both the number and the size of its blossoms. If these are never allowed to wither on the plant it is astonishing for how lengthened a period it will continue to bloom. Later sown batches of the blue *Cornflower* provide pretty breadths of colour here and there, and in a sheltered garden a bed of *Crinum* capense has been crowned with several massive umbels of flesh-pink flowers. *Cypella Herberti* is evidently weaker than the preceding year, as only six blossoms have expanded against five times as many in 1897.

It is in August and September that the *Dahlias* are at their best, and none are so admired as those possessing the true Cactus shape of *Juarezii*. Many of the most perfectly shaped and coloured flowers, however, are not sufficiently thrown up from the foliage to give an ornamental effect to the plant unless the latter be judiciously thinned. Of scarlets and crimsons there is nothing in form and hue of flower to oust the first introduced of the class, *Juarezii*. Other handsome flowers of this and allied shades are *Gloriosa*, *Harry Strudwick*, *J. E. Frewen*, *Mayor Haskins*, *Miss Annie Jones*, *Mrs. A. Beck*, *Professor Baldwin* and *Starfish*; good yellows are *Blanche Keith*, *Daffodil*, *Eileen Palissier*, *John H. Roach* and *Lady Penzance*; of maroons, *Matchless* and *Night* are excellent; while of different shades of salmon, *Alfred Vasey*, *Fusilier*, *Mrs. Wilson Noble* and *Tillie* are charming flowers. *Beauty of Arundel* and *Cycle* are of a glowing lake tint, the latter being of better form, while *Bridesmaid* and *Delicata* are of delightfully blended pink and sulphur, and *Island Queen*, a pretty pink suffused with lavender. *Cactus Dahlias* are weakest in the white varieties, of which the new *Keynes' White* gives promise of being the best; the pick of the other whites, *Mrs. A. Peart* and *Mrs. F. Fell*, are far from being of ideal Cactus form. Here and there side spikes of the blue *Delphiniums* are still bright, and the brilliant crimson of *Dianthus Napoleon III.* makes a spot of colour in the foreground of the border, while a few yellow stars of *Doronicum plantagineum excelsum* Harpur-Crewe mark the clumps that in the spring were sheets of golden bloom. The handsome *Globe Thistle* (*Echinops Ritro*) has borne aloft its blue spheres, and *Erigeron speciosus*, after a lengthened flowering period, still produces its lavender-blue, yellow-centred star flowers, while the Mexican Daisy (*Erigeron mucronatus*) is blossoming as profusely as in mid-June. The Coral Tree (*Erythrina crista-galli*) has been especially

effective during the past month, large plants of it growing to a height of about 6 feet in front of a wall and bearing long racemes of bright crimson flowers, some of them almost 3 feet in length. These spikes are handsome for indoor decoration, but discretion has to be exercised in cutting them, as both stems and leaves are furnished with sharp, curved thorns, which are capable of tearing the flesh cruelly. In cottage gardens *Fuchsia Riccartoni*, grown into tree size, is studded thickly with innumerable flowers of glowing crimson. *Gaillardias* are still bright with their red and gold, and in the early part of the month the Goat's Rues (*Galega*) were still very decorative, the Pea-like blossoms lasting well in the hot weather. The tall Cape Hyacinths (*Galtonia candicans*), with their tiers of loosely-poised ivory bells, are most effective in the garden, especially when associated with brightly-coloured flowers, such as *Gladiolus brenehleyensis* or *Salvia patens*. On sunny banks the *Gazania's* orange blazes, and here and there a spot of scarlet shows where *Geum coccineum* is still blooming. In many a garden sheaves of the scarlet *Gladiolus brenehleyensis* have created a brilliant effect, while the less pronounced tints of *G. Lemoini*, with their pale sulphurs and buffs and blotches of chestnut and maroon, have well repaid closer inspection. The delicate flower-lace of *Gypsophila paniculata* has foamed over the margins of borders in billows of transparent grey. It is as charming in the garden as it is for indoor decoration, its contour and suggestion of subdued colour rendering it unique in the garden, while it is indispensable for arrangement with cut flowers of almost every description, retaining, indeed, much of its lightness and grace long after the sap has dried in its hair-fine stems. As the month was waning, the Golden Rods (*Solidago ambigua*) began to show their yellow-sprayed bloom heads in odd corners of the cottage gardens, where many a stately Hollyhock reared their massive spires of double and single blossoms against the white-washed walls.

The perennial Sunflowers have spread their gold over the garden, *Helianthus multiflorus* and *H. m. fl.-pl. Soleil d'Or* being the first to attain perfection, followed later in the month by *H. latiflorus* and *H. rigidus* Miss Mellish, while *H. giganteus* began to show a fringe of pale gold where its lofty growths hid the turning of the lane ere August had departed. In sheltered spots plants of *Heliotrope* that had survived the winter in the open had made fine clumps odorous with blossom. In the early part of the month the variegated Day Lily (*Hemerocallis Kwanso fl.-pl. fol. var.*) was still producing its orange-buff blooms, while the great *Hydrangea* bushes daily enlarged their orbed flower-heads, here light-blue around the boles of giant Elms, here flesh colour and pink at the edge of the shrubbery. *Lavatera trimestris*, where it has not been allowed to run to seed, has remained decorative in the garden, while for floral arrangement the satin-pink, crimson, and white flowers are most attractive, lasting well in water if cut before fully expanded. Of Lilies, the scarlet Turk's-cap (*L. chalcodoneum*) ushered in the month with its glorious colouring, more vivid than that of any other Lily. *L. canadense*, *L. pardalinum*, and *L. superbum* also blossomed, but not so strongly as in the preceding year, while *L. Humboldti* was far finer, throwing up 6 feet-high flower-stems plentifully set with orange-yellow, lake-spotted blooms. *L. auratum* flowered well in many instances, some in a neighbouring garden having attained a height of between 7 feet and 8 feet, while in my own some imported bulbs have bloomed fairly for the sixth year in succession. After the rest of the Lilies had passed the zenith of their beauty, *L. speciosum* was for a short space belle of the Lily bed, soon to give place to *L. tigrinum splendens* and *L. t. Fortunei*, the latter being the more satisfactory with me and attaining a height of about 7 feet. *Lobelia cardinalis* has been and still is blooming grandly, its vermilion flower-spikes, 3 feet and 4 feet high, rising out of a mass of *Gentian-blue* *Salvia patens*, an opulence of colour effective both at a distance and

near at hand. The *Lobelia* plants have now been undisturbed, with the exception of occasional late autumn division, for six years, and have never been afforded the slightest protection during the coldest winters. They are growing in heavy soil in close proximity to water and have endured 20° of frost with impunity. *L. rosea* is also blossoming hard by. In positions slightly screened from the sun, the scarlet flower-heads of *Lychnis chalcodonea* were noticeable early in the month, while in waterside gardens the rosy *Loosestrife* (*Lythrum*) was to be seen blooming. At the verge of shrubberies the rigid flower-spikes of the *Kniphofias* blaze against the dark background, and the *Montbretias* brighten the garden with their sheaves of graceful orange-scarlet flower-scapes. The crimson *Bergamot* (*Monarda didyma*) and its white variety were both in bloom during the early days of the month, their display being continued by *M. hirta*, while here and there along a shady path a few pendent yellow blossoms of the Welsh Poppy (*Meconopsis cambria*) might be descried throughout the month. The sweet-scented *Tobacco* plant (*Nicotiana affinis*) still perfumes the garden during the gloaming—now, alas, arriving all too quickly—when the giant Evening Primrose (*Oenothera Lamarekiana*) expands its pale yellow blossoms to the twilight dews, and in the morning sunlight *Oxalis floribunda rosea* is still bright.

The Tufted Pansies are still fresh and delightful, but the Poppies have aided little in the floral adornments of August. A few fragile apricot-tinted blossoms have expanded on *Papaver pinnatum*, and here and there the Iceland and Shirley Poppies have yielded bright infrequent flowers. Paris Daisies, yellow and white, have been blossoming freely, the young plants having continued the display so lavishly provided by the old specimens in the early summer, while the Ivy-leaved *Pelargoniums* are still almost as attractive as a month ago. It may not be generally known that the leaves of these plants when bruised emit a distinct Ivy smell. The herbaceous *Phloxes* were bright at the commencement of the month, when *Phygelius capensis* was producing on 4-foot-high stems its brilliant flower-racemes. Towards the close of August the calyces of the Winter Cherries (*Physalis Alkekengi* and *P. Franchetti*) commenced to assume the tint of orange that will grow brighter with the succeeding month. A large plant of *Plumbago capensis* planted against a sheltered cliff, which has passed through the winter in the open uninjured, is covered with its light blue bloom-clusters, while *P. Larpentei* is bearing its more deeply tinted flowers in the rock garden, where *Polygonum capitatum* and *P. vacinifolium* are in bloom. Before the month had waned the tall *Pyrethrum uliginosum* had commenced to expand its slender rayed white stars, while two of the *Coneflowers* (*Rudbeckia Newmani* and *R. purpurea*) both useful autumn plants, were in bloom. The single white *Macartney Rose* has borne many of its simple faintly-scented blossoms, which, though not so large as those of *R. longata*, have the merit of opening until mid-October. The Tea Roses have bloomed well in spite of the drought, and some of the Austrian Briers have given a second flower crop. In some gardens scarlet *Salvias*, which live through a mild winter, have been in flower, *S. coccinea* and *S. fulgens* being the varieties most generally met with. This year's plants of *Scabiosa caucasica* are now producing their charming pale blue flowers, and the Sea Lavender (*Statice latifolia*) has perfected its graceful inflorescence. The great Sunflowers in rows hang their broad brown discs in many a cottage garden, and the Sweet Peas are still gladdening the garden and house with their perfumed, suavely-tinted flowers. Early in the month the *Tigridias* formed a picture of marvellous splendour, the great, widely-spread blossoms, scarlet, lake, white, and yellow, all sumptuously spotted, poised on the bed like gorgeous tropical butterflies. *Tradescantia virginica* has borne its violet blooms, and *Zauschneria californica* a profusion of its bright vermilion flowers, while the single

scarlet *Zinnias* make vivid breadths of colour here and there. Of

SHRUBS AND TREES,

large plants of *Aralia japonica* have produced their Ivy-like flowers, while the feathery flower-plumes of *Aralia spinosa* have had a distinctly charming effect poised above its spreading leaves. When growing this subject, the best result is obtained by keeping it to a single stem until it is at least 12 feet in height, when it may be allowed to branch at will: by this method of treatment a tall, clear stem is obtained, the effect of the tree being almost Palm-like for a year or two after the desired height of stem has been attained, while afterwards the effect produced is far preferable to that provided by specimens allowed to assume bush form at an early age. *Arundo conspicua* is a valuable addition to gardens in the south-west, being practically hardy in that district, and large clumps, with thirty to fifty lissom shafts, tipped with silky, drooping plumes, bending gracefully and swaying with every breath of air, are extremely effective, far more so, indeed, than the stiffer, though more hardy *Pampas* Grass. A sheltered position should be provided for this *Arundo*, for the slender shafts are easily broken by strong winds. *Choisya ternata* has whitened with an autumnal blossoming, and *Cytisus racemosus* is in many cases golden with bloom. Early in the month I observed *Catalpa bignonioides* in flower, while later on (*Clethra arborescens* was bearing its clusters of white bells. *Desfontainia spinosa* has spangled its Holly-like foliage with its scarlet tube flowers, and *Escallonia maerantha* is bearing a second crop of rosy bloom, while the white-flowered *E. montevidensis* has produced its scented flower-spikes, on which on sunny September days the red admiral butterflies love to linger. The Rose of Sharon (*Hibiscus syriacus*) has blossomed profusely, the pure white variety known as *H. s. totus albus* being by far the most ornamental form. The large standard *Magnolia grandiflora* has this year excelled itself in floriferousness. During the past month this tree, which has a height of over 20 feet and a branch-spread of over 30 feet, has borne almost 200 odorous white calices, and as it is now at the zenith of its flower-production, ten to twenty blossoms opening each sunny morning, should reach a total of 500 blooms during the present season. During the month I chanced to see a large standard bush of *Cydonia* (*Pyrus*) *japonica* some 8 feet in height and as much through that was bearing a fine crop of fruit from the size of marbles to that of Walnuts. *Lycyesteria formosa* is bearing its white flowers in their conspicuous purple bracts in quantity on gracefully arching sprays. The Virgin's Bower (*Clematis flammula*) has been prominent amongst the climbers with its myriad ivory-white, richly perfumed stars, and the large purple blossoms of *C. Jackmani* have displayed their velvety richness from trellis and balcony, while the Old Man's Beard (*C. Vitalba*) is festooning tree and crag with its flower-wreaths, to be followed later on by the still more conspicuous seed-vessels that hang like trails of grey smoke from bough and ledge. *Ecremocarpus scaber* has produced its orange-red flower-sprays, and in the hedgerows the Honeysuckle is sweet. *Mina lobata* thrusts its yellow and red flowers through the thick tracery of other creepers, even the *Muhlenbeckia* not being equal to strangling its growth. The white Morning Glory gleams against a fence, but the beauty of the Everlasting Pea was waning while the month was yet young. The Passion Flower's growth is starred with blossoms blue and white, and *Physianthus albens* has been a mass of blossom. *Solanum jasminoides* is week by week attaining a greater perfection of beauty, and is certainly the climber of the south-west *par excellence*: its first blossoms opened in April, and ever since it has been in flower, until at present the house from eaves to ground level is swathed in white bloom-clusters that hang loosely on long, swaying sprays that in places stand out a good 3 feet from the wall and embosom the windows in penthouses of flower

and foliage. *Tropaeolum speciosum* is still flowering sparsely, and the purple berries of its earlier blooms hang from the wall. *T. tuberosum* is just commencing to flower, but *T. Lobbianum* and *T. canariense* have been bright in scarlet and gold throughout the month, and the old *Wistaria*, whose gnarled and sinuous limbs surmount a length of high wall, has dowered August with an unexpected wealth of scented lavender flower tassels. S. W. F.

SOCIETIES AND EXHIBITIONS.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last, the executive committee of this society held a meeting at Carr's Restaurant, Strand, Mr. T. W. Sanders occupying the chair. The usual preliminaries having been disposed of, it was announced by the secretary that the prize-money awarded at the recent September show of early Chrysanthemums, &c., had been paid, and that the following awards to miscellaneous exhibits were made by the arbitration committee, viz. small gold medals to Mr. H. J. Jones and Mr. T. S. Ware; silver-gilt medals to Mr. Green, Mr. Mattock, and Mr. Witty; silver medals to Mr. Chard, Messrs. Cannell, and Mr. F. W. Seale; small silver medals to Mr. Foster and Mr. Wells; and a bronze medal to Mr. T. Williams, all of which awards were confirmed. It was resolved that the catalogue and classification committee hold a meeting during the November show. Mr. Waterer called attention to the prevalence of Chrysanthemum rust, and considered the society ought to take some action in the matter, as it was of vital importance to all growers. Mr. Waterer gave his own experience of the disease, and was followed by several other speakers, whose experience seemed in some cases to vary. Finally, it was resolved that a committee be appointed to engage an expert to lecture on the subject at a conference to be arranged for the evening of the first day of the October show. This course seemed to meet with very general approval. New members were elected, and the Timaru Chrysanthemum Club was admitted in affiliation.

FLORAL COMMITTEE.

A meeting of this committee was held on Monday last at the Royal Aquarium, Mr. T. Bevan presiding. The meeting was a small one, there being but few members present and a very small number of exhibits. *Crimson Pride*, a medium-sized Japanese with flat florets, colour deep crimson, was commended. *Yellow Queen*, a pale yellow sport from *Queen of the Earlies*, was promising, and the committee asked to see it again. Probably one of the best was *Soleil d'Octobre*, a finely-formed Japanese with long drooping florets; colour very pure pale yellow with silvery yellow reverse. No certificates were awarded. Two new cups and tubes were exhibited, one by Mr. Burgin, the other by Mr. Wright.

Burning garden rubbish.—The information afforded by "W. I." under the above heading should prove useful to many others besides "P. B. C. B." I have all kitchen garden refuse, sweepings of roads and walks, pieces of short branches, &c., burnt up in the way described by the aid of Laurel and other shrub trimmings and prunings, as well as hedge trimmings, tree loppings, and also branches and twigs brought down by high winds and gales in the autumn and winter. This is an excellent way of utilising materials of the latter description that in many places are too often allowed to lie about and become an eyesore, and which are practically worthless for any other purpose. The resulting ash when all has been properly burnt in the manner described by "W. I." is of great value in a garden for many purposes, not the least of which is in the dressing of fruit borders and plantations in the winter months. I also use a

certain amount of wood ashes when making new fruit borders, and that it is a good plant food is evidenced by results.—A. W.

The drought.—The drought at present (September 22) shows no signs of breaking. It is proving most disastrous to garden crops generally, particularly to what are usually called green crops. The plague of caterpillars that came like locusts has left nothing but the stumps to mark where the green crops should have been. Dressings of soot, lime and other noxious mixtures had no effect whatever, and the only patches that have pulled through the trying ordeal thus far are small ones, where the owners have been able to handpick their crops daily. Of course this is out of the question where many acres have to be dealt with, consequently many of our market growers have lost heavily by this scourge, which, coming at the end of the long drought, has proved very disastrous to many, as there is no time to get other crops forward before winter comes on. The outlook for winter is very bad indeed. Although so many crops are well-nigh dead from want of rain, it is doubtful if to many things rain will prove of much value. For instance, Strawberry plants are dried up, and if the rain were to start a fresh growth now this would certainly not do any good to next year's flowering. Rhubarb roots lost their leaves and went to rest prematurely, and if rain should come the growth would be from crowns that should remain dormant. The drought will probably hold on until lower temperatures prevail, and there will be little chance of premature growth, for the soil is so dry that a fairly heavy shower dries up in a few hours.—J. G., Gosport.

NOTES OF THE WEEK.

The single China Aster.—We send for your inspection a few blooms of the single China Aster, which has been blooming in our nurseries and forming quite a pretty picture. Each plant forms an elegant bush 15 inches high, covered with flowers which are invaluable for cutting, as they last long in water. The plants continue flowering for a long time.—BARR AND SONS.

Chrysanthemum Soleil d'Octobre.—This variety was well represented recently in a fine trade display, and promises to be one of the most serviceable of the large Japanese flowers for late September and October displays. The colour is a pleasing canary-yellow with a paler reverse; florets of good width, recurring neatly and curling at the tips. It comes good on any bud, and the plant is also very dwarf.

Rudbeckia Newmani.—This showy Cone-flower is made much of at Gunnersbury House, where it is grown in large masses in a border devoted chiefly to hardy things. The plants were somewhat numerous, and, being of uniform size—each plant upwards of 2 feet across—were very effective. They were associated with *Michaelmas Daisies*, both early and late kinds, some of which, as, e.g., *Aster bessarabicus*, were already in flower.

A note from Ireland.—Narrow Water Park is as lovely as ever, and the rock garden is superb. The big *Gunnera manicata* is 36 feet through, 12 feet to 14 feet high, leaf-stalks 9 feet to 10 feet long, leaves 9 feet to 10 feet across. Firefly *Lobelia* is gorgeous here, and *Apera arundinacea* most distinct and graceful. *Bambusa Fortunei aureo-variegata* (*B. auricoma*) is flowering here, and the whole place is most beautiful.—P. W. B.

Helianthus multiflorus maximus.—This is the giant of the perennial Sunflowers of this group, and a noble plant withal by reason of the handsome, well-formed flowers. The great heat, however, coupled with the long-continued drought, has not favoured these this year unless in a few districts. As a rule, however, the early autumn rains come in time to suit this group well. This year the flowers are wanting in size also, as may have been anticipated.

Chryseanthemum Eulalie Morel.—Among the early-flowering kinds this is an especially pleasing flower, though its colour is difficult to describe. It is a mixture of salmon and rose, while the central incurving florets are tipped with gold. By artificial light as well as by day it is equally pleasing, and being dwarf and free should favour its general cul-

ture. The habit also is good, but this season it is not much more than 2 feet high, which is a foot short of its usual height.

Crocus pulchellus.—The beautiful little *Crocus pulchellus* came into bloom here on September 23. Smaller and distinct in every way from the fine *C. speciosus*, which opened the same forenoon, this little gem deserves a sheltered and sunny spot in our gardens. Here I find it one of the most reliable of the autumn Crocuses, and as it seeds freely it is of rapid increase. The flowers vary from almost pure white to pearl blue.—S. ARNOTT, *Carslithorn*, by *Dunfries*.

Delphinium Belladonna.—There is no season of the year in which the lovely flowers of this Larkspur are not welcome, for it is quite unique among its kind, as much for its dwarfness as for the sky-blue of its flowers, and not less so the well-nigh perpetual manner in which they are produced. It is one of the very few Larkspurs that may be employed in small vases, so dainty and beautiful are the frail spikes of flowers. The plant is even now keeping up a nice display that may continue if frost is absent.

Dwarf Chrysanthemums.—Perhaps no varieties of Chrysanthemums can surpass the following trio in their very dwarf, compact habit, which renders them of considerable value for margins or edgings to other kinds, or indeed other plants. The kinds referred to are *Mme. La Petite Marie*, *Mlle. Jolivart*, and *Toreador*. These are pure white, white slightly flushed with delicate lilac, and bronze respectively, and belong to the pompon or hybrid pompon class. This, with comparative earliness, should make them welcome in the garden.

Gynerium argenteum Rendatleri.—The old Pampas Grass is a very fine plant in the garden at the present moment, where its silvery plumes make a pleasing feature in the landscape. It is, however, surpassed by the above-named kind, in which the plumes are more one-sided than in the original form. Its chief value, however, lies in the great freedom of flowering, as also its robust growth. All this was well seen in a fine-flowering piece shown by the Messrs. Veitch at the Royal Horticultural Society on the occasion of the last meeting.

Dahlia Ranji.—In the Cactus section of these flowers, to which *Ranji* belongs, there are several varieties which are exceptionally dark in colour, *Matchless* and *Night* being of this number, but which the above now appears to supersede. The colour is a most intense maroon-black, the tips of the florets of a brighter hue. Individually the flowers are not large, yet ample for all purposes. It is to be hoped that size will never be aimed at in this essentially decorative group. Huge flowers are never needed in decoration, if indeed they are on the exhibition table, and much less so in their truer sphere in the garden.

Chrysanthemum Crimson Pride is a useful Japanese decorative variety, although as staged at the recent floral committee of the National Chrysanthemum Society the plant must have been severely disbudded. Each flower was shown on a stout stem, and although cut from the open the flowers were not in the least affected. The colour is a chestnut-crimson with a bright bronze reverse, florets rather short, broad, and of good substance. The blooms very much resemble those of an old variety known as *Souvenir de M. Menier*, certificated some years since. The habit of the plant is good, and it usually attains a height of about 3 feet.—C. A. H.

Clerodendron trichotomum.—This *Clerodendron*, mentioned incidentally on p. 223, has proved a disappointing plant to a considerable number who have tried it. I have no reason to doubt its hardiness, but even in gardens where one would think it likely to bloom early it cannot be induced to flower in the open in time to escape frost. This is unfortunate, as some of us were looking forward to having so fine a plant in our gardens. Even in the neighbourhood of Dublin where I should have expected it to bloom the experience is generally unfavourable, so that

it is, I fear, hopeless to expect it to flower with us in Scotland in the open.—S. ARNOTT, *Carsethorn, by Dumfriess, N.B.*

Michaelmas Daisies from Newry.—I send you a few bunches of Michaelmas Daisies. *Candidus* is the best white. *Cottage Maid* is a pretty shade of rosy lilac and has an excellent habit. *F. W. Burbidge* is of a much deeper shade, and is also one of the best, and *St. Bridget* is very beautiful, its soft blush flowers charming. I also enclose a few of the lateral spikes of *Lobelia Distinction*.—T. SMITH.

* * * A beautiful and varied lot of flowers, showing that the conditions of climate are far more favourable than in the neighbourhood of London and on the south coast of England, where the Michaelmas Daisies are this year very poor owing to the want of moisture.—E.H.

Aster John Wood.—The garden of hardy plants owes much of its interest in autumn to the newer Starworts, now, happily, both plentiful and cheap enough. Since the Michaelmas Daisies have been taken in hand, it is wonderful the progress that has been made. Finality has not been reached, and varieties now considered in the first rank will, it is highly probable, be superseded in future years. Among the best of the white-flowered varieties is *John Wood*, now in bloom here. With large, well formed flowers of pure white, with the exception of the yellow centre, it is of great beauty. It does not grow more than 3 feet high in this light soil, so that it is not so troublesome in the way of staking as some.—S. ARNOTT, *Carsethorn, by Dumfriess, N.B.*

Carnations in early autumn.—Many Carnations, of which *Raby Castle* and *Uriah Pike* are examples, often produce quantities of good flowers in early autumn, but this season the supply is very meagre. This is doubtless in a measure due to the great heat of the year, and is unfortunate, seeing some of the best coloured flowers of the first-named kind may often be secured at the end of the year when cooler days and nights put in an appearance. The effect of the diminished sun-heat is very remarkable, too, in these highly-coloured pink kinds. The other kind is not affected in the same way, and in the average season gives a most valuable second bloom. This season, however, the blossoms are only occasional, though of good quality.

Erythrina crista-galli.—Very few plants of such striking appearance as this have in all probability suffered a similar neglect. Many very old gardens, where one would expect to find fine old clumps of it valued at their full worth, are without a vestige of the plant, yet in flower the plant is quite unique. Some years since in a Herefordshire nursery garden I came across some giant pieces of it at the sunny end of some span-roofed greenhouses, the plants perhaps 7 feet high, and each with a score of growths that gave them considerable bulk. As I saw them in their fullest beauty they were showy and brilliant indeed. I was reminded of the sight by a few flowers at the Drill Hall last week, taken, it was said, from a plant forty years old—a long time for a hardy perennial to occupy one position. The plant is still worth planting, however, in certain positions.—J.

Senecio pulcher.—Some groups of this handsome perennial have been very fine this year, though more especially in those instances where good established pot plants were put out quite early in the spring. It is surprising that this *Groundsel* is not more often grown. For those who require a very late display in the open, what more effective plant could be recommended? Particularly good is it for a September display or even later, where a little attention is given to culture. This *Senecio* is one of those things that repay frequent renewal, an item readily accomplished by means of root cuttings, and where a late display is valued no better way of securing it can be adopted than the following where root cuttings have been resorted to. The largest of these will as a rule be planted out in early spring,

and many flower the same year, but if the smaller plants be confined to pots of small size till June and then shifted into others 5 inches in diameter to be planted out in March ensuing, a fine display may be relied upon. At all times the plant delights in overhead watering. Firm soil, not too rich, is also desirable.—E. J.

Early frost sufficient to blacken Scarlet Runner Beans and Vegetable Marrows has been freely experienced in this portion of the Thames valley during the first three nights of the present week. The former, however, where the bine remained erect is unhurt, but a small portion thrown over by the breaking of the sticks in the upper part, and in consequence forming a table for the dew, is quite black. Right and left of this is still green.—E. J., *Hampton*.

—Seldom have we been visited in this locality with frost of such severity as that experienced on the 24th, 25th and 26th of September last, when 5°, 7° and 5° respectively were registered here. As may be expected, all such tender things as Dahlias, Vegetable Marrows, French Beans, &c., were cut down and blackened, while it necessitated the hasty housing of Chrysanthemums. The worst effects have been felt in the kitchen garden, as in the flower garden, which lies some 70 feet to 85 feet higher. Such tender things as Heliotropes and Cupheas are hardly touched. In the neighbourhood the same amount of damage has been done in cottage gardens, and the tops of late Potatoes have suffered considerably. It is to be feared that many will gather their Apples and Pears under the impression that it will not be safe to leave them longer on the trees. No greater mistake can be made, as, although tender vegetables and flowers may be considerably damaged, if not killed outright, the above-named fruits have in reality sustained no harm. These, especially the late-keeping kinds, should therefore be left on the trees as long as possible, and not be gathered one day earlier than is necessary.—A. W., *Hereford*.

Oxalis lobata.—There are not many of the Oxalises grown in gardens as hardy flowers, and some interchange of experience regarding the various species would be of service to many. The nomenclature is doubtful, partly owing to the way in which the plants become mixed if grown in beds together, and also from seedlings growing where they are not wanted. I think there is, however, little doubt of the correctness of the name of the little Wood Sorrel which is the subject of this note. I have had it since 1894, when I received it from a nursery near London, with the recommendation to grow it in a frame. This was not adopted, and as it has been always unprotected since received—in May or June of the year mentioned—I have now no fear of its hardiness here. It is grown in light sandy peat and is in a well-drained position on rockwork. Here it comes into flower in September or October—this year in the middle of the former month—and lasts until severe frost comes. It forms a dwarf plant, only about 3 inches high, and has bright glossy yellow flowers margined with red. According to some they should be spotted with red, but here the flowers are pure yellow when open, the red margin being seen when the blooms are closed. Like other Oxalises, the flowers only open in the sun, and this to some degree detracts from their value in the garden. *O. lobata* is, however, very interesting even when closed, the pretty way in which the petals are twisted when folded and the narrow red margin making the flower very pleasing. For the rock garden in late autumn such plants as the lobed Wood Sorrel are particularly valuable. It was introduced from Chili in 1823.—S. ARNOTT, *Carsethorn, by Dumfriess, N.B.*

The weather in West Herts.—During the past week the days have been, as a rule, warm, while the nights, on the other hand, have all proved more or less unseasonably cold. On three nights the exposed thermometer showed from 2° to 4° of frost, but no harm whatever has been

done in my garden by any of these frosts. The temperature of the ground has again fallen, and is now, both at 1 foot and 2 feet deep, only about 3° warmer than is seasonable. Rain fell on the 28th ult., but only to the depth of about a tenth of an inch. No rain-water at all has come through either percolation gauge since the end of August. On the 23rd ult. the sun shone for 10½ hours, which is the longest duration as yet recorded here so late in September. The past month was a most remarkable one in many respects. It was the warmest of the fourteen Septembers of which I have here any weather records. The days were, as a rule, much warmer than the nights; in fact, in the same month in 1896 the nights were decidedly warmer than they were this year. Taking the month as a whole, the only September in any way approaching it as regards warmth was that of 1895, which was 1° less warm. On the six hottest days the shade temperature rose respectively to 83°, 84°, 90°, 83°, 83°, and 88°, the previous highest in the same month being 82° in September, 1895. At 2 feet deep the temperature of the soil rose in the middle of the month to 67°, and at 1 foot deep to 72°, the previous highest for September being respectively 64° and 69°. Rain fell on three days to the total depth of little more than a tenth of an inch, making this not only the driest September at Berkhamsted, but also the driest month but one (February, 1891) during the forty-three years for which rainfall records are here available. The sun shone on an average for seven hours a day, or for a longer period than in any preceding September. In the same month in 1895 the record was, however, very nearly as good. The most exceptional feature of the weather of the month is, however, found in the small quantity of moisture in the atmosphere. Taking 100 as representing the air completely saturated with vapour, the relative humidity for the month at 3 o'clock in the afternoon comes out as 48; whereas in no previous September has the average relative humidity at that hour been lower than 56. On the hottest day of all, the relative humidity at 3 p.m. was only 30. I am writing this report on the 28th ult.; should any decided change in the weather take place during the next two days September may easily lose the position I have here given it as the driest but one in the last forty-three years. But whatever happens the particulars given as to temperature and sunshine must hold good.—E. M., *Berkhamsted*.

New park for Forest Hill.—The district of Forest Hill will shortly have the benefit of a fine open space under the care of the County Council. Mr. Horniman is now laying out a park there, and there are reasons for believing that when the work is finished the London County Council will be asked to take it over.

Keeping Walnuts.—Will some of your readers oblige by informing me of the best way to keep Walnuts in a fresh and eatable condition?—J. G. W.

Bog garden.—I have a shady corner at the angle of north and west walls, at the end of a lawn. I want to make a bog garden of it. There are about 4 or 5 square yards. How shall I go to work? Is it necessary to put in a cement bottom? The soil is rather stiff and retentive.—A. E. GIBBS.

Ferns in porous vases.—Will some reader tell me how to treat Maiden-hair Ferns in the porous vases originally procured at Malta? Of twelve brought to this country only one survives in a satisfactory condition. That one has been well watered, or rather the vase has been filled with water every day, and it is a mass of foliage 2 feet across. But now bare patches are appearing. The owner, a lady at Hoyleake, would be glad to know what must be done to the plant; whether it should be cut down, or whether liquid manure should be given. Any information will be gladly received.—W.

ORCHARD AND FRUIT GARDEN.

GATHERING FRUIT.

It is surprising what an amount of good fruit is wasted by gathering too soon or too late. Apples, as an instance, are left on the trees in many cases until a few of the forwardest drop, and these are often the finest and best samples. Then the whole of the fruit on the tree is gathered, some ripe, but perhaps the majority only half ripe. On large old orchard trees, where ladders have to be used, there is some excuse for this, as not only does it save a lot of trouble, but the trees are easily damaged with a heavy ladder. On the small bush and espalier trees, however, there is no such excuse, and with very little trouble the fruits may be looked over, first when the most forward are ready, again in a week or ten days afterwards, finishing by taking off the smaller and unripe samples that it is evident will never reach maturity. The time to gather Apples is easily known by anyone with a little experience. It is wrong to wait until they are so loose as to apparently fall into the hand, but no great force should be needed to sever the fruit from the tree, nor should any wood come with the stem. The stem must not slip out of the fruit, but should break at the natural division. Apples on a light soil are ready to gather as a rule before those on a heavier one, the length of time the samples keep depending upon the proper manurial constituents being in the soil and their being in a proper atmosphere and temperature after gathering. It is not everywhere that a sufficient amount of shelf room exists for storing all the fruit, and in such cases I have had good results from packing the fruit as it comes from the tree into champagne boxes. These boxes are taken to the trees and all selected fruits placed in them. No straw, paper, or anything else is used, and the wood the boxes are made of is absolutely odourless. The boxes when filled are taken to a cool lock-up shed; if possible they are allowed to remain

open a day or more before storing away, but as the lids are only narrow strips of wood, this does not make any material difference. It is surprising how well many of the thin-skinned Apples keep when treated in this way, and there is nothing to fear as regards a decayed fruit damaging a sound one, provided, of course, all are carefully gathered and packed. The least abrasion of the skin will spoil a sound fruit, but I have, when taking the fruit out, found a specimen quite rotten with every surrounding one sound as when it was packed. The only thing is, great care must be exercised in handling, and every fruit showing the least bruise must be rejected. In the case of early developing kinds of the Codlin type the fruit will be found to keep much better if gathered before it gets too ripe. In the latter state it is almost impossible to handle the fruit without bruising it.

Much that has been said of Apples applies to Pears, but a knowledge of varieties is of importance here. The earlier kinds, such as Jargonelle and the smaller Doyenné d'Ete, and even later Bon Chrétien and Souvenir du Congrès, should all be gathered before they are quite ripe and kept in a cool fruit room to finish. Jargonelle comes quickest to maturity after gathering and soon passes its best. Large sound specimens of Bon Chrétien keep better, but it takes a little experience to catch it just right. If allowed to lie about after removal from the fruit room it loses its freshness and becomes mealy. Souvenir du Congrès is somewhat similar in its requirements, and large, well-grown samples are better than those of Bon Chrétien and somewhat later. Most of the varieties that ripen later than these may be left on the trees until they part readily, though I have known some of the earlier of the Beurré race much better in flavour when they have been gathered early with a view to keeping a succession for dessert. Marie Louise I have often hastened in this way with no ill-effects upon the flavour, especially samples grown on a warm wall, but as a rule this and all

later Pears should, unless birds are very troublesome, be left on late.

In gathering Peaches and Nectarines on a hot day, a thin cotton glove may be put on, this, according to my experience, being far better than a pad of wool, as sometimes used. This deadens the sense of touch in the fingers and it is unnecessary, for anyone may easily tell when a Peach or Nectarine is ready to gather by lifting the fruit and thus straining the stem a little. Unfortunately, wasps and large flies too often settle the question of when Peaches, Plums and other soft fruit shall be gathered. The various destroyers are excellent under glass, but practically useless in a hot, dry autumn out of doors. White garden net placed over the fruit is the only safe preventive, and this of course is only feasible on a small scale, as it must be tied very closely to keep these insects away. Still, if done early enough it keeps birds off in the first instance, and these often commence the mischief, the insects finishing it. C. H.

Two valuable Nectarines.—Early Rivers is a grand acquisition, and as it does so well on open walls it ought to be found in every garden. For years I have found no variety equal to Lord Napier, but this is now superseded by the newer variety, which, being earlier, equally as large, and as hardy and free cropping, is a great gain. Lord Napier must not be despised, as there is room for both. The newer Cardinal is less useful, as it is of little use for open walls. When forced or grown in a cool house it is a beautiful fruit, and those who value size and quality will include it in their collections. It is also earlier than the two varieties mentioned above. A small plant on a back wall did so well that I intend to grow it more largely.—G. W.

Peach Marquis of Downshire.—This Peach is but little grown. In many gardens it is grown under the name of Royal Ascot, a name given by the raiser when first brought out. Few varieties are more reliable as regards cropping, and being late it is valuable on that account. Fortunately, most of the September Peaches are of good flavour if the season is favourable, and this variety

is one of the best in this respect. The fruits are not very large, but they are freely produced, the quality also being good for a late Peach. I do not grow it under glass, so am unable to note its quality. It is one of the best late September kinds, and growing well in a poor soil it should find favour. Many need late Peaches, and this variety will be found good if the soil is well drained. My trees occupy a rather light soil.—G. W.

Peach Late Devonian.—I noted the good qualities of this Peach when given an award at the Royal Horticultural Society's Gardens, Chiswick, in 1894, and a first-class certificate recently, and have since proved it to be one of the very best for late use. It is a handsome fruit and of good colour. The flavour is excellent, the fruits being large, the exposed side dark crimson, flesh pale yellow, very melting and juicy, with a rich flavour. It does grandly on a south or west wall. The tree is vigorous, and was raised from crossing Belle de Vitry and Late Admirable. I find it is of much better quality than Late Admirable and a better cropper. With me Late Admirable is not reliable, whereas Devonian for two seasons has been excellent, the trees making a splendid growth. I have not grown it under glass. I admit the season has been favourable for ripening early Peaches, but some varieties had a very poor crop owing to the severe cold in the spring. The variety in question was not at all injured.—G. WYTHES.

MILDEW ON VINES.

My Vines having been for a second time attacked by this much-to-be-dreaded pest, I perused with the greatest interest the notes by Mr. Riddell on page 228, together with those from Mr. Iggulden in a previous issue. Until last year I had had no experience with mildew on Vines, and a remedy sent and guaranteed by a very successful Grape grower in the autumn of last year was bailed with delight. During the winter the usual dressing of the Vines, roof cleaning by scrubbing, lime-whiting the walls, and the removal of the surface soil were carried out, hoping that mildew had not "come to stay," but such anticipations became only a myth, for by the time the Grapes were ready for thinning, occasional berries were found coated with the dreaded fungus. Even then, by careful and daily search for the isolated berries, and their prompt removal, there remained slight hopes that its progress would be arrested. This, too, was denied me, particularly in two late houses containing Black Hamburg and a mixed collection respectively. The remedy that raised in me such decided hopes was sulphide of potassium, a specific that has had such an oft-repeated notice during the past season, particularly among Chrysanthemums, with which there arose such a scare in the autumn of last year, by reason of a new fungoid disease attacking them, and in some cases so virulently. I saw one large collection so hopelessly ruined by its presence last November that I had some misgivings as to going into the house among the infested plants, fearing that I might carry home the spores sufficient to set it growing among my own stock, which was free. Fortunately, however, nothing came of the dread thus raised, and I had hoped the same favourable immunity would obtain in the case of the Vines.

The advice as to applying the sulphide of potassium was zealously followed out, although the course was very simple and its preparation devoid of that infinite detail recommended for other decoctions. A half ounce of the sulphide dissolved in a gallon of water is the usual quantity recommended, and with this the rods were thoroughly soaked by the use of a brush. This was the finishing touch put on after the other preliminary work had been done, namely, the cleaning of the house and the border surfaces. In houses where only slight trouble was given a dusting of sulphur was applied to the affected bunches, and a coating of the same put on the hot-water pipes, which were frequently heated so as to diffuse the fungoid-destroying

fumes freely in the air during the evening when the ventilators were closed. The structures themselves and the means provided for ventilation probably are in favour of the growth and spread of the disease, and the arrangement of the pipes facilitates its progress rather than affords the required assistance in combating the enemy.

Finding that the houses successively started almost in every case developed symptoms of mildew as they advanced to the stage for attack—the setting time—I was determined to test in one house, or division at any rate, what the sulphide would do applied as an ordinary insecticide by syringing the Vines, bunches and all, immediately previous to and after the setting of the crop. It was in this house where mildew became more rampant than in either of the other divisions, and thus my hopes, which in the autumn previous had given rise to so much confidence in the declaration of a successful battle with what always proves so troublesome a garden enemy, met with failure. I then tried sulphate of iron, giving the borders of the infested houses a very light sprinkling. The quantity advised for applications in solution being only an ounce to a gallon, the smallest quantity that could be put on in a dry state should suffice. This was applied when other means failed, with the hope that by its transmission through the roots and sap of the Vines some good might be done in the storage of sap for future growth, if it did not actually arrest its progress during the current season. I shall certainly endeavour by the means adopted and advised by Mr. Riddell to make a more hopeful start next year by testing the virtues of sulphate of iron as suggested, and if the results favour those obtained in your correspondent's case, I shall hold him a good benefactor to the Grape-growing community.

In sulphur itself I have not so much confidence. I have little doubt but that there are varying qualities in sulphur as in every other manufactured article, and I may not always have been fortunate in choosing the best for the purpose, and to some extent this may apply also to the iron sulphate, although this latter was obtained from what appeared to be a good source. It would be very interesting if any other reader could supplement Mr. Riddell's experience in the effectual riddance of mildew by the use of sulphate of iron. W. STRUGNELL.

GROSS-GROWING VINES.

THERE are certain naturally gross-growing varieties of Grape Vines which under ordinary culture invariably refuse to fruit freely, needing special root treatment to ensure fertility. If a house can be spared, it pays to devote it to the growth of these strong-growing sorts alone, as then their wants can be attended to. When planted by themselves the best plan is to confine them to an inside border, making only about 4 feet of this for a start and not more than 2½ feet deep, the compost consisting of a medium loam with no manure of any kind but a liberal supply of old mortar rubble. The border should be made very firm and no increase in width made for two years. At the end of that time another couple of feet may be added, and this with annual top-dressings will probably carry them on for several years. Under these conditions the wood will be of moderate thickness, becoming well ripened by autumn, bunches being correspondingly numerous. Amongst these strong growers may be mentioned Trebbiano, a useful Grape for spring use when ripened in sufficient heat, and one which if well thinned does not damp off in foggy weather like some sorts. Barbarossa also responds well to this mode of treatment, but needs in addition to a non-stimulating larder to be carefully pruned, always leaving a good eye for bunch-production. Barbarossa has been termed a coarse Grape, but when properly grown

it is the very reverse of this, and even improves by hanging in the fruit room. The true Gros Maroc often produces a large percentage of strong bunchless laterals when treated liberally at the roots, and is much improved by being grown under the above conditions. I say the true Gros Maroc, as I think, with Mr. Iggulden, that many of the large bunches exhibited as Gros Maroc are Cooper's Black. Duke of Buccleuch frequently produces strong sappy laterals, showing bunches but sparingly, and is the better for restriction and poor diet, developing the well-known spot far less than when highly fed. I have found, however, that Golden Queen is a capital stock for grafting or inarching it on. Gros Colman, under what is generally called good culture, often refuses to colour its berries, the young vigorous rods also suddenly losing their leads by the foliage becoming seared. In shallow, poor borders it is much more reliable. Finally, that sweetest of all late white Grapes, Royal Vineyard, is prone to grow too strongly when highly fed, and not only gives more and better bunches in the above class of border, but also sets better, it being naturally capricious in this respect. More varieties might no doubt be added to the list. J. CRAWFORD.

Pear Beurre de Capiaumont.—I do not think a more profitable Pear for market could be named than Beurre de Capiaumont. It succeeds equally well as a standard or bush, invariably carries a full crop, the fruit being of just the right size, its handsome form and bright russet colour adding to its value. It also keeps sound for some time after being ripe if stored in a cool, even temperature. The flavour is sweet and refreshing. I consider it a better Pear for profit than Fertility, which is often recommended. As a garden Pear it does remarkably well as a cordon, espalier, or trained wall tree, never needing root-pruning, as it bears freely in quite a young state.—N.

Peach Sea Eagle.—I have just gathered from a south-west wall the last fruits of this, one of the best of the September Peaches. Large Peaches are always in request, and so far I have never found a large fruit of the above deficient in quality. I am aware there are some very poor late Peaches, but Sea Eagle is not one of them, and anyone who studies quality in these fruits will do well to include Sea Eagle in his collection. It rarely fails to crop, and the trees make a good growth if given ample space. It is a great mistake to crowd the wood of late Peaches, as in unfavourable seasons the trees need all the sun possible to mature the fruit and the wood. I have this variety both indoors and on two aspects on open walls, and in all positions it is reliable. It keeps well into October if grown on a west wall, and is a very handsome fruit of a bright colour, and, being late, often escapes spring frosts. It was raised from that delicious early variety the Early Silver.—S. H. B.

Planting late-formed Strawberry runners.—It is the general rule to plant not only early-formed runners of vigorous sorts of Strawberries, but also those of late-formed, weaker-growing varieties in their permanent quarters in autumn. Consequently such sorts as Loxford Hall, Waterloo, and Elton Pine, which are often sently rooted in September, take to their new quarters indifferently and do not prove profitable the following summer. I think the better way is to plant these out somewhat closely in nursery beds in a semi-shaded position, transferring them to the fruiting quarters in spring. They then have the summer before them in which to make bulky plants for free-fruiting the second year. This may appear to be a loss of time, but in reality it is not so. Even when the best of runners are secured, Waterloo seldom proves remunerative the first season when planted in autumn, but some growers have found it fruit freely on plants two and three years old,

I am not an advocate for spring planting in the case of the free-growing varieties.—J. C.

Shading Pine-apples.—Shading Pine-apples is often carried to excess. Doubtless a slight covering of thin tiffany or frigi-domo is beneficial in light, airy houses and pits, but it should only be given during the hottest hours of the day, say from 11 a.m. till 3 p.m. When the blinds are lowered immediately after breakfast and not rolled up till late in the afternoon, the plants may grow vigorously enough, but they will lack that bronzy appearance and maturity which alone qualify them for early fruiting. When not started early, but allowed to come on gradually, liberal shading is not so harmful, although in every case the thinnest material applied on the give-and-take principle is best for Pines. Roller blinds, though more expensive, are preferable to a permanent coating of whitening, as they can be lowered and raised at will. When improperly ripened plants are started early they frequently make a second growth instead of throwing up fruit.—N.

ORCHIDS.

LELIA AUTUMNALIS.

In every collection where possible a compartment should be set apart for the Mexican species of *Lælia*. They are well worth the attention, and a small house primarily intended for their accommodation will be found very useful for many other beautiful and useful species. The species named above is one of the finest of this class, keeping up a display over a very long season, and comprising a large number of distinct varieties, so that from the present time until the middle of winter there will not be a dearth of flower where a representative collection of this species is grown. It is a well-known kind, introduced as far back as 1836, when it was imported from Mexico by a Mr. Taylor, a Liverpool grower. Being a widely-distributed plant in its native haunts, other collectors of trade firms soon sent it home in quantity, since when it has never been absent from the Orchid collections of this country. Immense plants are occasionally imported and offered at the sale rooms, but, showy and fine as these are, for general utility smaller specimens are better, the large masses having often a lot of bare back pseudo-bulbs, which when the plants are broken up break into growth, this increasing the number of flower-spikes and leads and being more satisfactory in every way. Its natural position is one entirely exposed to the sun, and under cultivation the plants will be found to do best in an unshaded house, or at least where the blinds are only lowered during the hottest part of the day in summer. Although the plants do not relish a high temperature caused by fire-heat, the sun shining fully on the house will bring it up to rather a high figure, and it is none the worse for this as long as air in abundance is left on. The growth made under these conditions is just what is required, but if the same heat were kept up by firing in dull weather the plants would suffer. As to receptacles, there is nothing better than trellised rafts with a thin compost of peat and Sphagnum, but where a large collection is grown a few will also have to be grown in pots on the stages. For these also the compost must be kept thin over good drainage, as a great deal of water is needed while the growth is active. It must be applied every day, in fact when very hot and dry, for the amount of sun and air allowed leads to such rapid evaporation that the compost dries directly. This is when the plants keep healthy; in a heavy or close compost and large pots they cannot thrive, but under the conditions given above they

flower freely and remain in health for a great many years. During the winter give the plants sufficient water to prevent shrivelling, and keep the atmosphere about them cool, airy, and comparatively dry. II.

Vanda multiflora.—One occasionally comes across plants of this species, which is really more of a botanical curiosity than a good garden Orchid. The colour of the flowers, which are very small, varies a little, a plant noted lately having tall, erect spikes of greenish and white blossoms. The plant does well under cultivation in a carefully shaded house kept at a stove-heat and the atmosphere well charged with moisture. The water supply to the roots must be very free as long as these are growing, but while at rest much less suffices. Pot in clean Sphagnum Moss, and treat as for large-growing Vandas generally.

Vanda Kimballiana.—Flowers of this popular species come from several correspondents, and show how useful the plant is for cutting. It is not everywhere a success, and this I think is principally owing to the great heat some cultivators still think necessary to grow it. Only the other day in a fairly large collection I saw what should have been a nice batch of it, but so weak from being kept in a moist, shady and very hot house that the flowers were very poor in size and washy in colour. The cool end of the Cattleya house is quite warm enough for it, and plenty of light should reach the plants from all sides.—H.

Oncidium trulliferum.—This uncommon species is now at its best, and the tall panicles of deep yellow flowers with their brightly coloured markings and crests are very handsome. The pseudo-bulbs are about 6 inches high, thin and compressed, of a bronzy green hue. The plant is a native of Brazil, and does best in an intermediate temperature. The pots must be of medium size only, but perfectly drained, and great care is necessary in preparing the compost owing to the large amount of water required by the plants during the growing season. While at rest a drier state of the atmosphere and less moisture at the root are necessary, or few flowers will be produced.

Houlletia odoratissima.—The flowers of this Orchid are very distinct in colour. They occur upon tall, erect spikes, the sepals and petals being bright red, the lip principally white, of very singular structure, and resembling in a botanical sense that of a *Stanhopea*. The leaves are stalked, deep green, and ribbed, occurring singly on the top of the pseudo-bulbs. II. *odoratissima* is a Colombian species, and grows naturally on the banks of streams. Under cultivation it thrives well in the coolest part of the Cattleya house, and in order to keep insects such as red spider in check the atmosphere should be as moist as possible, and overhead damping should be freely resorted to when the weather permits. The water must be applied in the form of a fine spray several times daily. It is risky to water heavily, and, owing to the water settling on the compost, it is difficult to tell whether or not this is dry. The compost should consist of Sphagnum Moss well chopped, loam and peat fibre, with plenty of broken charcoal, this being firmly placed in rather large pots or pans over good drainage. Water freely while active growth is going on and while flowering, but diminish the supply a little afterwards. Shade rather heavily in hot weather, but in winter bring the plants well up to the light.

NOTES AND QUESTIONS.—ORCHIDS.

Lælio-Cattleya Eunomia (*Lælia punila* × *Cattleya Gaskelliana*) is a remarkable hybrid, having the intermediate characteristics of both parents. The sepals and petals are pale rose, of fine form and substance, the lip wholly rich crimson-purple on the front lobe, the side lobes rose, shading to yellow, with some brown lines at the base. This beautiful hybrid was raised in Messrs. Veitch and Sons' nurseries. It was

recently exhibited at the Drill Hall, a small plant carrying a two-flowered raceme.—H. J. C.

Cattleya Wendlandiana (*C. Bowringiana* × *C. Warszewiczii*).—This is one of the finest hybrids that has been procured from *C. Bowringiana*. It has the intermediate characters of both parents in growth and in the shape of the flowers. The sepals and petals are deep rosy lilac, the lip rich rosy crimson, becoming suffused with velvety crimson in front of the yellow discs at the front of the throat. The side lobes are pale rose, with some yellow at the base. It was raised in Messrs. Veitch and Sons' Langley Nurseries, and was recently exhibited at the Drill Hall.—H. J. C.

NOTES OF THE WEEK.

Ramondia pyrenaica.—It is very rarely one sees a flower of this in the autumn season, yet one plant out of many in the rock garden at Kew has produced a few blooms. It is not a complete flowering such as is given in spring, but I never before remember seeing even a solitary bloom at this season of the year.—J.

Erigeron mucronatus.—This often flowers for a long time in the early autumn of each year, and though a Daisy to all intents and purposes, provides variety by its various coloured ray florets. The plant deserves to be grown in the rock garden or other suitable spot if only for its freedom of flowering and the little trouble it entails at any time.

Thunbergia grandiflora.—Among stove flowering climbers very few can boast of a greater freedom than this showy species. The plant, too, is of fairly easy culture. The large mauve shaded flowers, too, are very showy, and though not long-lived individually, are quickly followed by others. In this way the plant is attractive for a long season.

Kniphofia Nelsoni.—No species is more deserving general cultivation than this, with its slender stems and brilliant spikes of flowers. As a profuse flowering kind this has no equal, and the general uniform size of the stems is such that it is among the best for cutting. This the majority are not suited for by reason of the large stems and heavy heads of bloom.

Aster Amellus Riversea.—This, I think, is the best of its race. With the exception of the colour, the growth, habit and hardiness, as well as freedom of flowering are identical with the best forms of *Aster Amellus*, the colour being an exceptionally rich and dark violet-purple. The variety originated with Mr. Prichard, of Christchurch, a few years since. Even in the smallest sprays its superiority is at once evident.—J.

Inula Roylei.—When most of the *Inulas* are past and for the time forgotten, the above appears inclined to maintain a more profuse flowering, and its large orange-coloured heads are very showy. So far as the colour is concerned there is abundance in the garden at the present time, but this species by its dwarfness is more suited to certain positions in the rock garden, which at the moment is not overdone with flowering plants of any kind.

Aster Madonna.—This Starwort, which belongs to the *Novi-Belgii* section, is beautiful enough to deserve inclusion in the gardens of those who admire these fine late-flowering plants. The flowers are large, with pale soft yellow centre and pure white ray petals. The plant is also a very profuse bloomer, and might well have a place beside *Aster John Wood* as among the finest of the white Starworts. At Summerville, Dumfries, it was in full bloom the other day.—S. ARNOTT.

Papaver rupifragum var. atlanticum.—This perennial Poppy is now giving a second crop of flowers for the year. When the first blooms were over the old stems were cut down, and now quite a number of the pleasing orange-salmon coloured flowers are open. Like all the *Poppies* in this garden, it produces too many self-sown seedlings if the seed of all the flowers is allowed to ripen, so that early cutting away of the seed-pods is an advantage in two ways by both reducing the number of seedlings and giving us late flowers.—S. ARNOTT.

Phloxes Sesostris and Cameron.—In looking over the plants in the garden of Colonel Blackett at Arbigland, Dumfries, the other day I was struck with the large size, good form, and

deep colour of *Phlox Scsestris*. The dry weather had told upon the growth of the plant, but it is seldom that one sees a finer *Phlox* than this, numerous as are the dark-coloured varieties. With smaller flowers, but of a beautiful shade of light pink, was Cameron, a *Phlox* which I cannot recollect to have seen before, although the name is familiar to me.—S. ARNOTT.

A new form of *Galanthus Elwesi*.—From Mr. Edward Whittall, of Smyrna, have come this year bulbs of a newly-discovered form of *Elwes' Snowdrop*. Mr. Whittall says this is the largest and finest form of *G. Elwesi* he has yet seen, so that those of us who have received bulbs will eagerly look forward to their flowering. As with the fine *G. ochrospeilus*, it is improbable that this new *Snowdrop* will show its true character for a year or two. If finer than *G. ochrospeilus* it will indeed be an acquisition, as such forms of *G. Elwesi* are, to my mind, coarse and unrefined.—S. ARNOTT.

***Helianthus orgyalis*.**—Among the perennial Sunflowers we have none to equal this for graceful habit and for effect in the garden. Its long narrow leaves, drooping and gracefully disposed, make it a striking plant in the border. The disappointing feature of this Sunflower is, however, its late-flowering habit. In cold localities it never blooms, and even in the south-west of Scotland it is usually cut down by frost before a bloom opens. It is thus of little value in such districts except for its effect as a fine-foliaged plant. For this purpose it is of considerable value.—S. ARNOTT, *Cursethorn, by Dumfries, N.B.*

Carnations from Exmouth.—I herewith send you a few Carnation blooms, all of which, with the exception of *Flora Hill*, are of my own raising. *Flora Hill* is considered the best white in America. You will notice that all, with one exception, have sound calyces and many are highly perfumed. They are thoroughly perpetual in blooming and all of good habit.—W. J. GODFREY.

* * A very fine set of flowers in white, scarlet, pink and yellow. The best are *Lady Gertrude Rolle*, light pink; *Exmouth Gem*, a sweetly-scented flower of a salmon-pink shade; *Flora Hill* and *Bessie Godfrey*, white, and *Mrs. Herbert Stewart*, rose.—ED.

Plumbago Larpentæ is just now one of the most beautiful and valuable of all rock plants, growing with great freedom and flowering abundantly also in any good position. It is not essentially a rock garden plant, as it is sufficiently vigorous, even if deciduous, to take care of itself in the open border. But its dwarfness, its freedom, and its fine colour when in flower appear to fit it for the rock garden. The plant is not in the least particular as to soil, and will grow quite freely in good ground of almost any character. To see it at its best, however, the plant should be grown into good-sized tufts, when the foliage, or at least some portion, will assume a bronzy hue that is distinctly welcome.

Flowers from Liverpool.—I am sending you a few blooms of Carnations. They were planted out last October in a sunny position in the flower garden in some good rich soil freely mixed with old mortar rubbish. Layered every year, much finer blooms are produced. A good few of this summer's layers throw up a succession of bloom till the frosts cut them down. The *Roses* are grown in a bed in the flower garden. These were planted at the end of March. *Niphetos* grows on the roof of the greenhouse. I have been cutting a few blooms all the summer.—J. R. SKITT, *Liverpool*.

* * A very useful lot of flowers. The blooms of *Niphetos* are excellent.—ED.

Flame Flowers from Christchurch.—Mr. M. Pritchard, Riverslea Nursery, Christchurch, sends us some handsome spikes of *Flame Flowers*, including *Kniphofia Triumph*, a cross between *K. aloides nobilis* and *K. comosa*. This reaches a height of 5 feet, the spikes of bloom just over 9 inches long, of an orange-yellow colour. The characteristics of the male parent have been freely

developed, the spike sent having many smaller branches, which produce smaller spikes. *K. citrina* is a rich yellow variety, the spikes rather small. *K. Nelsoni*, also sent, is one of the richest coloured in the family, flower-stalks very slender. *K. corallina* is also very distinct. *Aster Amellus Riverslea*, raised by Mr. Pritchard, is the richest coloured of this section we have seen, an intense dark purple, and very effective in a mass.

***Pratia angulata*.**—This charming little New Zealand alpine was in flower in the garden of Mr. James Lotimer, Nithbank, in the last days of September. In this garden *P. angulata*, which is well worth the attention of growers of alpines, blooms for a long time, and I have not seen it grown better anywhere. Earlier in the season it is, as may be expected, even prettier than in late autumn, and forms beautiful little mounds almost covered with the pleasing white flowers. This plant does not appear to succeed in very dry soil, and I have experienced much difficulty in keeping it. At Nithbank it seems to do best on the level at the foot of a south-west wall, where it is, although in the sun, not too dry. *P. angulata* is also known as *Lobelia littoralis*, but the former name is that adopted in the Kew hand-list. The plant is not considered hardy everywhere in the British Isles, but stands our winters in the south-west of Scotland.—S. ARNOTT.

—Where a dense prostrate carpet of green is desired, this singular little plant will furnish it as quickly as most things, and is also for a long time freely dotted with its white flowers. The most needful thing in its culture is a rather shady spot and somewhat moist, peaty soil.

***Kniphofia modesta*.**—Seen in small plants at the time of flowering, the specific name would appear well chosen and quite applicable, though one is inclined rather to question it when seeing a plant that, if bearing small individual flowers and less columnar in spike than in many of its fellows, attains to a height of 7 feet or 8 feet. The tuft of growth, too, is by no means meagre or even frail, and the name has reference, doubtless, to the flower-spike and flowers alone. Modest these undoubtedly are if we compare them with the vivid colouring and giant heads of some kinds, and singularly pretty as well as distinct is the creamy white shade, which is almost wax-like in appearance. Quite one half of the full length of spike—and this appears characteristic in large and small examples alike—is covered with flowers, singularly short for a member of this race, and reflexed in a way that suggests individually the flowers of a white *Bluebell*. All this is very distinct, and though the species is not quite hardy, it may with advantage be employed among the hardest of the race in the hope of securing a new break among this well-known class of plants. Many of the existing kinds are too much alike, at least for garden effect, therefore a decided break-away may be of some value. The above species is flowering now at Kew.

A "first-class" certificate.—At the Drill Hall meeting of the Royal Horticultural Society on Tuesday, September 20, a first-class certificate was awarded to a shrub called *Ligustrum Walkeri*. It would be interesting to know why. I put this question to an experienced member of the floral committee, who suggested that it was because no one on the committee knew what this *Privet* was. This was probably gentle sarcasm, but I doubt if a better or truer reason could have been given. *Ligustrum Walkeri* is a very ordinary looking shrub that is not hardy, has no beauty of flower, and as an ornamental plant is about on a par with the common hedge *Privet*. It cannot be grown out of doors, and who would fill his greenhouse with such weedy rubbish? It grows on the mountains of Ceylon and on the Neilgherry Hills, and seems to occupy in those regions pretty much the same place that the common *Privet* fills here. When one remembers the plants that the floral committee has passed over and the repeated appeals of the council for greater discrimination and restraint in the awards to plants, it seems like a wanton disregard not only of the council's repre-

sentations, but even of the society's credit, to give a first-class certificate to an uninteresting and comparatively worthless plant like this *Privet*. One does not expect the floral committee to be infallible, but it might, all the same, reasonably be expected to see (as the council does) how important it is that the honours the society distributes should not be cheapened.—B.

The great drought.—The excessive drought is becoming alarming here, as elsewhere. Ponds that have never been known to fail before are now quite dry and hard at the bottom, and water is extremely difficult to obtain. The state of winter crops seen as one goes about the country is quite distressing, and I noticed recently that the market gardens by the railway between Bishops Cleeve and London were in a deplorable condition. The outlook for winter vegetables is very bad, and prices must rule high if a living is to be got out of the sorry remnant which will be available for use. Even where green stuffs, Turnips, &c., are still alive the quality will be very poor, as the Brassicas are blue and swarming with caterpillars, and Turnips already woody. Deep culture is the only means of preventing a breakdown in such seasons as this, and those who advocate and have the means of carrying this out have good reason now to congratulate themselves on the policy. As I write (October 5) a slight change has taken place in the weather; a faint drizzling rain is falling, but the barometer is still high and steady.—J. C. TALLACK, *Livermere Park Gardens, Bury St. Edmunds*.

Notes from Baden-Baden.—During July and August a small lot of a half-shrubby *Campanula*, *Adenophora Potanini*, was very showy. It is a native of Central Asia and perfectly hardy. From a permanent rootstock come four to six shoots, 1 foot to 2½ feet high and gracefully arching, bearing numerous pale blue bells, about six to ten on a shoot. It is a graceful plant. Among *Colchicums*, *C. giganteum* is quite as large-flowered as *Bornmulleri*, but the former is deeper in colour. *Liatris graminifolia* flowering now (October 1) is perhaps the best. It is not so tall and weedy as some of the other species, but the colour is very pure—a bright deep purple. The white variety is lovely, but as yet it is very rare. *Salvia azurea grandiflora* is also a desirable garden plant. It grows 3 feet to 4 feet high, and has numerous terminal-whorled spikes of bright sky-blue flowers. I have succeeded in obtaining a large lot of *Dianthus callizonus*, which seems now quite safe and growing. It is one of the greatest beauties among alpines, but has peculiar wants in cultivation, which must be attended to. It wants artificial shade and syringing during the hot summer days.—MAX LEICHTLIN, *Baden-Baden*.

Belladonna Lilies at Kew.—Among the hardy flowering bulbs at Kew at the present moment, none is so effective as this lovely autumn *Amaryllid*. Scores of umbels of the handsome flowers are now in beauty. Some of the forms, and there are many which suggest the probability of a free-seeding character in the native haunts of the plant, are beautiful. There are scores of spikes just emerging from the soil that, if weather permits, will make gay the same spot for weeks to come. In this way, where the plant is freely cultivated, there is scarcely any limit to its profuseness of flowering. But beautiful as all these appear in the narrow border outside the *Orchid* house in these gardens, their beauty is easily eclipsed by a giant of the same race growing in a frame beside the economic house. Here may be seen an example upwards of 3 feet high, bold and massive, and carrying a giant head of bloom, finely proportioned withal, and which is composed of some thirty handsome, richly-coloured flowers. Individually, these are rather shorter in the trumpet than some, the rich rosy purple-carmine flowers very telling. So handsome a kind is well worth the time and trouble that fertilising and seed-saving would involve. The colour is very rich and the flowers of greater substance than usual.

STOVE AND GREENHOUSE.

LAPAGERIAS.

THE Lapagerias here are planted in stone tanks 4 feet by 18 inches and 3 feet deep, with about 12 inches of rock stones as drainage. The com-

be allowed to become dry at the roots. On one of the shoots shown there were 105 blooms, and on the other seventy. W. A. MILNER.

Totley Hall, Sheffield.

Pelargonium Souvenir de Prinee Albert.—I have tried a great many of the newer varieties

Sprays of *Lapageria alba* from flowers sent by Mr. W. A. Milner, Totley Hall, Sheffield.

May. The colour is very pleasing and has none of the disagreeable purple tint which looks so undecided under artificial light.—H. R.

Campanula isophylla alba.—The beauty of this well-known plant was brought home to me very forcibly the other day, when I saw several baskets full of it in a dwelling house window in Bury St. Edmunds. They were excellent examples of window plant culture, large, full of flower, the pure white as usual showing very finely against the deep green foliage. It is strange that this beautiful plant is not more often met with in large gardens. Presumably it is so common as a window plant in town and country that gardeners think it beneath their notice, but really it would be difficult to name anything prettier. The simplest culture suits it and it never fails to flower.—H.

Thunbergia grandiflora.—This is essentially a stove plant, and for a lofty structure it is a really grand climber, but it is only under such conditions that it will flower in a satisfactory manner, as if cramped within narrow limits or heavily shaded, its large showy blossoms may be sought for in vain. The leaves of this species are each about 6 inches long and hastate in shape, while the flowers, which are 4 inches across, are pale blue lined with a deeper tint, while the interior of the throat is almost white. This *Thunbergia* is a very common plant in India, being often met with festooning trees and in many other different situations. It needs little if any shading: indeed, it is just the thing to clothe the roof of a lofty structure and thus provide a certain amount of shade for the plants underneath. There is a white-flowered variety of this (*T. grandiflora alba*) which is, except in the colour of its blossoms, a counterpart of the type. A pleasing effect is produced by growing the two in conjunction. Nearly allied to the preceding is *T. laurifolia* or *Harrisi*, as it is often called. The foliage is quite distinct, being, as suggested by its specific name, like that of a Laurel, while the flowers are more of a decided bluish tinge.—H. P.

Ficus falcata.—This is a welcome addition to the creeping forms of *Ficus*, of which the small *F. repens* and the still tinier *minima* have been long grown in our gardens, and for covering damp walls, clothing the surface of large pots, draping the edges of the stage, or for purposes such as this they have few, if any, equals. The newer form, *falcata*, is of just the same style of growth, but the shape of the leaf is altogether different. It is about an inch long and of a deep green colour. The most prominent feature is its peculiarly curved shape, from whence the name of *falcata* is derived. On a damp wall this *Ficus* will grow quite as rapidly as *F. repens*, with which it may be associated. The whole of these above mentioned are particularly valuable from the fact that they will thrive even in heavily shaded positions. Among the other climbing kinds of *Ficus* somewhat more vigorous in growth than *F. repens* is *F. radicans*, whose leaves are each from 2 inches to 3 inches long and an inch wide. They are heart-shaped at the base, but taper to a point. Of this there is a variegated variety whose leaves are deeply, but irregularly edged with white, sometimes to such an extent that the green portion is very small indeed.—H. P.

Hæmanthus coccineus.—Several species of *Hæmanthus* are very beautiful when in bloom, but some of them are difficult to keep permanently in health under cultivation. This cannot, however, be said of *H. coccineus*, which once it has attained flowering size can be depended upon to bloom year after year provided its requirements are attended to. It is a deciduous species, but the period of rest is July and August, and not during the winter months. The leaves are just now pushing up, and when developed they are both long and broad and of a thick fleshy texture. The plants should be kept in a light, sunny greenhouse and receive a moderate amount of water, while occasional doses of liquid manure will also be of great service, particularly if the pots are full of roots. Then about mid-summer

post I use is three parts bog-peat, broken roughly, the remaining part being made up of leaf-soil, turfy loam, coarse sand, half-inch charcoal and stone chippings. Lapagerias require an immense amount of water during the growing season, and even in winter they ought never to

of Ivy-leaved Pelargoniums, but this old kind is still my best, and I do not know a more useful one. From cuttings taken in early spring I have now good plants in 6-inch pots that are covered with the fine handsome trusses, and these will not be without flower from now until next

the leaves die off, and as soon as they show signs of turning yellow the water supply must be diminished, and finally stopped altogether, the pots meanwhile being kept in full sunshine. Then about the end of August the flower-buds will commence to show, when the plants should be thoroughly watered, and after that kept moderately moist. A few waterings with liquid manure will assist the development of the blossoms. The flower-heads of this species, which reach a height of about a foot or perhaps a little more, are bright red in colour. Simultaneously with the production of the flower-buds the new leaves also make their appearance.—H. P.

Specimen Cockscombs.—At a flower show held at Sandy, Bedfordshire, in August last, some remarkably fine Cockscombs were shown by Mr. T. Lockie, The Gardens, Diddington Hall, Huntingdon. It is customary at many country flower shows to have a class for Cockscombs, but they are generally somewhat poor examples. At Sandy Mr. Lockie staged four specimens of marvellous size. Opinions were hazarded as to the size of their perfect combs. When measured it was found that the length of combs from end to end was 26 inches and the breadth of the combs 16 inches. Mr. Lockie informed me that the seed of these magnificent Cockscombs was sown on February 28 in light soil and raised on a mild hotbed with a temperature of 70°. A Melon frame is generally employed for raising plants. As soon as the seedlings were large enough to handle the strongest of them were potted singly into small pots kept near the glass and re-potted as soon as the pots became filled with roots. The plants are not allowed to become pot-bound, to suffer from want of water, or become drawn from closeness of atmosphere. They are syringed every evening with tepid soft water, which serves to keep red spider in check, the crested *Celosia* being subject to its attacks. As soon as the combs begin to show themselves, and a selection of the most promising and best coloured can be made, the plants are transferred to their flowering pots, which are 7 inches to 8 inches in diameter, and potted in a compost of good loam, a little manure from a Mushroom bed, leaf-soil, a good sprinkling of coarse sand, with some bone-meal added, the drainage of the pots being provided by the use of quarter-inch broken bones.—R. D.

FLOWER GARDEN.

MUTISIA DECURRENS.

THERE is perhaps no more beautiful climbing plant in the whole of the great composite order than this, and few generally less understood or successfully cultivated in British gardens. Perhaps the chief difficulty of all, and especially would-be cultivators of the plant, is the difficulty experienced in getting really good established plants to begin with. If such were more generally procurable the plant might with more frequency be found flowering in the best gardens in this country. One of the mistakes that has been made is that of planting in a warm sunny position, or even going to greater extremes still in the same direction. In all these, however, failure must sooner or later ensue. What the plant really needs in this respect is shade and moisture, the former in a measure that requires some qualification. For example, it is not so essential that the stems and growth generally shall be in the shade, but it is absolutely essential that the roots may be so protected that a cool and uniformly moist rooting medium be guaranteed. In this respect it is on a par with some Lilies that delight to send their heads of blossoms into the full light and warmth of day, yet prefer a cool and moist condition at the root. For this reason the *Rhododendron* bank has been frequently planted with Lilies, and a good measure of success the result. There is

no more fitting place in the garden for this lovely *Mutisia*, particularly where the *Rhododendrons* are well tended in the matter of summer watering, for this would exactly suit the growing season of the above plant, and enable it to spread itself over the heads of the shrubs, and in flower form a most pleasing picture. There is no fear of the growth being too abundant, as it is not in the nature of *Mutisias* to produce more than a few shoots each year. Yet these few shoots when strong produce a really good complement of striking blossoms, enough to satisfy the majority of those who succeed in growing the plant at all.

One of the finest plants I have seen near London will in some degree prove that the above position is not wholly essential to success. This plant was grown in the Pine-apple Nurseries, Maida Vale, scarcely one and a half miles from the Marble Arch, the position being a shady one from about 11.30 a.m. The plant was trained to a wall and planted out in one of many narrow borders there, beside the green-houses. Here it grew several feet high and produced many of the rich orange flower-heads that render it so striking. The ray florets are of considerable length till the time for recurring arrives, when they form themselves into an elegant as well as graceful flower. This plant may have been said to be a success, and for a London garden especially so. It was planted in peat and about a third loam, with sand in plenty, and was watered freely in dry weather. Another proof of the success of this example was the somewhat free manner in which suckers were produced, these being secured for stock. I believe this plant would not resent free supplies of moisture in summer, provided the drainage is perfect, which is more or less essential. Perhaps one of the best ways of making this handsome plant more generally known would be by an endeavour to obtain fresh seeds from the natural habitat of the plant, an item which our leading botanic gardens, through their directors, should be able to accomplish at will. So good a plant, too, is also worthy of special care, and seeds distributed to leading British nurserymen and others would doubtless receive the attention they deserve.

E. J.

Aster Amellus bessarubicus.—This is one of the few hardy flowers that do not bear the impress of the protracted heat and drought. Whilst many things have a dried-up and very miserable appearance, this *Starwort* is flowering as freely and looks as fresh as if the plants had not been subjected to such a severe trial during the last few weeks. A group of this *Starwort* planted some five years ago is a mass of bloom, although no manure or top-dressing of any kind has been applied from the time of planting. Hardy plants of such an enduring nature are very precious, especially if they come into flower at that time of year when in a general way tender things are liable to be injured by frost and rain. This must be a fine bee plant, for when in bloom the flowers are smothered with them and other insects. On two plants I counted four black admirals, six tortoise-shell, and one peacock butterflies, half-a-dozen species of humble bee, some of which I had never before seen, besides countless flies and bees innumerable.—BYFLEET.

Hardy Cyclamens.—Colonies of these in partly shady situations have a bright appearance at Wisley. They are grown on mounds considerably above the ground-level, so that good drainage is assured. The pure white variety of *Cyclamen hederifolium* is a dainty little flower, exquisite in form and wonderfully pure in colour, a flower that does not suffer by comparison with the choicest productions of our glasshouses. It was worthy of note that in the full sun and on a dry bank there was not a sign of life, and I shall be curious to

know how these plants behave by-and-by. I fancy they will only begin to bloom towards November, and that about February, weather permitting, they will be making a display. The charming flowers are followed by a beautiful leafage, which has wonderful powers of endurance. That leaves of such a succulent nature should be able to withstand the severe frosts of our winter is little short of marvellous. It is this power of resistance to inclement weather that renders them so precious for the outdoor garden in winter.—J. C., *Byfleet*.

LILIES.

THE statement made with respect to *L. Henryi* that in all but colour it is a counterpart of the old *L. speciosum* is not borne out by the appearance of plants in bloom at Wisley. The flowers of the two species, it is true, resemble each other in form and are of about the same dimensions, but in habit of growth the new-comer is much taller and the leaves are considerably smaller. It is, however, a fine and showy species, the orange blooms being very bright and effective, and will undoubtedly receive a hearty welcome from lovers of the genus. The stiff, wiry-looking stems and deep green leathery foliage would seem to indicate that it is possessed of a vigorous constitution. When it becomes more plentiful and can be planted in groups of a dozen or more bulbs it will have a fine appearance, and the fact of its blooming at the close of the summer naturally enhances its value. It certainly affords a fine contrast to *L. auratum* and *L. speciosum*, with which it should be associated. The value of the finer forms of *L. speciosum* for outdoor blooming is well illustrated at Oakwood just now, and one sees how superior the true Japanese cruentum, which Mr. Wilson considers to be identical with *Melpomene*, is to the Dutch varieties commonly grown in this country. Some of the flowers are very finely coloured, and I was surprised to note how well the plants had withstood the protracted heat and drought. It has been found desirable to move the bulbs of *L. auratum*, and one does not this year see flower-stems 10 feet high, with blooms proportionately numerous. Hundred of bulbs have been set out in newly-prepared beds, and although the plants are much dwarfed than one has been accustomed to see them at Wisley, they look remarkably well, the strongest bearing flowers as good as one generally sees on old-established plants. Some of the scarcer varieties, such as *platypetalum*, are flowering finely, but Mr. Wilson considers that a good form of the type is quite as good as these named expensive varieties. The fact is that the old *L. auratum* in its best form is so fine that there seems to be little or no possibility of improving it.

J. C. B.

Lobelia cardinalis.—No doubt a long time will elapse before the general public will know what the above plant really is, the common practice being to call every scarlet *Lobelia* by that name. The object of this note is to point out how exceedingly hardy it is. Two or three years ago I had a large bed of this in the open ground. The winter being a very dry one, and the position of the bed dry, every plant perished. At the same time three plants in pots were standing in 1 inch or 2 inches of water in a shallow tank. When the frost came these were gradually raised up out of the pots on columns of ice, into which they returned when the thaw came, and they were the only plants that survived, looking at the end of the winter as fresh as anything could look. Coming as they do from the cold Canadian bogs, all this was to be expected, and the moral is—plant this kind in the wettest swamp you have, and it will light up the spot with a red glow such as no other plant is capable of. All the syphilitica forms will thrive in the same situation.—T. SMITH, *Newry*.

Starworts naturalised.—Very few hardy perennials can be trusted to hold their own if left to contend unaided with our natural vegetation.

The stronger-habited forms of Starwort, however, are not only able to live under such conditions, but seem able to increase in bulk under treatment that would be fatal to many hardy flowers. There is at Oakwood a piece of ground on which the natural herbage has been allowed to have its own way. From a row of established plants hard by seeds have distributed themselves, and it is

Bocconia cordata.

curious to see how well the little seedlings have come along among some of the coarsest grasses that inhabit the British Isles, have at length pushed up and are blooming with delightful irregularity over an acre or more of ground. To my mind these miniature plants blooming among the grass offer a much more pleasing picture than the big lumpy specimens commonly seen in cultivation. These Starworts are in the true sense of the word naturalised, and if the ground is not disturbed their progeny will in all probability be found growing and blooming in a hundred years' time.—B.

Spanish Iris.—That the beautiful forms of Iris Niphium have taken a deep hold upon the flower-loving public there can be no doubt. Earlier to bloom than their relatives, the English Irises, they exhibit in addition a great variety of colour, such as beautiful shades of purple, blue, violet, and also delightful combinations of these, bronze, yellow, white, &c. As the bulbs are now being largely imported into this country, the time is favourable to press upon the attention of those who love their gardens the claims of the Spanish Iris. The lists of varieties receive accessions every year, because the Dutch florists are active in raising seedlings, and though it must not be supposed that every new introduction marks a real advance, yet there is a gain in variety, while many lovers of the flower delight in cultivating new varieties, as it is always interesting to watch the expanding blossoms of some new aspirant to favour. In planting it should be remembered that the Spanish Iris is impatient of stagnant moisture about its roots in autumn and winter. My neighbour grows his in a free and somewhat stony ground, where there is ample drainage, but he manures on the surface with rotten manure and leaf-mould, and when the plants are coming into bloom a little weak manure water is given twice a week. He grows the Irises among his dwarf Roses, with the result that they afford shelter from rough winds, as the stalks are brittle and

soon damaged. But it is a sunny position also, for this type of Iris appears to revel in sunshine. Plant as soon as the bulbs are received, and, having planted, leave them undisturbed. Top-dressings keep a nourishing soil about the bulbs, but if a weakly growth should indicate that the soil has become exhausted, then a new plantation should be made so as to secure renewed vigour and fineness of bloom.—R. D.

BOCCONIAS.

THE genus *Bocconia*, although consisting at the present day of five species, is only represented in gardens by two, namely, *Bocconia cordata* (Willd.), a very old plant, and *Bocconia microcarpa*, of quite recent introduction. The genus is founded on *B. frutescens*, of Mexican origin, whose introduction dates back to 1739. The stems of the plant are about 5 feet in height. As it needs, in winter at least, the temperature of the greenhouse, it is rarely to be found in cultivation, if it even exists at the present day.

BOCCONIA CORDATA is very well known and justly esteemed. It is a handsome plant some 6 feet or 7 feet in height. The best effect is obtained from isolated plants on the lawn and in large beds. It is a native of China, and was introduced by Sir George Stanton in 1795. In 1866, M. Ed. Andre described in the *Revue Horticole*, under the name of *Macleya yedoensis*, a plant of this race, of unknown origin, which was then well known in gardens as *M. japonica* and *M. yedoensis*, and was specially characterised by the absence of petals. This plant, which seems not to have continued in cultivation, may be regarded as a variety of *Bocconia cordata*. Within the last year or two M. Maurice de Vilmorin received from China another variety with flowers set with rose-coloured petals, but this has not yet become common. Both plants will be found described in most gardening books, and notably in the *Bon Jardinier*, the first under name *Macleya cordata* (R. Br.), the second as *Bocconia frutescens* (Linn.). The species *Macleya*, founded by Robert Brown, being no longer admitted by modern botanists, both plants are held to be species of *Bocconia*.

B. FERRUGINEA (Roelz.) has never been introduced into cultivation; and if the contrary is the case with *B. integrifolia* (Bonpl. and Kauth.) it has, nevertheless, remained so rare that only one work we know mentions it, and that very briefly. The fifth and last species,

B. MICROCARPA (Maxim.), was also obtained in China, in Eastern Se Tehuen, by the Abbé Farges, and was received by M. Maurice de Vilmorin some years since. Its stems are slightly unequal, the stature the same, and the form of its foliage does not materially differ from that of *B. cordata*, though with a much more glaucous and even bluish hue, and very dusty in the young shoots. Its inflorescences are borne in panicles, which are larger, more branching, and its berries are much smaller. *B. microcarpa* deserves a place before *B. cordata*, the only one in cultivation up to now. In addition to raising by seed, which should be done in the spring in pots in the open; it can be readily propagated by division, and if need be by division of the roots. Moreover it spreads enormously.—E. MOTTET, in *Revue Horticole*.

Physalis Franchetti.—This is one of the most striking and ornamental plants that have been added to the hardy plant garden for a long time, its value lying not merely in the fact of increased size in the richly-coloured calyces, but in its greater all-round attractiveness. One of the weak points of the old Winter Cherry (*P. Alkekengi*) is that at the moment the calyces attain perfection it is likely to completely lose its foliage, which it does in any case with the first touch of autumn frost, and while pretty enough in a group in the rock garden or other

place, produces a rather bare appearance from this cause. The above species, however, while being decidedly more ornamental in growth during summer, also attains a vigour and freedom of growth that go a long way to establish it as a first-class plant. In habit the plant is all one could desire, while in freedom of flowering and fruiting the plant is first-rate. Where large effective groups are required, the gardener will find this a most valuable and easily-grown perennial.

THE HYBRID CLEMATISES.

(Continued from page 271.)

3.—FLORIDEÆ.

THE hybrids of *C. florida* are never double at least I have never seen a double one with the exception of *C. bicolor*. The green-white flower of *C. florida alba plena* (Indian Atragene) is not a double flower in the proper sense of the term. Of the three Clematisses introduced from Japan by Siebold only *C. florida simplex* is the true specific type, the other two, *C. florida alba plena* (*Atragene indica*) and *C. florida bicolor*, being to all appearance rather forms or varieties of the type. It may be supposed that the hybrids of *C. florida* are very rare, and, in fact, in European gardens I only know of one, and that one obtained from seed of *C. Vitiella*. The plant in its carriage, its distinct foliage, its inflorescence, and flowers formed of six sepals presents all the characteristics of relationship with *C. florida simplex*, and ought rather to be called *C. florida simplex* than *C. Vitiella venosa*. It is one of the handsomest of hybrids, and the flowers, which are of fair size, are of a superb violet-purple, with veins of a brighter tint. The inflorescence is

Bocconia microcarpa.

axillary on single flower peduncles. I find in catalogues two varieties of *C. florida venosa*; one with larger flowers of a bright mauve, veined with white (*C. florida venosa grandiflora*, Lem.); the other with flowers perfect in

form, the edges of the sepals somewhat undulating and fimbriate (*C. florida venosa* violacea, Lem.). Although habitually sterile, *C. florida venosa* has been known to accidentally ripen seed, from which have resulted two new plants, *C. f. atro-violacea*, a very deep violet flower formed of five to six sepals, and *C. Viticella alba nova*. This latter Clematis, of which I have already spoken when dealing with the hybrids of *C. Viticella*, appears to me to have with *C. Iris* and *C. Mme. Moser* undoubted relationship with the florideæ.

4.—AZUREÆ.

This section is assuredly the one best adapted for hybridisation. Their short spring bloom lasting only through May and June allows of the perfect and early maturity of their feathery, waving, and spheroidal carpels. Japan, the country of their origin, has given us a sample of their cultivation in sending us at the same time as the species (*C. azurea*, Hort.) a certain number of single and double varieties. Among these a quite distinct form is *C. Sophia* with large notched sepals. From a lilac or azure purple the flowers pass to white, with sometimes white and sometimes purple stamens. Here I must correct an error which has found a place in all catalogues. The double or semi-double-flowered hybrid Clematises do not spring from the florideæ, but are invariably issue of the azureæ, in most cases producing seed, notably *C. Fortunei*, the semi-double flowers of which ripen their seed. The flowers are large, single, formed of six to eight sepals set on long axillary peduncles on the old wood. Spring is the time of bloom. But there are many other large-flowered hybrids, like *C. gigantea*, which preserve the inflorescence and the one-flowered peduncles of the azureæ; yet in spite of this, their downy buds, rosaceous corolla of six or eight sepals, and the continuous bloom have caused them to be classed as hybrids of *C. lanuginosa*. The hybrids of the azureæ are so numerous that I can only give here a very incomplete list.

C. AZUREA AMALIA, *LOUISA*, and *HELENA* were for the most part brought direct from Japan, where they are cultivated, with *C. Sophia*, *Sophia flore-pleno*, and *monstruosa*. To these I have to add

C. LOUISA FLORE-PLENO (Simon Louis), with white, lilac-edged flowers.

C. MALIA (Simon Louis).—Flowers dark blue, with brown anthers.

C. A. VIOLACEA and *C. A. ATRO-PURPUREA* are both varieties of *C. a. Helena*, obtained by Theodore Spræ, of Ghent (Belg. Hort., 1864).

The following varieties are often met with:—
C. WEITCH.—Flowers double, of fair size and bright blue. Introduced direct from Japan.

C. COUNTESS OF LOVELACE.—Double, blue-violet flower, the sepals regular and imbricated. In the second bloom the flowers are single, as happens often in the case of other double hybrids.

C. DUCHESS OF EDINBURGH (Jackman).—Double, white and strongly imbricated flowers, sweet scented, like those of *C. Fortunei*. It flowered for the first time in 1874.

C. LUCIE LEMOINE (Lem.).—A white, semi-double flower, ripening its seed well. It is one of the oldest and best known double kinds.

C. EXCELSIOR (Cripps).—Large semi-double flower, of a handsome blue colour, resembling Countess of Lovelace.

C. FAIR ROSAMOND (Jackman).—Early bloomer, the flowers large and rosy white.

C. LOUIS VAN HOUTTE.—Spring blooming, rosy white, semi-double flowers.

C. MME. MÉLINE (Christen).—Pure white, double and regularly imbricated flowers.

C. MARIE LOUISE LE BELE (Dr. le B.).—Large white flowers, each 8 inches to 10 inches wide. This is very free flowering.

C. JEANNE D'ARC (Dauvesse).—Large rosy white flowers.

C. AURELIANA (Dauvesse).—Large mauve-violet or red flower.

C. LADY CAROLINE NEVILL.—Early bloomer; colour pale blue with red veins.

C. RENÉ ALLÈGRET.—Double or semi-double, deep blue flower.

C. REGINA (Weitch).—Mauve.

C. LILACINA PLENA (Lem.).—Lilac, medium-sized, very double flowers.

C. INSIGNIS.—Very early, bloom lilac-violet, the nearest allied to the species (*azurea*, Hort.).

C. A. HYBRIDA ANDEGAVENSIS.—A handsome, vigorous hybrid, the result of crossing *C. azurea* and *C. lanuginosa*, which I have cultivated for twenty years. It came to me from Angers, where it bore the name of *lanuginosa foncè*. Although the buds are woolly, yet the pointed, oval, bright smooth leaves, and the flowers of a handsome dark blue, changing to a lighter shade, with their six-fluted sepals and their purple stamens, mark it as belonging to the section of the azureæ.

5.—LANUGINOSÆ.

In this last section I place those hybrids among the race which possess the largest flowers, the colour being light blue, mauve, carnation or white, and the sepals broad and recurved. The inflorescence is in bouquets, but frequently also on single-flowered peduncles. These often flower from June to September. The flowers are seldom double. The leaves are not as a rule woolly as in the true *lanuginosa*, but the buds are frequently more or less so, when the leaves are almost smooth.

C. LANUGINOSA PERFECTA (Froebel), a cross between *lanuginosa* and *hybrida splendida*, has six broad violet-mauve sepals.

C. LANUGINOSA SUPERBA.—Deep violet.

C. LANUGINOSA CANDIDA.—White and a continuous bloomer.

C. LANUGINOSA NIVEA (Lem.).—Pure white.

C. LAWSONIANA (And. Henry).—Lavender-blue, a spring bloomer, sepals as in *C. azurea*.

C. OTTO FROEBEL (Froebel).—Large rosy white flower.

C. MME. EMILE SORBET (Paillet).—Large buds, sepals numerous, of a violet-lilac colour, changing to bright lilac. 1878.

C. DUCHESS DE CAMBACÈRES (Paillet).—Flowers about 8 inches across; colour sky-blue.

C. GIGANTEA.—Rosy white, changing to pure white. Flower very large, formed of eight to ten sepals.

C. VILLE DE PARIS (Christen).—A cross between *Fair Rosamond* and *lanuginosa*. Very large flowers, formed of six to eight petals, white, changing to a fine rose colour.

C. LA FRANCE.—Obtained about the year 1886 by M. Gègu, of Angers, from *C. lanuginosa* × *C. Jackmani*. The buds are woolly, although the leaves are smooth. Flowers deep cobalt-blue and lozenge-shaped, sepals pointed with waving edges. A very handsome hybrid.

C. DOCTEUR BLANCHET (Boisselot).—A handsome rose-lilac.

C. REINE DES BLEUES (Boisselot).—A hybrid between *C. lanuginosa* and *C. Jackmani*.

C. BÉLISAIRE (Lem.).—A large flower of a lilac colour, changing to white.

C. EUGÈNE DELATTRE (Christen).—Lavender-blue, buds woolly.

C. MME. BOSELLI (Christen).—Flowers large, of a mauve shade.

C. MME. THIBAUT.—Inflorescence as in *C. lanuginosa*. Very abundant on bright blue or lilac flowers. This points to a relationship with the *C. Viticella*.

C. LADY BOVILL.—Bright or sky-blue. It is in bloom during July and August.

C. THE PRESIDENT.—A rich violet-blue-purple flower.

This incomplete list brings to a close what I have to say about hybrids or large-flowered Clematises. My essential aim was their classification in natural groups, based upon the botanic

characters of the different sections formed by the species.

A PARASITIC PLAGUE.

Unfortunately, these large-flowered hybrids are subject to the attacks of a mysterious disease, which is extending its ravages yearly, and against which there has been no contending so far. It is plainly a case of a new cryptogamic parasite, which, at any day, may bring about the sudden death of a plant, and not infrequently the destruction of plants in full flower and in the enjoyment of, to all appearance, the finest health. It is to be hoped that, with better knowledge of this fungus, it may be attacked with success and its ravages among Clematises put an end to.

CULTIVATION.

Generally speaking, the Clematises are not fastidious as to soil. It is none the less true that they prefer a well-drained soil and one that is rich in vegetable and leaf-mould. Some, like the *Atragenes* and *lanuginosa*, prefer a peat soil. But what is especially needed is a good aspect, and air and sun such as they find on bushes, trellises, and arbours. Cultivation on strong and moderately tall stakes is the simplest and most practicable, but it is not so artistic as the freedom of the large climbing species, *Vitalba* and *montana*, which from the summits of lofty trees form garlands, or droop in graceful wreaths towards the ground. As regards most of the Clematises, planting at the foot of the tree-stem is lost labour, because, generally, in that position they become sickly, do not flower, or flower badly. The best, and also the most picturesque, way to grow the Clematis is that of the Vine in Italy, which is attached to the young Elm or white Mulberry tree in such a manner that the tree, left with just sufficient branch and vegetation to keep it alive, serves as a support for the Vine, and receives from a borrowed luxuriance and ornament. In parks and large gardens every occasion should be sought to get rid of trees that have become inconvenient or give too much shade; but instead of rooting them up it is best to saw them off at about 7 feet or 9 feet from the ground, and allow them to put out a few branches to form living leaf-bearing supports for the Clematis. In selecting these, choose such as will give variety in colour and a long-continued season of bloom. In

PRUNING.

the Clematis the work should be done intelligently and in deference to the needs of each section. The *Viticellæ*, *Jackmani*, and *lanuginosa*, which bloom on the wood of the same year, can be cut back more or less, especially the two first, when periods of cold have gone by. With the florideæ, on the other hand, little pruning is permissible beyond cutting off the branches that flowered the preceding year and as much as may be found necessary, having regard to the growth, which is very forward and even continuous in mild winters. Last, azureæ ought not to be pruned till the blooms are over, but useless branches and seed-bearing peduncles ought to be removed.—DR. JULES LE BELE, in *Bulletin de la Société d'Horticulture de la Sarthe*.

Calceolarias.—It is not always these showy plants are satisfactory in the flower garden, disease often making sad havoc with them. Some gardeners have given them up on that account. I know it is thought that rich soil is necessary to ensure large, bushy, well-flowered plants, but I fancy they do better in a poor root-run and are less liable to disease. I am strengthened in this

opinion from the fact that in many amateurs' and cottagers' gardens round Norwich the plants do well and flower profusely. The soil, as a rule, is anything but rich, and growth in consequence more wiry than on plants growing in richer quarters and disease seldom met with.—J. C.

ROSE GARDEN.

SOME GOOD AUTUMN ROSES.

WHAT a wealth of variety the planter of the present day has to select from among the beautiful Tea, Hybrid Tea, Chinese, and Polyantha Roses. Many beds and borders that are now cumbered with common and garish bedding plants might be filled with these beautiful and perpetual-flowering Roses. Where is there any shrub so continuous in flowering as the Tea Rose and its congeners? Of course, such a season as the present has been an exceptionally trying one, but even this autumn, when the majority of the so-called Hybrid Perpetuals are losing their foliage, the truly perpetual kinds are yielding fair quantities of their delightfully tinted blossoms. A marked difference in the quantity of blossom produced is manifest where deep cultivation and judicious watering and mulching have been carried out, and I would impress upon all planters of these Roses the necessity of adopting measures to keep the plants in a growing condition. This can best be done by transplanting and also renovating the soil at intervals. I prefer beds of each variety even if the quantity of each does not exceed half a dozen plants. It may be said that every variety of the tribes mentioned has its own peculiar individuality in growth, and in my opinion a better effect is obtained when it is possible to give a bed to each kind. Now the Tea Rose, if pruned in a rational manner and not mutilated after the style of the exhibitors' plants, forms itself into a really graceful bush, differing greatly from the stiff, regular type of the Hybrid Perpetuals. Many of these beautiful Roses of the more vigorous habit of growth are peculiarly adapted for training in pillar form, and I would suggest beds of such kinds as *Gustave Regis*, *Belle Lyonnaise*, *Mme. Chauvry*, *Bouquet d'Or*, &c., at intervals where more elevated groups seem desirable. I would plant such beds in preference to the more formal standards, although these latter have their uses. Imagine a fine bed of *Mme. Lambert*, the bushes 4 feet to 5 feet high, as I have seen them, covered with lovely rosy pink blossoms in close proximity to a bed of *Hydrangea paniculata grandiflora*, or a bed of the ever-blooming *Camoens* (a Rose almost as persistent in flowering as the common pink *Monthly* and far more effective) in close vicinity to a small group of *Hypericum Moserianum*. The lovely azure blue of *Clematis Davidiana* would certainly be brought into greater prominence if a bed of the creamy yellow *Mme. Hoste* or the equally lovely *Enchantress* were in near vicinity to it. These are only a few of the many beautiful combinations possible between flowering shrubs and Roses, and although large masses are very effective, beds of the smallest size produce in proportion a beautiful effect. For this purpose I might mention as being excellent growers the charming *Anna Ollivier*, with its lovely long fawn-coloured buds, the richly coloured *Papa Gontier*, the glowing crimson *Marquise de Salisbury*, the beautifully formed rosy pink *Marie d'Orleans*, probably the best of the *Riviera* Roses, and the charming semi-double, large-petalled *G. Nabonmand*, as delicate in hue

as a *Sea Anemone*. One must not forget to notice the ever-popular *Marie van Houtte* with its carmine-margined, creamy blossoms, or the almost white, very double *Hon. Edith Gifford*, so grand in the early summer with its ruby foliage. Then there is *Caroline Testout*, probably the best deep pink for massing, a truly splendid garden Rose; and yet another rich pink is *Mrs. W. J. Grant*, equally lovely and showy for this purpose. *Mme. Abel Chatenay* has a great claim for admiration by reason of its exquisite fawn-pink blossoms and its vigorous growth that so well adapts it for pillar or bush form. The white *La France* and, of course, the old pink variety are so well known as to require no commendation here; sufficient it is to say that they remain two very useful kinds, and will always find a place by reason of their delicious fragrance. Two other well-known varieties are *Grace Darling* and *Viscountess Folkestone*, and even the smallest garden should possess them. The list seems inexhaustible, but one cannot conclude without naming *Mme. Pernet-Ducher*, so lovely in bud, which is creamy yellow, and expanded blossoms white, or *Grand Duc de Luxembourg*, that may be called a dark-coloured *Viscountess Folkestone*, and is admired by everyone who sees it, although as a novelty it seemed to escape the notice of most rosarians. A Rose that has made remarkable advance in popularity is *Kaiserin Augusta Victoria*; its excellent upright habit fits it admirably for the purpose in view, and its style of flower reminds one of a perfected *Devoniensis*. For a rich mass of apricot colour, no better variety exists than *Mme. Charles*, certainly the best of the *Mme. Falcot* tribe, and in good scarlet-crimsons we have *Princesse de Sagan* and *Francis Dubricul*. The *Queen or Souv. de S. A. Princee* and *Sombrioul* are two grand pure white varieties, free and showy, and equally so are *Souvenir du President Carnot*, that has a blossom like a refined *Souv. de la Malmaison*, and *Mme. Carnot*, a splendid loose-petalled white Tea Rose. Three exquisite novelties that cannot be omitted are *Empress Alexandra of Russia*, distinct in its bronzy blossoms; *Mme. Jules Grolez*, a Rose of delightful colour, best described as a brilliant salmon-pink, with charmingly pointed petals; and last, but not least, *Souvenir de Catherine Guillot*, certainly the best of the *Ideal* type of Rose. All the above varieties are really excellent autumnals, and it is at this period of the year that beds of Roses seem extra valuable.

As I mentioned the Chinese and Polyantha tribes as useful allies to the Teas and Hybrid Teas, it may be admissible if I enumerate one or two of the best of them. Of the Chinese the most popular is certainly *Mme. Laurette Messimy*, possibly because its more lovely offspring, *Mme. Eugène Resal*, is not yet so well known. Another beauty is *Queen Mab*, with delicious apricot-coloured buds and splendid in constitution. Of older sorts, *Cramoisi Supérieur* is the most vivid of scarlet-crimsons, and *Fabvier*, if not so double, is a valuable rich crimson variety. *Duke of York*, a more recent introduction, is a charming Rose and always supplies quantities of highly-coloured *Homère*-like buds. *Mrs. Bosanquet* is not yet surpassed as a flesh-tinted variety, and of course the old blush-pink is a most excellent kind, but perhaps more fitted to form hedges or to be massed by carriage drives. In the Polyantha tribe we have Roses that lend themselves particularly to grouping, their growth being so dwarf, compact and uniform. A splendid white is *Anna Marie de Montravel*, producing a perfect sheet of bloom and most brilliant in its purity. *Gloire*

des Polyantha (rosy pink), *Perle d'Or* (apricot) and *Perle des Rouges* (crimson) are all excellent kinds for the purpose in view.—PULLOVELL.

— A great many of our popular Roses have been blossoming with great freedom this autumn, and for several weeks past I have been able to gather bunches of beautiful fresh blooms almost daily. As a rule Roses generally bear a good crop of blossoms in the autumn, but this season they have surpassed themselves. It is certainly very unusual to see Rose bushes covered with blooms in various stages of development at this time of the year, and yet such has been the case here of late. In many cases better developed and far more perfect blooms, even if smaller, have been produced than earlier in the year or during the Rose season proper. *La Franco* has been a notable example in this respect; in fact, one large-headed standard in particular was carrying as many flowers a few days ago as in the early part of June. *Kaiserin Friedrich* has also produced a good crop of its coppery yellow flowers, and *Reine Olga de Wurtemberg* the same. *Lamarque* on a wall has given a fine lot of its beautiful chaste flowers, and a *Niphotos* hard by has also bloomed freely, while the hybrid *rugosa* *Mme. G. Bruant* has again been clothed with a plentiful display of its pretty semi-double flowers. Among the Bourbons, *Souvenir de la Malmaison* and *Queen of Bourbons* have been beautiful, the shell-like petals and pretty flesh colour of the latter being remarkably handsome. The former generally produces more symmetrically-shaped blooms in the autumn than in early summer, and this season has been no exception to the rule. Among Tea Roses, many of the varieties blossom well in the autumn, and of these none is so free-flowering as *Mme. Lambert*, which is seldom out of bloom, and from the whole class a good supply is generally maintained until frost cuts them off. Among Hybrid Perpetuals, quite a large number have blossomed very freely. Among these, *Ulrich Brunner*, *E. Morren*, *Anna Alexicoff*, *Senateur Vaisse*, *Mme. S. Rodocanachi*, *Bessie Johnson*, *Mrs. J. Laing*, *Dr. Andry*, and *General Jacqueminot* call for special mention. The blooms of all these are of course smaller, but they are perfect in form. The colours, as is usually the case in the autumn, are perfect and the perfume of the scented varieties delicious. The pretty *Polyantha* *Roses Gloire des Polyantha* and *Anna Marie de Montravel* are very charming, and it is but seldom that they bloom here in such profusion twice in one season. The old *Monthly China* Rose will continue for some few weeks yet to produce an abundance of its charming sweet-scented flowers, which if cut just before they are half expanded last several days in water. Hot weather setting in as it did, before the Rose season proper was past, shortened the season considerably, and the blooms were burnt before fully expanded. This profuse autumn flowering is on that account all the more welcome.—A. W., *Stoke Edith, Hertford*.

— What a glorious time we are having here amongst the autumnal Roses! Some of the first to flower very early in spring (I am speaking of Roses left to take care of themselves roughly outside) are now the best. *Mrs. W. J. Grant*, *Belle Siebrecht*, *Dr. Grill*, *Princess May*, *Souv. de la Malmaison*, *Reine Marie Henriette*, *Jaune Desprez*, *Ophir*, *Ophir* (the last the best with me, for a bud almost perpetual flowering), *Homère* (very free and hardy), *Marie van Houtte*, and *Mrs. Paul* are excellent. *Gloire de Margottin* against a wall is most dazzling. This beats, it possibly, *Paul's Carmine Pillar* and *Paul's* grand *Single Scarlet* for colour, and flowers late and early. *Wm. Allen Richardson* is putting out flowers of exceptionally good colour. *Victor Verdier*, *Fisher Holmes*, and *Senateur Vaisse* are giving lovely buds. *Mrs. John Laing* is flowering at the ends of long-shoots, with *Aimée Vibert* and many others. Sweet Peas, too, are flowering splendidly.—GEORGE BOLAS.

* * * A beautiful gathering of Roses, many of the blooms being equal to those we are accus-

omed to see in the height of the season. The colours, too, are very brilliant.—Ed.

Rose Etienne Levet.—I was very much surprised to find "P." describing this Rose as having a dwarf and stumpy growth, for I have always found it to be most robust, and the National Rose Society's catalogue describes it as robust. In truth it is one of those Roses which we are constantly warned not to prune hard because of its tendency to make strong shoots, and so lose its free-flowering habit. It is one of those large shell-petalled Roses that are much in favour with exhibitors, and for the same reason is always an attractive Rose in the garden, but my experience of it is certainly not that of your correspondent.—1).

Roses at St. James', Malvern.—In these gardens, on sharp slopes on the lofty hillside. Roses of all descriptions, and especially Teas, do wonderfully well. The soil is of pulverised cyanite, the material of which the grand range of Malvern Hills is composed. It does not look at all like a Rose soil, but trenched and manured it suits them well. Roses are planted on the slopes here by hundreds, and almost every description of garden Rose, besides Teas, is found. When I saw the gardens on September 13 the latter plants were all blooming profusely. The Hybrid Perpetuals, fine as they may be in summer, were not in it for a moment with the beautiful branching Teas. On one slope are numerous plants of the newer French Hybrid Teas, but these seem poor things when compared with the best Teas of commerce. No doubt the elevated position and sharp slope of the soil suit the plants well and render them hardy. A remarkable Rose for covering banks is *Rosa Wichuriana*. This, whilst having in growth and foliage some resemblance to the Banksian, yet literally creeps on the ground like Ivy and does not rise above 12 inches. During the summer and autumn it blooms profusely. The flowers, borne in small clusters, are single and pure white. It would make a grand plant to face and bind railway embankments. Crimson Rambler will next year be a huge umbrella-like mass. Very fine on fences are Longworth Rambler and Gloire de Dijon, and many free growers profusely cover banks. *Rosa rugosa* forms a hedge 200 yards long in one portion of the grounds; indeed, Roses crop up everywhere and in luxuriant condition.—A. D.

GARDEN FLORA.

PLATE 1191.

THE SPECIES OF AZALEA.

(WITH A COLOURED PLATE OF RHODODENDRON VASEYI.*)

WHILST it is convenient to speak of Azaleas as distinct from Rhododendrons, it has long been admitted that no real distinctive line can be drawn between the two. They were originally kept apart on the strength of the deciduous foliage and five stamens of the Azaleas, but when species like *A. indica* and *A. ledifolia* were found with evergreen foliage, and other species with ten or more stamens to each flower, the only logical course was to unite them to Rhododendron. The species now figured is one of the Azalea group. This section of the genus is most abundantly represented in North-eastern Asia (China, Japan, Manchuria, &c.), to which region the evergreen species are confined. A beautiful group of some seven species comes from North America, whilst in Europe we have but one species (*Rhod. flavum* or *Azalea pontica*). The American species are amongst the most attractive of hardy shrubs, but they are surpassed by the numerous varieties that have been obtained

* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Goffart.

from them by hybridisation and selection, which are often known as Ghent Azaleas. These, again, have been crossed with *R. flavum* and sinense, the whole constituting what is in some respects, the most beautiful group of deciduous shrubs that can be cultivated in this country. The charm of these Azaleas consists in their marvellous wealth of blossom, in the rich and glowing, often tender and exquisite, shades of colour, and in the fragrance which most of them possess. The colours range from pure white and yellow to bright orange-scarlet and rosy-purple. In a word, no garden is complete without them. In the following notes only the wild types are discussed. Some of these, whilst lacking the size of flower and variety of colour seen in the hybrids, are quite as fine seen in the

from seed, and although the hybrids do not come true, it is interesting and useful work to raise them from seed, selecting this from the finest varieties. Whilst the seedlings vary considerably, they retain in a great measure the characteristics of the parent plants; some, indeed, are likely to be superior to them.

AMERICAN SPECIES.

RHODODENDRON ARBORESCENS.—But little is known of this Azalea in gardens at the present time; it is one of the rarest of the American species. It is a shrub, sometimes 15 feet to 20 feet high, with blunt lustrous green leaves that are quite smooth on both surfaces, but have bristly hairs on the margins. The flowers are white or faintly rose-coloured, each one 2 inches to 2½ inches across, with the corolla slightly clammy

Hardy Azaleas in a vase.

mass, and those that are fragrant are not surpassed in this respect by any of the hybrids. Others, again, are quite distinct from any of the hybrids both in flower and in the season of blooming. They are of easy cultivation, and can be grown in any moist soil either of a peaty or loamy nature that is free from lime. They are benefited by an annual mulching of rotted manure, more especially during dry seasons such as we have lately experienced. A freer growth and a better setting of bloom are secured if the seed-vessels are removed as soon as the flowers are past. This is a tedious job, but worth doing. The named hybrids are usually propagated by grafting on stocks of *R. flavum*, necessitating, unfortunately, a constant watch for suckers. The species here mentioned should be raised

They are charmingly fragrant and their beauty is enhanced by their bright scarlet stamens and pistil. It is a native of the mountainous region from Pennsylvania to South Carolina and Tennessee, and is especially abundant on the foot-hills of the high mountains of North Carolina. It is figured in *Garden and Forest* for 1888, and is there stated to have first been made known to botanists by Pursh in 1816. He had found it in the mountains of Pennsylvania and in Bartram's garden at Philadelphia. John Bartram, therefore, was the real discoverer. It was introduced to Britain in 1818. Prof. Sargent notes that the leaves in drying give off a perfume like that of new-mown grass, a peculiarity not noticed in other Azaleas.

R. CALENDULACEUM.—Some of the most brilliantly coloured of the Ghent Azaleas, especially those with orange-red flowers, owe their beauty

in a great measure to this species. In its pure form, however, it has become very rare in our gardens. It is a shrub probably 8 feet to 10 feet high. The leaves are hairy on both surfaces. The flowers appear before the leaves and are of a brilliant orange colour, and are, perhaps, the most beautiful of any of the American types, although they have no fragrance. The tube of the corolla is shorter than the lobes, this being one of the distinguishing characters of the species. It is a native of the Eastern United States, and extends from Pennsylvania to Georgia. It was in the latter State that it was discovered by the elder Bartram in 1774. It was introduced to this country by Mr. Lyon in 1806. The following is Bartram's description of his first sight of this Azalea in flower: "I saw the blossoms covering plants on the hillsides in such incredible profusion, that, suddenly opening to view from deep shade, I was alarmed by the apprehension of the hill being on fire."

R. NUDIFLORUM (the Pinxter Flower).—Like the preceding species, this is one of the North

American Azaleas, from which the Ghent Azaleas have been largely derived. It has an extensive distribution, and spreads from Canada as far to the south as Florida and Texas. Peter Collinson was the first to introduce it, in 1734. Its leaves are downy beneath, and the tube of the corolla is scarcely longer than the large lobes. The flowers vary very much in colour. In what may be considered the type they are pink, but the numerous forms have them of every gradation of red, from pink to scarlet and purple, some being striped or variegated. Most of the parti coloured Ghent Azaleas owe their origin more or less to this species.

R. OCCIDENTALE.—Both Douglas and Hartweg gathered specimens of this Azalea in Western North America when collecting for the Horticultural Society in the earlier decades of this century, but Wm. Lobb seems to have been the first to send seeds home. This would probably be in the early fifties. In spite of the more than forty years that have passed since it was introduced, this Azalea has never received until quite lately very much notice. Its real merits do not seem to have been known, and even Lindley in 1857 pronounced it to be "of little value." It is not only a beautiful shrub, but it possesses the additional merit of flowering for some weeks after the great Azalea time is past. Our largest plants are about 6 feet high, bushy and well furnished with glossy green leaves, each 2 inches to 4 inches long. They commence to flower in early June and continue well into July, and, unlike the majority of these Azaleas, the blossoms are accompanied by abundant foliage. They are each about 3 inches across and of a pure white, with a blotch of pale yellow on the upper side. Not their least charming characteristic is the sweet and powerful fragrance. For some years past Mr. Waterer, of Knap Hill, has been crossing it with the earlier flowering varieties, and has succeeded in uniting some of the rich colour of the latter with the late-flowering character of this species. It is the only Azalea found to the west of the Rocky Mountains, and inhabits woody districts, generally near streams, almost throughout the whole length of California.

Rhododendron (Azalea) sinense.

R. RHODORA (*Rhodora canadensis*).—This species was introduced by Sir Joseph Banks in 1757, and for a long time was considered to be generically distinct from the Azaleas and Rhododendrons, being known then as *Rhodora canadensis*. The character on which its generic rank was founded

was the peculiar arrangement of the corolla. This is two-lipped, the one lip consisting of two narrow, nearly or quite distinct petals, the other of three shallow, rounded lobes. The flower is $1\frac{1}{2}$ inches across and of a bright rosy purple. This shrub is dwarf and does not grow more than 3 feet or 4 feet in height; the leaves are more or less downy and glaucous beneath, and do not appear till the flowers are past. It is a native of Canada and Newfoundland southwards to the mountains of Pennsylvania, and frequents moist or boggy places. The plant is perfectly hardy and blooms freely; it is worth growing for its early blossoms, which are of a colour not frequent in shrubs flowering in early April, when this is in bloom.

R. VASEYI.—This is one of the most promising shrubs introduced from North America in recent years. It is a native of the hills of North Carolina, where it is described as growing into huge bushes 15 feet high. The leaves, which do not appear till after the flowers, are each from $1\frac{1}{2}$ inches to 3 inches long. The flowers are crowded on trusses after the manner of the other American Azaleas, and on first opening are of a pale pink, but they lose the slight tinge of colour and become almost pure white after a few days. The three upper petals are spotted with reddish brown, and the whole flower is about $1\frac{1}{2}$ inches across. It appears rather remarkable that so fine and showy a plant as this Azalea should have been so late in reaching cultivation, for, although a native of so long settled a country as North Carolina, it was not introduced into this country till within the last ten or twelve years. It is perfectly hardy, and flowers freely when two or three years old. Some of the seedlings raised in this country have blooms that are pure white on first opening. Its flowering season is late April and early May, and its beauty at that season when scarcely any of the Azaleas are in bloom may be judged by Mr. Moon's charming picture.

R. VISCOSUM (the white Swamp Honeysuckle).—This species is the latest flowering of the deciduous Azaleas, and is one of the most pleasing shrubs blooming in July and August. Its flowers,

like those of the Old World *R. flavum*, are clammy, and much more so than those of any other of the American species. They are smaller than those of most of the Azaleas, of a pinkish white, and delightfully fragrant. It has been hybridised with other species, and the progeny has flowers white, pink, rose-coloured, &c.; in fact, most of the hybrid Azaleas that have clammy flowers with no yellow in them are of the viscosum strain. (The viscid, yellow-flowered Azaleas are of the flavum breed.) The leaves of *R. viscosum* are each $1\frac{1}{2}$ inches to 2 inches long, green both above and below, and smooth except for the margins and the midrib, which are set with bristly hairs. In a wild state it extends from Canada to the Southern United States, growing in moist places or swamps, and attaining from 3 feet to 10 feet in height. It was introduced in 1734.

R. V. VAR. GLAUCUM has been by some authorities made a species. The typical form is very distinct from *R. viscosum* because of the blue-white under-surface of the leaves. But one may find plants showing every intermediate stage of glaucousness up to the ordinary green of viscosum. The flowers are white, viscid as in the type, and also charmingly fragrant. Introduced in 1734.

EUROPEAN.

R. FLAVUM (*Azalea pontica*).—This species is a native of the Canean region, the shores of the Black Sea, &c., and is the only Azalea indigenous to Europe. With the exception of a few varieties of the *sinensis* (or *mollis*) breed, all the pure yellow Azaleas have originated from this species, and they are well known to constitute one of the most beautiful groups of the family. The species has, of course, been crossed and recrossed with the American ones, and is one of the chief sources whence the hybrid Azaleas of gardens have been derived. One character that distinguishes it and its progeny is the clamminess of the flower-stalks. It is a very vigorous plant, with large hairy leaves, and grows 8 feet to 10 feet high. In the type the flowers are bright yellow and very abundant, and their fragrance is very delightful. In flower they are beautiful, but are, of course, surpassed in beauty by the fine yellow varieties raised by the Waterers and others. It was introduced by Mr. Anthony Hove in 1793. Honey collected by bees from its flowers is stated to have narcotic properties.

ASIATIC.

R. INDICUM.—The common greenhouse plant known as *Azalea indica* has in some of its forms

Rhododendron (Azalea) indicum.

proved to be hardy in the milder parts of Britain. In the Cornish gardens one may see enormous bushes of it, and even as far north as London the wild Japanese type recently collected by Professor Sargent is hardy, and still more so is the well-known var. *amenum*. The latter is, in fact, a more striking and beautiful shrub out of doors than it is under glass, its flowers being of a brighter colour and its habit more compact. It

has been grown outside at Kew for some years past, and for certain places proves to be a really useful evergreen. It is quite distinct in appearance from any other hardy evergreen, and has that peculiar habit of sending out flat, horizontal branches which we have come to consider essentially Japanese, perhaps because the artists of that country are so fond of drawing plants with that character or of endowing their imaginary ones with it. The leaves grow very small out of doors, but they are of a deeper and more lustrous green. Plants outside flower later, of course, than they do under glass, and are at their best, as a rule, about the middle of May. On healthy plants the flowers completely hide the foliage, and although smaller than we are accustomed to see them in the greenhouse, they lose in the open air a good deal of that magenta-purple shade which is objectionable to many people. The flowers have the curious character known to gardeners as "hose-in-hose"; it is as if one flower were growing out of the centre of another. This is due to the calyx being like the petals in size and colour. This *Azalea* is slow-growing, but in many positions this is a valuable characteristic. If planted in beds or groups it saves the labour of frequent thinning, and allows of Lilies or other bulbous plants being cultivated between the plants. In positions where only a low growth is wanted it saves the hard annual cropping that such things as Laurels and *Rhododendron ponticum* have to undergo.

R. l. var. obtusum is a beautiful shrub, probably hardy. It has not the hose-in-hose flowers of *amenum*, but it has them of a much brighter and purer red. Some nice plants were shown in flower at the last Temple show. Fortune found this shrub in a garden at Shanghai and introduced it into England in 1846. A form with white flowers is also cultivated.

The choicer garden sorts of *Azalea indica* are undoubtedly too tender for outdoor cultivation here.

R. LEDIFOLIUM.—Although certainly hardy in the home counties and long known in our gardens (having been introduced from China by Mr. Brookes in 1819), this evergreen *Azalea* has been but little planted out of doors. It is both an interesting and a pretty shrub, nearest related to *R. indicum*. It has very hairy leaves and branches, the latter being usually stiff and erect, and the former not glossy, as in *indicum*. The flowers are generally borne in threes and are pure white and fragrant. The calyx lobes are glandular and viscid. The species is, therefore, readily distinguishable from *indicum*, the only species with which it is likely to be confounded. The latter has a looser, more twiggy growth, much less hairy foliage, and the calyx is not viscid. With regard to its native country, it is, according to Franchet, cultivated, but scarcely wild, in Japan, though Marie collected it on the Fusiyama Mountain. No undoubtedly wild specimens are recorded for it in China, and although a specimen so named is in the Kew Herbarium from the Soul Mountains of Corea, it is doubtful if that be the true thing. This matter, therefore, is not definitely settled.

R. LINEARIFOLIUM.—Although one of the least showy of the *Azaleas*, this species is one of the most striking and distinct. It bears no resemblance to any other species in cultivation. The branches have the same tendency to grow in flat, horizontal tiers that can so frequently be noticed in Japanese shrubs. The leaves are remarkably distinct in shape, being quite linear, measuring 2 inches to 3 inches in length, and only about one quarter of an inch in width at the broadest part. These leaves are crowded at the ends of the twigs and are thickly covered with hairs. The flower is as distinct as the leaf. The corolla has five petals that have the same linear shape as the leaves; they are $1\frac{1}{2}$ inches long and the colour is a bright rosy blue. Hitherto it has usually been grown in the greenhouse, where it flowers during the first three months of the year. Except in large collections, however, it is scarcely worth a place under glass, where so many finer varieties

can be grown, but it has proved hardy in a rather sheltered spot at Kew, and out of doors is certainly worth growing for its curious and interesting appearance. It was introduced from Japan by Messrs. Standish, and flowered with them for the first time in February, 1869.

R. RHOMBICUM.—There is a fine plant of this species in the *Azalea* garden at Kew which is now 5 feet high and which flowers very beautifully every year towards the middle or end of April. It has been in its present position many years and has been mentioned in the horticultural press many times. Still, the species remains very rare, and this plant is probably the only one in the country so large. It is, however, being raised by nurserymen, and I noticed a nice stock of young plants at Messrs. Veitch's nursery at Coombe Wood some time ago. It is a native of Japan, and was first found in the forests on the mountains of Nippon. Its leaves have the lozenge shape indicated by the specific name, and they are about 2 inches long. When quite young they are prettily tinged with purple, and after turning a dark green they assume once more a purple tinge before falling in autumn. The flowers are each $2\frac{1}{2}$ inches in diameter and of a very striking blue-purple colour, quite different from that of any other hardy *Azalea*. To those who may be raising this plant from seed it may be mentioned that the seedlings are tender. The past two winters have been so mild that young plants have not suffered at all from cold, but in ordinarily severe winters protection of some kind is needed. Such material as Bracken, Spruce branches, or even dry leaves make a good covering whilst the hardest weather continues. When once the plants have formed a sturdy woody base they are safe. The old plant at Kew is never protected, but it has never been affected by even the hardest winters.

R. SCHLIPPENBACHII.—This is undoubtedly one of the most beautiful shrubs that have been introduced during the last few years. It was collected by Oldham as long ago as 1863 on one of the islands near Corea (Herschel Island); afterwards it was discovered in Manchuria by the Baron Schlippenbach, after whom it is named and from whose material it was first described by Maximowicz. But the credit of its introduction to cultivation here is due to Mr. J. H. Veitch, who sent it from Japan five or six years ago. There is a coloured plate of it in THE GARDEN for July 28, 1894. It is a shrub, growing, it is said, from 3 feet to 5 feet high. Its leaves are very distinct; they are borne in a whorl near the end of the shoot, each leaf from 2 inches to 4 inches long, obovate, and hairy when young. The flower-stalks and calyx-lobes also are hairy. The flowers open fully, are $3\frac{1}{2}$ inches across, and of a lovely shade of soft rose, the upper petals prettily spotted at the base with reddish-brown. It flowers in April and May. In the milder parts of the country it is likely to prove a very beautiful shrub. Near London I am not yet able to speak favourably of it when grown out-of-doors. It appears to be extremely susceptible to injury by spring frosts, the young growths having been out off sometimes twice in one season. Like many Manchurian plants in cultivation here, it may be perfectly capable of bearing our hardest winters, but yet never able to do itself justice because of the habit of starting so early into growth.

R. SINENSE (Azalea mollis).—Perhaps of all the deciduous *Azaleas* this is the most charming to the eye, its flowers being larger than those of the American species, and their varied hues being of a peculiarly soft and delicate beauty. They lack, however, the charm of fragrance. The species is a native of China and of the alpine regions of Japan. It was first introduced by Loddiges in 1823, and again by Fortune in 1845. The young branches, the leaves, and the flower-stalks are all more or less clothed with hairs. The flowers appear during early May, and are typically of an orange colour suffused with red, but they vary from pale yellow to numerous shades of rose and salmon colours. Whilst the shrubs themselves are quite hardy, the flowers are frequently injured by late frosts, especially in exposed positions.

In habit the plants are more compact and rounded than either *flavum* or the hybrid sorts. Many catalogues now advertise crosses between this plant and "*Azalea mollis*"; this is rather absurd, for they are, of course, the same thing. Whatever the origin of the varieties referred to may be, they are certainly very beautiful. This was conclusively shown by the specimens exhibited at the last Temple show by a continental firm. W. J. BEAN.

Arboretum, Kew.

THE WEEK'S WORK.

KITCHEN GARDEN.

EARLY WINTER TOMATOES.—The weather has been favourable for these plants, fire-heat not being needed up to now. The growths are strong and the fruits are setting freely. At the same time it is well to keep the roots active by giving food in small quantities now plenty of fruits are set. Plants with a small root-run with shortening days and less sun-heat will need assistance. I grow the winter Tomatoes in borders and pots, the latter for latest supplies. These will now need more food than those in borders. In the borders only a very small root space is allowed, and it is surprising what strong growths are made in a few inches of soil. It may be asked, why grow at all in borders? My reason is because of the labour at the time of planting, as to pot a large number takes time, and having a good number of low pits when Melons are cleared, the Tomatoes follow and give little trouble, doing well in the old Melon soil. Deep rooting is avoided, as the plants are placed over slates with a limited quantity of soil. Owing to the unusual warmth of the time of year, the plants are more forward than usual and a later set of fruit will be needed. This is not at all difficult with plants in borders, as with fine weather they continue growing and set fruit further up the stem. Once the fruits are swelling there is no difficulty whatever in finishing the crop. To assist the fruits at this date, feeding will be necessary. It will also be advisable to stop all later growths, and where the plants are well set with fruits there need be little fear of gross foliage. It may be well to top-dress, using compost that will quickly benefit the plants. I use loam, bone-meal and wood ashes, which are soon laid hold of by the roots, at the same time giving occasional waterings of liquid manure or soot water. With plenty of air the food given is soon absorbed by the plants. The plants, being grown near the roof as single cordons, get all the light possible and there is ample ventilation. Indeed, till the latter part of September, owing to the heat and drought, the top sashes were entirely removed, this assisting the fruits to set. Up to that date no fire-heat at all was employed. With cooler nights there is now need of warmth in the pipes; at the same time the house is not closed. Should the plants be at all gross, omit manures and give ample ventilation, keeping the foliage thin and securing an early set. I advise manures where the roots are under command, and with plants in rather small pots it is necessary to feed when there is a goodly number of fruit set. Many growers do not trouble about late Tomatoes, as they are difficult to set. This is so if the plants are late. So far I have never been able to set Tomatoes in quantity after November comes in.

EARLY SPRING TOMATOES.—These I noted the importance of some time ago and detailed their culture. By having healthy plants now to place in warmth early in the year, there is no great difficulty in getting good fruit in April at a time Tomatoes are scarce. The plants up to now have been grown as hardy as possible, having been plunged in ashes in the open or stood in cold frames with the sashes removed. With colder nights they are now housed on shelves close to the glass to get a sturdy growth. It may be necessary to give the early fruiters a shift. Only a small one should be given just to keep the plants

moving. I prefer repotting earlier, as the plants need careful watering. They winter well in 6-inch pots, and if the plants are well rooted it is an easy matter to give soot-water or weak liquid manure. Should white fly be at all troublesome, it may be necessary to fumigate two or three nights in succession. Plants raised thus are preferable to those struck from cuttings or raised from seed sown late in the year. I fruit these plants in 8-inch or 10-inch pots, according to their vigour at the time of final repotting. The fruits usually ripen at the end of March or early in April, whereas with later sown seedlings ripening takes much longer. Let me warn those who have good plants not to be too eager to get fruit. Early in the new year is a good time to start, keeping the plants cool till that date, as I find it impossible to set Tomatoes till January is well advanced.

CAULIFLOWERS.—In the southern parts of the country, owing to heat and drought, the early autumn Cauliflowers have had a bad time of it, heat and drought having sadly crippled the crop. For the past few weeks I have been obliged to keep a boy to clear these and the Brassicas from caterpillars. So far by mulching I saved a goodly portion of the latest lot of Autumn Giant, and this year I have found spent Mushroom manure invaluable for the purpose, this conserving the moisture and keeping the roots active. Those who planted late will feel the effects of the weather more severely, and there will, I fear, be a dearth of good winter vegetables owing to the above causes. In heavy soil much may be done by frequently hoeing the surface over lightly. This fills up the cracks and assists root action. The seedlings raised in August will be more valuable than usual owing to other vegetables being scarce. If the seedlings are unduly crowding each other, it will be well to thin out the largest. These may be transplanted rather close under a wall or where east winds will not reach them. It is yet full early to pot up for the spring planting, but I would not delay the work if the plants are large enough. I pot some hundreds into 4½-inch pots and others into 3-inch pots. If the winter is a severe one, it is an easy matter to plant them out in frames or pot on to get early heads before those in the open turn in. Grow these plants as cool as possible from this date. I plunge in ashes a large portion of the potted plants, and in severe weather they are protected by spare sashes and dry Bracken or litter. In potting up use a rather stiff loam. I add a little mortar rubble and pot as firmly as possible. Avoid rich soil or manures, these causing a soft growth, readily injured by frost. The ground for the plants put out under hand-glasses should now be prepared, and as Cauliflowers to do well need ample food, well-decayed manure should not be omitted. It is well if possible to give change of quarters. I am aware it is not an easy matter to get sheltered corners every year, but if the plants are always in one place they club badly.

MUSHROOMS.—This is an important crop now. I have previously noted the importance of an equable temperature through the winter, and even now the same remarks hold good, as the best flavoured produce is that grown without heat. I am aware in many Mushroom houses it would be far better not to use the heating apparatus at all, provided the house can be kept at a temperature of 45° to 50°. Many of the failures to grow Mushrooms arise from dry heat, want of moisture, and what may be termed sudden fluctuations of temperature. Many houses are built near the boiler house. This is fatal, as the dry heat is the cause of failure, it being impossible to maintain the humidity necessary to secure the fleshy Mushrooms, and insect pests are difficult to keep down. For years, having such a house to deal with, I used a cool shed and got excellent produce. In severe weather I used to bank up the fresh manure close to the door, and a little lower temperature did no harm. Many may have underground places, and here they will have fine crops. Materials should now be regularly prepared. The manure should be of the best, though in cellars I have used a good portion of short litter with the

droppings if the latter are well saturated with ammonia. Another plan is to mix soil with the material if the beds are of a good thickness. I am sure many beds are left to get too cool before spawning. I always spawn if the temperature is under 100° and falling. Another important point at this time of year is to get new spawn and of good quality. Beds may also be made with a small portion of decaying leaves; in fact, I have seen excellent produce from leaves and manure. Avoid over-heating the materials previous to making up. Beds made every month from this date to the end of March will give a regular supply, and after that period I make the beds in the open. Much may be done with beds in full bearing by giving liquid manure in a tepid state and adding salt, allowing the surface of the beds to dry before covering over and watering only when dry. S. M.

FRUIT HOUSES.

PINES.—The stock of Queen Pines for early forcing should by this time have made a sufficient growth for them to be gradually and steadily rested prior to being started afresh about the beginning of the new year. If this be the case the temperatures may be lowered both by day and by night. Do this by degrees until a minimum of 60° is arrived at for nights, except when frosty, then 55° may be touched without any harm happening. It has been a popular delusion that Pines must have a higher temperature than this, but it is not so when in this state. Many have practised it, and the result has been either adventitious fruiting or elongated foliage. A day temperature of 70° to 75° will be sufficient. The atmospheric moisture, too, should be diminished as well as water being withheld at the roots, but not to an excess should the occasion arise of having to maintain an undue amount of heat in the pipes. Watch the bottom-heat glass also, and do not let it indicate more than from 70° to 75° if possible. Syringe lightly between the plants upon the surface during fine weather. This will be ample for the present. Guard against drip and watch sharply for all insect pests, as cockroaches and crickets, which later on will do harm enough in eating the flowers. If they be starved now as regards vegetable matter, they will all the more readily take to poison. Plants now fruiting will still require the temperatures to be maintained fairly well, say 70° at banking-up time and from 80° to 85° by day, with at least 80° at the roots. As soon as colouring now commences no more water should be given, but in place of it adopt or continue the syringing just alluded to. The Queen Pine, of which late fruits are sometimes produced, is very apt to turn dark at the core if this treatment be not rigidly carried out. The Cayennes and other winter kinds are not nearly so much liable to this, hence a slight difference may be made in their case. Cut the fruits now when there is still a tinge of green upon the upper pips; they will then keep all the longer, and in the case of Queens in particular be safer to use also for the reason already given. If too many are ripening at one time the plants may be lifted out of the bottom heat for a few days and then be afterwards removed to a cooler temperature, being kept absolutely dry at the roots. Plants now showing fruit, in flower, or in their earliest stage of swelling must have the temperatures more fully maintained than in the case of those ripening. The utmost should be made of the present month for this purpose. Close early after having had a crack of air on to change the atmosphere in some measure and keep a brisk heat in the pipes at the same time. Be careful, even in the case of this stock, as regards watering, but give compensation by a humid atmosphere instead. At this season some plants are disposed to use any excess of vigour they may possess in developing crowns of large size. This may be checked by thrusting a hot piece of wire into the centre of each crown, which is better than allowing the leaves to grow more fully and then resort to pulling them out. This stock of Pines

is an important one for the Christmas season, hence it will pay to give every attention to it. Young plants of Queens and Cayennes which have not had time enough to make all the growth desirable may be still kept fairly warm, about as advised for plants now ripening. Let them, however, have all the light possible, and contrive also to keep them well up to the glass by re-arrangement if need be, for wherever the Black Jamaica or Lord Carrington is grown they will invariably be back row plants by reason of their longer leaf-growth. Do not now attempt any more potting, but if occasion arise substitute a manure instead. For this purpose Standen's is one of the best of all manures, being also highly concentrated, hence but little is required at the time. Those plants which are of sufficient size for the winter season may, on the other hand, be gradually rested by lowering the temperatures about 5°, but do not keep these too very dry at the roots, otherwise in the spring such as Queens will show fruit too soon. In every instance do not allow the foliage of Pines to touch the glass, otherwise a channel is at once afforded for the condensed moisture to run down into the hearts of the plants. The present is an excellent time for painting, cleaning, &c., in Pine stoves or pits, as room should now be available in Melon and Cucumber houses for storing the plants. Do not on any account let Pines get among the stove plants, where possibly the white scale may be lurking ready to pounce upon them. There is no enemy so much to be dreaded by growers of Pines as this pest. Mealy bug is bad enough, we all know, but upon Pines the white scale is infinitely worse. Look also to the heating arrangements, more particularly to the bottom-heat pipes, where a slight leakage may exist without notice, to break out into a serious one when more pressure is exercised in the circulation. A reserve of plunging material will be of service, but do not keep anything that is infested with vermin. Dry leaves now and soon to be secured will prove most useful. They will afford a normal or steady temperature, which may later on be increased by pressing them down and adding fresh ones. At such times pour boiling water into every nook and cranny, aiming at all insect extermination.

LATE MELONS.—The latest of these should now be ripening, and should any show signs of hesitation in this respect keep the temperature fully up to past standards, but guard against too much moisture at the roots, otherwise the flavour will be affected. Hero of Lockinge has been alluded to as a good late kind. If it be cut when well coloured, but before it is quite ripe, this variety will keep well for a fortnight or even three weeks. In spite of all the new kinds yet sent out with white flesh, there is no Melon, even those to which first-class certificates have this year been awarded, that can equal it in point of flavour, whilst it surpasses all Melons in appearance. Do not in any case permit the fruits now to hang too long, so when the first signs of cracking occur around the stalk, cut the fruits and place them in a warm, dry house, such as the late vinery, which is still kept up to about 55° or so at night. Should there be any surplus fruits, it is easy to use them up in the kitchen rather than let them spoil by keeping too long.

BANANAS.—The young stock of these should be well looked after, no check being allowed by a sudden drop of the temperature in houses where possibly other fruits or plants are being cultivated. There is no object or possible gain in prolonging their time of growth. If grown briskly from start to finish the results will be more satisfactory. Of course the season is coming on rapidly when growth will be much less; but, nevertheless, give the Banana all the warmth consistent with good results. The temperature of the average run of stove plants will suit very well, bearing in mind that stove plants even are improved by being kept fairly warm for at least another six weeks. Shield the foliage as far as possible from injury, allowing sufficient height for the leaves to rise and expand without being crippled against the glass. Pot or tub

young, vigorous plants into their fruiting sizes without any delay, and endeavour thereby to get them well rooted before winter is on us. Plant out also into pits with some fermenting material under the plants if no bottom-heat by pipes be available. Do not, even if it be not possible to do this work yet, let the plants become too much root-bound, but give them a temporary shift. Look after a sufficient stock of suckers to keep up the supply. It is not often a difficult matter to do this, being more frequently one of selection to get the stock at the right stages. These, if taken off now from fruiting plants, will make a good stock to start into brisk growth in the spring. At this season the Banana makes a capital addition to the dessert, and will do so onwards until the last of the "fingers" are ripe. Then do away with the old plants at once, when any dormant crowns under the surface can be taken off for future stock. Fruiting plants still in the green stage will be benefited by keeping the temperatures up as nearly as possible to the summer standards. Whilst the influence of the sun is still good this may be done with safety, but in using extra fire-heat be very careful in respect to insect pests.

HORTUS.

FRUIT AND VEGETABLE CROPS.

SUPPLEMENTARY.

Hurworth Grange, Darlington.—In the early spring everything appeared to favour an abundant fruit crop, but the cold east winds of May had a marked effect on Apples and Plums especially, and they are much under the average. Some kinds of Apples are fair, such as Ecklinville, Potts' Seedling, Cockpit and Bismarck. Pears are thin; Apricots are good and Peaches in case fine. Cherries dropped a good deal while stoning. Bush fruit is plentiful. Strawberries are a full crop, Royal Sovereign the best. The season was short, owing to the dry weather.

Vegetables are fairly satisfactory. Potatoes are good; Peas fine, but soon over. All other kinds are up to the average. The soil of the garden here is very heavy, and a dry season suits things pretty well.—J. SIMPSON.

Madresfield Court, Great Malvern.—In this district there is a good half crop of Apples. Many of the newly-established orchards on this estate show splendid samples of fruit, especially those trees planted in conjunction with Hops. The superior cultivation necessary for the successful growth of Hops gives a most marked object lesson worthy of every imitation by fruit farmers. The trees have a healthy look, are free from insect pests, leaves large and dark green in colour, the fruit smooth in appearance and of large size. Warner's King seems to be the leading Apple of the season. On turf, with the grass allowed to grow right up to the stem, it is painfully evident to see how the roots of the grass crop have used up the moisture and nourishment from the soil, thereby starving the fruit trees, which have a yellowish, sickly appearance and fruit correspondingly undersized and stunted. The protracted drought has told heavily upon such fruit farming. I never saw the subsoil so dry before, whilst on the heavy clay soils there is such a contraction as to cause huge cracks, with the consequent rupture of best roots and the inevitable letting in of drought. Pears are also in about the same proportion as Apples, but rather more partial. Cherries on suitable land are a paying crop, and the plantations are being increased. Apricots, Peaches, and Nectarines on walls are all full crops, but much difficulty was experienced in combating insect pests of the aphid tribe. Plums are the worst crop as to quantity; still quality has been excellent and the crop extremely partial, the ever-bearing Victoria, as usual, to the front. All the Gage family are very light, Pond's Seedling and Belle de Louvain being of enormous size. Bush fruits have been good average crops, Red Currants being of very large size and of grand appearance. Strawberries have

been enormous crops, Royal Sovereign being a great acquisition, ousting a good many unnecessary sorts. Sir J. Paxton, which has given enormous crops under ordinary generous field cultivation, is quite the sheet anchor of Strawberry growers for market. The new Japanese Wineberry (*Rubus phoenicolasius*) is an acquisition grown on wires similar to Raspberries, and gives a continuous supply of red, pleasantly acid fruits suitable for dessert or for ices. I am trying the Logan-berry, another of the American introductions, for the same purpose, but I have not had sufficient experience to say anything in its favour, although some of my friends who have succeeded with it are loud in its praise.—WILLIAM CRUMP.

Stoke Park, Slough.—Fruit crops in this district have varied much this season. In spring all our fruit trees promised well, being well set with fruit-buds, which opened fairly well, but owing to the cold in May the blossoms dropped very much; a great amount of the fruit that set dropped off when quite small. Fruit trees of every sort suffered very much from blight and insect pests. Peaches flowered grandly, but owing to the continued east winds during May, the trees were almost covered with insect pests. The nights being cold and frosty soon crippled the trees, consequently most of the blossom dropped prematurely without setting; what fruit set, swelled away and was grand when ripe, the size, colour, and flavour being quite exceptional. Owing to the excessive heat and want of rain Apples are smaller than usual, excepting on some old trees of Blenheim, which were bearing heavy crops; these, having been well watered and dressed with an artificial manure, are now (September 28) quite a treat to look at, the fruit large and colouring well. All the old-established fruit trees have withstood the exceptional drought the best. Young trees heavily mulched have done fairly well also. Apples, taken all round, will be about half a crop. Pears are good on wall trees, very uneven on standards, with much smaller fruit than usual. Plums vary; some sorts had heavy crops, Kirke's Green Gage and Oullin's Golden Gage, a grand dessert Plum, being the best. Cherries are almost eaten up with insects, what fruit there was being small and of inferior quality. Quinces flowered splendidly, but all dropped; trees have in some cases flowered a second time, the result a few small, worthless fruits. Of Mulberries there are very heavy crops, the fruits large, a hot, dry season evidently suiting them. Gooseberries are an enormous crop, a fortnight later in ripening than usual; Raspberries almost a complete failure, the fruits ripening off quickly and very small. Currants are a heavy crop, the fruit smaller than usual. Strawberries were splendid in every way, President being the best from plants put out in August, 1897. Filberts are plentiful, but smaller than usual.

Vegetables were splendid in the early part of the season. On ground deeply cultivated and liberally manured all crops have withstood the exceptional drought fairly well. Potatoes, earliest sorts, are fine crops and of good quality. The heaviest croppers are Windsor Castle and Sutton's Ninety-fold; the latter an enormous cropper. Later sorts have made a second growth, which greatly impairs the quality.—D. KEMP.

Batsford Park, Moreton-in-Marsh.—Last year fruit trees generally had very light crops, and the autumn being favourable for wood ripening, there was a splendid show of blossom this spring, Apple and Pear trees especially being pictures. There was practically no injury caused here by frost, and so far the prospect of a good fruit season was one which has seldom been surpassed. Unfortunately, in most cases it has not been fulfilled, as a dull, cold May, with prevailing north and easterly winds, seemed to give a great check and quantities of tiny fruits dropped. On the whole, the supplies here have been better than last year, though Apples and Pears are still under an average, and in many of the orchards fruits are very scarce. A few sorts grown as

garden pyramids seldom fail, and again keep up their reputation, the best Apples being Warner's King, Tower of Glamis, Magnum Bonum, Worcester Pearmain, Irish Peach (small), Cox's Orange and King of the Pippins (small), and Ribston Pippin, a nice lot on two trees that seldom fail to bear. Blenheim Orange, which is largely grown in this neighbourhood and depended upon for principal supplies, is variable and the crop generally light. Some pyramid Pears have heavy crops, notably Clapp's Favourite, Beurré d'Amanlis, Beurré Clairgeau, Vicar of Winkfield, and Gratioli of Jersey. Fruits on most varieties of better quality than these are scarce both in the open garden and on walls. Beurré Diel and Fondante d'Automne are fairly good as espaliers. Peaches and Nectarines flowered well and looked promising at that period, but later the trees were so badly attacked by blister and blight that many are almost worthless, and the fruits that remained are small and of poor quality. There has been a succession of unfavourable springs here for outdoor Peaches, which invariably weakens and disfigures the trees, because of the first growths failing to get away. Apricots did well and the trees have made healthy growth. The fruits were rather small but clean, and of fine colour, quality, and flavour. The varieties grown are Moor Park and Large Early. Plums are bearing well on walls with the exception of old Green Gage, which is nearly a failure, although the trees flowered well and had similar protection to Apricots. Bryanston, Braby's, Webster's, and Purple Gages on other walls have a very fair crop, and a similar remark applies to Kirke's, Coe's Golden Drop, Jefferson's, Woolston Black, and the Nectarine Plum. Two of the most useful kitchen Plums, Early Prolitic and Victoria, are heavily laden on walls. I have to net in winter in order to preserve the buds from destruction by birds. Standard trees in the open and unprotected are practically a failure. Cherries on walls were good, and the dessert kinds, excepting May Duke, kept clean. This variety and the Morelles were in the dry weather attacked by black fly. Strawberries were plentiful and wonderfully good, very few being injured by wet, as so little rain fell in July. The season was late, not many being ripe outside until nearly the end of June, and the supply kept up well through July. Royal Sovereign, as elsewhere, was very fine, the fruit being large and of excellent quality. Keens' Seedling, Sir Joseph Paxton, and President were as good or better than usual, while Vicomtesse Héricart de Thury, although small, is still grown outside, as it can generally be depended upon for a quantity of fruits which withstand rain much better than many varieties. Gunton Park and Lord Sulfield have been given a trial, and they promise to prove valuable for late supplies. Raspberries were as good as usual although rather small, probably from want of moisture. Currants of all kinds were mostly fine and clean, and Gooseberries plentiful where the bushes were netted last winter to preserve the buds. Walnuts are variable, some trees being heavily laden; other Nuts are plentiful.

Most vegetables have been good and plentiful, some being affected by the drought in July, while most of the winter crops have got away well since the rains came. The earliest Potatoes were uninjured by frost, and had clean, good crops free from disease. The haulm of the second earlies shows disease, and that of the early ones planted for succession. Magnum Bonum is chiefly grown for the main supply, and this variety has looked well. The first and second early Peas did the best of any and were very good. All the later ones in this garden have been attacked by mildew and thrips. Asparagus was plentiful, and Globe Artichokes have rarely done better, the plants sustaining but little injury through the mild winter. The land was in good condition for seed-sowing, but it was beaten rather hard afterwards by heavy rains. Beans of all kinds have been plentiful; so have Vegetable Marrows.

The rainfall in August has on two occasions been exceptionally heavy. On the morning of

the 7th the gauge contained 1.69 inches, and on the 16th the large quantity of 2.25 inches. Most of this latter fell on the night of the 15th in a heavy thunderstorm, which was of three hours or more duration.—J. GARRETT.

Elvetham Park, Hants.—Apples are abundant; Pears on the wall trees good crops, but those in the open are under average, the bloom having been injured by the late frost. Peaches, Apricots and Plums are average crops; Currants abundant; Gooseberries and Raspberries average crops; dessert Cherries average; Morellos abundant.

All vegetable crops have done well with the exception of Carrots. I have heard many complaints of the Carrot crops in this neighbourhood this year. We are now much in want of rain for the late Peas, the rainfall for June and July respectively being 1.57 inches and 0.55 inch; for August 1 to 23 only 0.93 inch.—G. MITCHELL.

THE MARKET GARDEN.

DAMSONS.

DAMSONS are among the most useful fruits we have. Being hardy and generally prolific, they require but little at the hands of cultivators, and it is on this account doubtless that many market growers both in Kent and elsewhere make a mistake. Everyone with a knowledge of the marketing of fruit has seen Damsons offered for sale and varying considerably in size, appearance, and quality. Here is a basket filled with large black, fleshy fruits that cannot fail to attract the attention of purchasers, and there another basket containing small, insignificant specimens having a half-fed look about them that is by no means prepossessing. The difference may be traced to good and poor varieties, or it may be owing to soil and situation, and again it may be, and often is, owing to treatment at the hands of the cultivators. Though Damsons are amongst the most accommodating of fruits, they appreciate good treatment, and if growers would always insist on pouring the liquid sewage from the farmyard, which often runs to waste, on to the roots of the Damson trees, a marked difference would be apparent in the quality of the fruit. Damsons are often treated as a chance crop of the farm, receiving but little attention in comparison with other fruits, and yet very often they play an important part on the profit side when the time comes for making out the balance sheet.

The keeping qualities of Damsons are much superior to those of most of the popular varieties of Plums, and therefore, by judicious management in gathering, storing and marketing in seasons of glut, fruit may be kept till after the rush is over and better prices can be realised. I know several growers, who are thoroughly conversant with their business, that use great judgment in the sale of their Damsons. If the market is crowded at the outset, they hold back a quantity of the fruit, which is kept in good condition after picking by spreading it out on shelves or on the floor of a cool, airy compartment, looking it over regularly and picking out any that may go bad. In a suitable place, Damsons spread out in this manner will keep longer than Plums, and when so treated, instead of realising prices that do not pay for picking, they give good returns after the glut is over. For home use I have known Damsons to be kept in good condition till after Christmas. Any crop that serves a double purpose cannot fail to be profitable one way or the other, and the Damson is one of these. Damsons are hardy, and form an excellent shelter in breaking the force of the wind from plantations of more tender fruits. In Kent

the Damson is largely grown for shelter, and fields of bush fruit may often be seen with rows of Damson trees along the sides most exposed to the wind. The growers as a rule pay careful attention to the bush and other fruits inside the plantations, pruning, digging, and manuring according to their requirements, but the Damsons demand no such close attention. When once planted on a suitable soil the trees want no pruning-knife to keep them shapely or assist their fruiting. All they need is sufficient room to grow at will, and if a little help in the way of sewage or liquid manure can be given, so much the better.

Though Damsons are hardy and prolific as a rule, they will not grow everywhere alike. It is very easy to see when Damsons are at home both from the appearance of the trees and the rapidity with which they increase, and it is a peculiarity about them that they are to be found growing in quantity in chosen localities, outside of which they are not a standard crop. This peculiarity of the Damson does not appear to be confined to any one county, and though in Kent Damsons are grown much more largely in some districts than others, the same thing is noticeable in other parts of the country. Staffordshire cannot be considered a fruit-producing county except as regards Damsons. The district I refer to is in close proximity to the river Dove, and for a radius of some miles Damsons may be said to be truly at home. The land is mainly pastoral, and dairy farming is the industry that pays the rent. But the Damsons also play their part, and the fruit here is purely a farm crop. To almost every homestead is a Damson orchard, and in some seasons the returns from this are very considerable. On the sloping hillsides where the soil is deep and the pasture superb for dairy purposes the Damsons are large, oval, and fleshy, while in other districts, where the sandstone lies close to the surface, the fruit is not nearly so large or of such good quality. Not only in orchards, but in meadows and along the hedgerows do Damsons grow freely. The trees are chiefly raised from suckers and transplanted in rather a rude manner to their permanent quarters. No pruning or after attention is given except in some of the orchards where manure, liquid or solid, is applied, though no doubt the continual grazing of cattle adds much to the welfare of the trees. The fruit is chiefly disposed of in the local markets, or is sold to dealers who hail from the great manufacturing towns in the midland counties. Prices vary much according to the crop. In seasons of plenty the prices are so low that they hardly pay for picking, though probably this state of affairs is owing to the want of better methods of distribution, because it must be borne in mind that fruit-growing in Staffordshire is not a main industry, as is the case in Kent. Dairying is the farmer's occupation, and his Damsons are an adjunct, to be disposed of in the readiest market. This year the Damson crop is light, and consequently prices are high. Only recently I was in a local market where farmers drove in with their butter, eggs, poultry, and hampers of Damsons. They were all displayed in old-fashioned style along the edges of the pavement, and in a mysterious way peculiar to the market through long custom the price seemed to set itself. The market was by no means glutted, and the price generally asked was considerably over a pound a bushel. Dealers bought up the fruit and despatched it elsewhere for various purposes, as Damsons are not only used for cooking and preserving, but also in the manufacture of colours. Staffordshire Damsons are not locally

known by any particular name, though the difference in shape and character proves that there are several varieties. In other counties the same peculiarity of the Damson in its preference for locality is noticeable. Kent also has its Damson districts, though the methods of cultivation and distribution differ from the illustration I have given.

The ease with which Damsons may be propagated has not altogether proved a blessing, as it has resulted in the extensive growing of some small insignificant sorts that are not honoured with a name. They may grow well, but the presence of the fruit in the market has the effect of keeping down the price for the best samples. In some districts there are plantations consisting of Damsons as standards with bush fruits underneath, and such sorts as Prune, King of Damsons and Bradley's King are grown. Again, the continual planting of suckers to raise fresh trees often results in barrenness, and I have known Damsons so raised to grow for years without fruiting, there being no other apparent cause for the failure except this.

In Kent Damsons come in among the last of the stone fruits, and most of them are disposed of through salesmen in the London markets. The crop is an important one, and last year many growers had good reason to thank their Damsons for the substantial addition they made to the returns. This season crops vary considerably, as in some districts trees are well laden, while in others fruit is scarce. Late frosts and blight are the bane of Damson growers, and this season the latter has been the chief enemy. Damsons grown in valleys and by the side of water often suffer through frost when in bloom, whereas those growing on higher ground escape. This season has been a most prolific one for all kinds of enemies and pests, and Damsons, alike with other fruits, have suffered. During the early part of the summer the trees were smothered with aphides, fruits in an early stage withered and fell, and trees presented a miserable appearance. This state of affairs was not so bad everywhere, and where the trees escaped or were not badly affected there is a fair quantity of fruit.

G. H. H.

CUT FLOWERS IN VASES.

NOT only to flowers should attention be directed, but also to the many and various kinds of foliage and grasses that may be used in arranging the same. Many of our hardy flowers which at present are more often found in cottage gardens might find a welcome where previously the selection had been confined to the products of the stove and greenhouse. In small establishments it is no easy matter to keep up the necessary supply from plants grown under glass, and a notice from time to time of the best, or at least the most suitable, subjects would be welcome. Then the range of hardy foliage and grasses is so wide, that from spring until the late autumn a wealth of material is available.

How often does one meet with most incongruous arrangements, and these frequently placed in most prominent positions. Violent contrasts, too, are often met with. The complicated arrangements in the epergnes staged at our leading exhibitions can only be considered beautiful when they are lightly and artistically adjusted with a proper blending of the colours and also with appropriate foliage added. Unfortunately, this is not often met with, and the best that can be said of many of them is that they are a very

mixed lot. The epergne seems to be falling into disuse, and vases, hand-baskets, &c., are more often used for table decoration. This seems to have many advantages, as greater novelty may be had from time to time. A fault with many is crowding the different subjects. Some of the most charming vases of flowers have been arranged in the simplest possible manner, and I can call to mind a large handful of Tea Roses, cut with long stems and with a profusion of richly tanned foliage adhering, simply dropped into a vase of suitable dimensions. The flowers of the Tufted Pansy have been treated similarly and placed into a shallow bowl of water with the happiest results. The huge blossoms of the Oriental Poppy, cut with long stems, give a most imposing and noble effect. Eight to twelve blossoms are ample for arranging in the largest vase, and then each flower has its own tale to tell. For the smaller vases during the summer what prettier subject than the Sweet Peas could be chosen? If these be cut with long stalks and a few pieces of the haulm and also a few buds for associating with the flowers, additional foliage is absolutely unnecessary. In the early summer the handsome blossoms of the herbaceous Peonies are often in demand for large vases, and the blossoms of the Tree Peonies are also equally useful. The great variety and wealth of colour and form of the Narcissi stamp them as indispensable for use in the spring. The season of these blossoms is now so long and continuous, that they are invaluable for all forms of decoration. It is important that their own foliage be freely used.

The accompanying illustration shows a very beautiful vase arranged with *Gladiolus The Bride*, with hardy Ferns and grasses in association, proving that a simple and unorthodox arrangement creates a far happier effect than the more stereotyped method of filling a vase could ever do. Coming to the present season, one can fully appreciate the use of some of the best of the *Helianthus*. H. Miss Mellish,

with its long, stout footstalks, is a handsome subject to use, and cut with buds and blossoms an artistic finish is easily obtained. The smaller and profuse blossoming sorts are seen to greater advantage in the smaller vases. Some of the Michaelmas Daisies are also useful for cutting. Of all flowers used I should think these are the simplest to arrange. Three or four sprays of the branching sorts placed in a large vase are a picture in themselves. No

stems, and thus rendered useful for more imposing decorations. Brightly coloured pieces of *Ampelopsis* are invaluable for adding to the richness of the colouring of the yellow, bronze, and crimson sorts. In November the large exhibition blooms may be turned to account. Six blooms with sprays of the scarlet Oak and similarly highly-coloured foliage will make a display of the handsomest kind, and as the flowers in a cut state last so long when the

Gladiolus The Bride, Equisetum foliage, Ferns and grasses in a vase. From a photograph by Mrs. Wakeman-Newport, Sandbourne, Bewdley.

foliage beyond their own is needed. With the *Chrysanthemum* season fast approaching, one's thoughts naturally tend in that direction. As the blossoms may be had during five or six months in the year, the *Chrysanthemum* deserves more attention than most other subjects. The hardy border sorts are invaluable for cutting, and now embrace many rich shades of colour. When these hardy sorts, many of them handsome Japanese flowers, are grown without disbudbing, they may be cut in sprays with long

water is renewed from time to time, the house may present a bright appearance for a considerable period. The leading *Chrysanthemum* societies are beginning to realise that a much better effect may be had with large blooms arranged in vases.—D. B. CRANE.

Mrs. L. Wakeman-Newport, who kindly forwarded the photo, in referring to the arrangement of the flowers, says:—

Nothing is more useful for decoration than *Gladiolus The Bride*. A few sprays in a tall

glass vase, accompanied by suitable grasses or the foliage of *Iris sibirica*, give you at once a simple and effective arrangement. This *Gladiolus* is as easily grown as a *Crocus*. Plant the bulbs in November in light soil, and put on the top of the ground a little straw or a few ashes to keep frost out. They then require no more attention till June, when they will be a waving mass of lovely white sprays. The accompanying illustration shows The Bride arranged with Male Fern, *Hordoum jubatum*, and leaves of the *Epimedium*. The lovely pink-tinged grass and young pink *Epimedium* leaves contrast prettily with the delicate white blossoms of the *Gladiolus*.

CHRYSANTHEMUMS.

NOTES ON CHRYSANTHEMUMS.

In my notes of a week or two back I stated that in my own as well as in other cases the plants appeared especially free from pests and so on, and that individual varieties had escaped usual troubles. Since then, however, something has made havoc among the buds of the variety *Mme. Carnot* and its sport *G. J. Warren*. They (the buds) seemed to be swelling freely, but all at once stopped. On examination many were found black and decayed in the centre. I caught several little green maggots buried in the buds, and fancy it is these which do the mischief. Other collections since visited assure me of a trouble more than local. In one instance, out of a score of plants the cultivator will not get half a dozen perfect blooms. Other sorts, too, are affected—for instance, *Lady Byron*, *Simplicity*, and *Western King*. It is strange how certain kinds are picked out for such destruction. Thrips damage the swelling buds to some extent, but I do not think the wholesale losses of this year are caused by so tiny a pest. Later formed buds of the varieties named do not appear touched, due no doubt to the return of less sultry weather.

Seldom have *Chrysanthemum* blooms grown for exhibition opened so early as this year. Fully-developed flowers of *E. Molyneux* and *Phœbus* are not usual in September. The buds generally are early this year and are advancing most rapidly. This season is unlike others that have passed in many ways. Ever since the plants were put entirely in the open we have not had any rain to speak of, and now (September 23) frost severe enough to blacken the leaves of *Dahlias* is recorded. I shall house mine without delay. Not that slight frosts hurt the buds before they burst, but it is hardly advisable to take any risks when so much time has been given to the *Chrysanthemum* for some months past. New sorts of much promise are unfolding their florets. General *Païque* thus early should be noted. It has flowers like the sort called *Golden Gate*, a distinctly handsome bloom in shape and colour. Its fault is that it is late. This detracts from its merits, at least from an exhibition point of view. President *Bevan* is another most promising new sort. Both are *M. Calvat's*, whose latest productions, now being grown in this country for the first season, seem likely to enhance his reputation. There is no mistaking them in their fine habit of growth and bold blooms. *Mme. G. Bruant*, a variety of last year, is very fine, of a clear colour, large in size, and of graceful form. *Edith Tabor*, the finest of all yellows when in fern, is opening well. So is *Mme. Gustave Henry*, a capital amateur's flower, being dwarf in growth and a handsome blossom, also of easy culture. *M. Heste* will be fully out in October. This should be noted. It is a very dwarf kind of easy culture, and produces well-shaped blooms of good quality, the colour being blush-white. *Werther* may be called an improved President *Borel*, a sort much esteemed a few years back. It is naturally early, and its colour bright purple-rose, decidedly showy. The growth, too, is desirable.

Among September-flowering kinds, the bronzy *Louis Lemaire* is an acquisition. The note in

THE GARDEN, page 249, commends it as exhibited recently. Being a sport from *M. G. Grunerwald*, it has the dwarf, free-flowering habit of that variety, and I think is the most satisfactory when the plants are not disbudged. *Mme. Marie Masse* is first-rate with me; quite the best pink early *Chrysanthemum*. The plants are not more than a foot high and are flowering profusely. The new peach-pink variety, *Mary Molyneux*, is doing well and opening the blooms freely. This English-raised flower ought to be seen in fine condition during the autumn. It is a rather tall grower, unfortunately. Late-struck cuttings of it have made capital specimens in 6-inch pots, and look like producing first class blooms, one to each plant.

Interest in new sorts will this year be keen owing to the introduction of many Australian seedlings besides the usual continental novelties. The former are evidently chosen on account of sturdy constitutions as well as for the beauty of the flowers. This is a proper thing to do, for a variety, however fine its blossoms, is not satisfactory if a bad deer. President *Nenin*, a kind thought very fine last year, is not doing well this, and will be discarded. I have noted it as a bad grower in other collections. The new variety, *Joseph Chamberlain*, will be valuable if it retains the character of last year, crimson *Chrysanthemums* being much wanted. The range of colour is none too varied when one considers the great number of novelties introduced each year. H. S.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

FRUIT SHOW, CRYSTAL PALACE, SEPTEMBER 29, 30, AND OCTOBER 1.

THIS exhibition, which is now looked upon as an annual one by fruit growers throughout the kingdom, was held on the above dates. It must be pronounced an unqualified success both in its extent and in the high average excellence of the exhibits. Having seen and taken note of each of these displays, we have no hesitation in saying that for all-round excellence it was the finest show yet held in the Crystal Palace under the auspices of the Royal Horticultural Society. Exhibitors of second-rate produce have now found out that it does not pay to come with their products, hence the high standard to which these shows have now attained. The number of exhibits was possibly less than last year, but it was in the number of dishes of individual fruits that a decided advance was to be noted. This arose from the greater competition in the collections, which made up fully for any falling-off in other respects. The marked superiority of the Kentish fruit was again manifest in both size and maturity, but not so much so as regards colour. On this occasion the finest coloured fruits of both Apples and Pears, notably the former, came from the western and south-western districts. There was a far higher degree of colouring manifest in the Apples from Dorset and Devon than in those from Kent, Sussex, or Surrey. This is no doubt easily explained from the fact that in the first-named counties the rainfall has been greater, consequently the moisture in the atmosphere has acted beneficially in this respect. Some districts have suffered to a serious extent during the long-continued drought, hence the resources of the trees have been severely taxed. The collections included in almost every instance fruit of the finest possible quality. The mixed collections of indoor and outdoor fruits stood high as regards quality. Two only, however, competed in the larger class of twelve dishes, which is at least two dishes too many at this

season of the year. It is only in the largest and best appointed gardens that twelve dishes of all-round excellence can be chosen, hence many are precluded from staging their fruit who would otherwise do so. Proof of this is forthcoming in the fact that on the present occasion the competition was much keener in the smaller class of eight dishes. The better arrangement would be to have three classes for collections of fruit for ten, eight and six dishes respectively. The small grower has no chance in the larger, whereas he might have in the smaller. Even the largest growers are put to straits in making up their numbers at times; this occurred at the recent show in one case at least, wherein both *Negro Largo* and *Brown Turkey Figs* were staged as one dish, which, according to the schedule, should be of one variety only; presumably this escaped detection by the judges in their scrutiny. The collections of both orchard-house and outdoor fruit were more extensive than last year, whilst the quality was excellent. Both Apples and Pears betokened thorough maturity, whilst from point of size there was nothing lacking even from the drier districts. Peaches, Nectarines, and Plums were shown in the greatest profusion, there being a distinct gain in these fruits from point of number and quality also; in fact, very rarely, if ever, have fruits of such high quality been staged. Grapes did not, on the whole, show any advance, whilst the number of bunches was less than usual. The finest white Grapes in the show were beyond any question the premier trio of *Muscat of Alexandria*. The best black Grape shown was *Mrs. Pince*, being absolutely perfect in finish and at the same time large both in bunch and berry. The nurserymen's classes were as usual the sources of great attraction, the well-known growers vying with each other to do their best. The new classes for different sections of the country were a distinct success and productive of much interest. The miscellaneous exhibits also stood out prominently for their general excellence. One practice rightly condemned by the judges was that of actually polishing the Apples; this cannot be too strongly condemned whilst still in the bud.

The arrangement of the show was all that one could wish; there was no symptom of overcrowding. A few blanks, on the other hand, did occur through failure in staging the respective exhibits as entered. This should be checked in some way, and that by radical measures if the exhibitor does not before the show day withdraw his or her entry.

It is to be earnestly hoped that means will be provided whereby the council of the Royal Horticultural Society will be enabled to continue these exhibitions of fruit at the Crystal Palace. This will depend upon the amount of support they receive from fruit growers and enthusiasts throughout the country. It is noticeable upon scanning down the lists of the past schedules that many who exhibit do not in return give any monetary support. This is, to say the least, not as it should be. Others appear to be eager enough to compete when money prizes are offered, yet do not put forth their exertions to aid the society at its fortnightly meetings at the Drill Hall.

DIVISION I.—FRUITS GROWN UNDER GLASS OR OTHERWISE.—GARDENERS.

For a collection of twelve dishes of ripe dessert fruit there were only two entries, both of which were good, but the adjudication of the prizes did not give the judges many anxious moments. Mr. McIndoe, gardener to Sir Joseph Pease, Hutton Hall, Guisboro, Yorks, was well to the front with

a uniformly good collection of well-ripened fruit. It consisted of Gros Maroc and Muscat of Alexandria Grapes, both well coloured; a fine Pine-apple, The Queen, as it ought to be shown, with fully developed pips; a Melon, The Champion, large and well netted; two dishes of Peaches, Admirable (?), yellow flesh, and Sea Eagle; one Plum in Bryanston Gage, a little short in colour but not in size; two of Pears in Souvenir du Congrès and Williams' Bon Chrétien, both excellent; one of Apples, Washington, extra fine and well coloured; and one of Figs, composed of Negro Largo and Brown Turkey mixed. Mr. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, was the other competitor, his collection being composed of one Queen Pine of medium quality; two dishes of Grapes, Black Hamburg, extra fine bunches, a strong dish, and Muscat fine in berry; two dishes of Apples, Gascoigne's Scarlet and Washington, the former the finer in appearance; two dishes Peaches, Gladstone, very good, and Exquisite, medium only, and wrongly named Sea Eagle; two lots of Pears, Doyenné Boussoch and D. du Comice, both excellent dishes; Pine-apple Nectarine, Countess Melon, and Coe's Golden Drop Plum. For eight dishes of fruit there was keen competition. The first prize was awarded to Mr. Jas. Dawes, gardener to Mr. M. Biddulph, Ledbury Park, Glos., who had of Grapes Gros Maroc, extra fine in bunch, berry, and colour, and Muscat, long tapering bunches, well finished; Princess of Wales Peach and Pine-apple Nectarine, both first-rate dishes; Worcester Pearmain Apple, highly coloured; Coe's Golden Drop Plum, poor in colour; a good Melon, and a clear fresh dish of Williams' Bon Chrétien Pear. Mr. Tidy, gardener to Mr. D'Arcy, Stanmore Hall, was a near second, his best selections being Muscat and Black Alicante of Grapes, both well finished; Sea Eagle and Walburton Admirable Peaches, the latter finely coloured; Humboldt Nectarine, characteristic fruits, highly coloured; Lady Sudeley Apple, large and clear; and Kirke's Plum, which had kept well. For a collection of six varieties of Grapes, two bunches of each, Mr. Goodacre was fortunate in being placed first (some experts present would only have placed him second). The best examples were Muscat, Madresfield Court and Gros Colman, all of which were quite up to the mark, whereas Gros Maroc was deficient in size, and Black Hamburg with Black Alicante lacked colour. Mr. F. Cole, gardener to Sir Charles Russell, came a very near second indeed, to say the least. Here the Black Hamburg was better in colour, as also was Alicante. Gros Guillaume and Appley Towers were the other black varieties, both being well finished; Muscat not so good as in the first prize lot, and Foster's Seedling, extra good, completed this exhibit. For Grapes in three varieties Mr. Dawes was again to the front with handsome bunches of Muscat, Gros Maroc, with medium berries, well coloured, and Black Alicante, rather lacking in colour. Mr. A. Belcher, gardener to Sir E. H. Carbutt, Nanhurst, Cranleigh, Surrey, was placed second, the Muscat there being inferior to those of his antagonist, but in black Grapes he was better in colour. This was quite evident in Alicante, whilst Gros Guillaume was compact in bunch and well finished. Black Hamburg was shown best by Mr. F. Cole, who scored in colour and berry, it being a fine exhibit. Mr. W. Mitchell, gardener to Mr. J. W. Fleming, Chilworth Manor, Romsey, who is rarely beaten for this variety, was so in this instance. The berries were larger, but the bunches were smaller, the colour alike good. For Madresfield Court the competition, on the other hand, was not so good. Mr. Mitchell was an easy first; his bunches were excellent in colour and berry. Mr. J. Jones, gardener to Mr. F. Need, York House, Malvern, was placed second, colour being deficient here. In the class for Gros Colman or Gros Maroc, the latter variety stood pre-eminent, all three prizes being awarded to it. The best bunches by far both in berries (very large) and finish were staged by Mr. Allan, gardener to Lord Suffield, Gunton

Park, Norwich; these were heavy clusters. Better colour, perhaps, was evident in the second prize bunches from Mr. Mitchell, but the berries were smaller. Black Alicante is invariably shown well at this exhibition. On this occasion Mr. W. Allan won the first prize with huge, heavy, well-finished bunches, showing the tendency towards a duplex character. Mr. W. Howe, gardener to Sir H. Tate, Park Hill, Streatham, was second with smaller bunches. The class for Lady Downe's was not so well filled. This fact need not call for any surprise, as many exhibitors might hesitate in cutting a Grape now which will keep easily and improve in flavour at Christmas. Mr. Taylor, gardener to Mr. C. Bayer, Tewkesbury Lodge, Forest Hill, was first with very handsome clusters, well finished, and Mr. W. H. Bacon, gardener to Sir Marcus Samuel, Mote Park, Maidstone, second with large bunches not well coloured. For any other black Grape, Alwick Seedling was the variety shown most, but it neither won the first nor the second prizes, although well-coloured clusters were staged. The first award went to Mr. Mitchell for Mrs. Pince's Muscat. He has shown this Grape well on previous occasions, but never so fine as these; they were superb bunches, coloured to perfection. The second prize was awarded to well-finished bunches of Appley Towers from Mr. Hudson. For Muscat of Alexandria the competition was not quite so good as usual, but it was keen as between the first and second prize winners. Mr. A. R. Allan, gardener to Lord Hillingdon, Hillingdon Court, Uxbridge, won a well-deserved first with huge bunches, clear in the berry and well finished. Mr. Duncan, Warnham Court, Horsham, was a very close second with fine, shapely bunches fine in the berry. With Mrs. Pearson (not shown extensively), Mr. Empson, gardener to Mrs. Wingfield, Amphyll House, was first with clear, clean clusters with large berries. In the second prize lot from Mr. Reynolds, gardener to Messrs. de Rothschild, Gunnersbury Park, the bunches were better coloured. With any other white Grape, Chasselas Napoleon from Mr. Reynolds was easily first, being staged in grand condition, possibly never better in colour, berry, and bunch. Mr. G. Lane was second with the same variety. For Figs the competition was not keen, being quite a contrast to last year. Mr. Mitchell was first with a good dish. For a collection of hardy fruit, not more than thirty-six dishes, grown partly or entirely under glass, Mr. R. Potter, gardener to Sir Mark W. Collett, St. Clare, Kemsing, Kent, was first, and Mr. McIndoe second, both of whom showed Grapes in good condition, but how Alwick Seedling and Gros Maroc Grapes can be termed "hardy," i.e., hardy as grown and shown, requires some explanation. Mr. Potter had in addition some grand examples of Pears and Apples as well as other fruits, but one dish of Pears only contained three fruits, whereas the schedule stipulates six. True, they were large enough, but, large or small, let the numbers be adhered to. Mr. Potter was also first for not more than fifty dishes of hardy fruits grown entirely in the open air, having similarly fine Pears and Apples to those in his first prize lot of orchard house fruit, many of the examples showing extra development for outside fruit, the whole forming a strong exhibit such as makes the Kentish growers hard to beat. Mr. John Powell, gardener to Colonel Brymer, Hsington House, Dorchester, was placed second, he pressing his antagonist hard, and being in turn pressed hard himself by other unsuccessful exhibitors.

DIVISION II.—NURSERYMEN ONLY.

In these classes we would like to see more competition, the large number of miscellaneous exhibitors showing that there is no lack of material. Messrs. Bunyard and Rivers were the leading exhibitors in the nurserymen's classes. In the class for a collection of fruit trees in pots bearing fruit, Messrs. Rivers and Son, Sawbridgeworth, secured the gold medal which was offered as first prize, the firm well sustaining their high character as fruit growers. The trees were remarkable

examples of high culture. A grand seedling yellow Peach laden with fruit formed the centre, there being smaller trees at the corners, the kinds being Albatross, Gladstone, Lord Palmerston, and seedlings. In this group were the best pot trees of Plums we have ever seen, the varieties being Pond's Seedling, Golden Drop, Rivers' Late Orange, a very fine late Plum, having grand colour, and seedlings. Very fine dwarf Apple trees formed the margin of the group, the most noticeable being Bismarck, Blenheim Orange, Emperor Alexander, the Melon Apple, Bijou, and several varieties of Figs. In the collection of hardy fruits grown partly or entirely under glass, Messrs. Bunyard and Co., Maidstone, secured the gold medal, this being the premier award. This collection was remarkable for the pot trees, these forming the background of the group and comprising the best kinds. The Pears in this collection were specially fine, Durondeau carrying immense fruits, Doyenné du Comice, Pitmaston Duchess, and Vicar of Winkfield being the other pot varieties. Peaches were good, Lady Palmerston being the variety mostly staged. Plums also were remarkably fine, Grand Duke being very large. The gathered fruits were equally fine, Conference, Marie Louise, Glou Morceau, Beurré Hardy, Beurré Diel, Marie Benoist, Pitmaston Duchess, and Emile d'Heyst Pears being the best. Sea Eagle and Nectarine Peaches were also good. The Apples, including Peasgood's Nonsuch, Gascoigne's Scarlet, Belle Dubois, Cox's Orange, Cornish Aromatic, Ribston Pippin, and other dessert, were excellent kinds. There were also nice fruits of Fig Bourjassotte Grise and other varieties. In the class for a collection of not less than seventy-five nor more than 100 distinct varieties of hardy fruits grown in the open air, two lots were staged. Here Messrs. Bunyard and Co. secured the premier award, as also the Dr. Hogg Memorial medal. We did not care for the centre pyramid of fruit surmounted by a tall Kentia, this looking far too artificial and stiff. The corners were more graceful, these being built up with highly-coloured Apples, such as Cellini, Lady Sudeley, Bismarck and Gascoigne's Scarlet. There were very fine fruits of Peasgood's and the new Allington Pippin. Duchess of Oldenburgh, Wealthy, Okera, a Swedish variety of great excellence, Worcester Pearmain and The Queen were well represented. Pears included Grosse Calebasse, Pitmaston, Souvenir du Congrès, Williams' Bon Chrétien, Mme. Treyve, Dr. Jules, a grand dish, and Beurré Mortillet. Plums in variety were also shown here. The second place was well filled by Mr. H. Berwick, Sidmouth, Devon, this table being tastefully decorated with Crinum, Asparagus and Ferns. The fruit in this collection was beautifully coloured, though not equal in size to the first-prize lot. The best Apples were Emperor Alexander, Gravenstein, Bismarck, Col. Vaughan, and Cox's Pomona. Pears were very good also, there being very fine fruits of Pitmaston, Grosse Calebasse and other stewing varieties. There was a better competition for from thirty to fifty distinct varieties of hardy fruits, there being very little difference between the first and second prize lots. The premier award went to Mr. Geo. Mount, the Rose Nurseries, Canterbury, whose collection was nicely set up, there being large mounds of Bismarck, Cox's Orange, Peasgood's Nonsuch, Worcester Pearmain and Gascoigne's Seedling, with excellent dishes of Lady Sudeley, Mère de Ménage, Cellini, Lord Derby, Lane's Prince Albert and The Queen Apples, with a few Pears. This was given the silver-gilt medal. The second prize went to Mr. T. Colwill, Sidmouth, the Pears in this collection being very good and the Apples grandly coloured, with splendid Peaches, Raspberries and other fruits. In the class for thirty-six distinct varieties of Pears only one lot was staged, this showing the scarcity of this fruit. In some of the dishes the fruits were smaller than usual. Mr. H. Berwick was the exhibitor, his finest lot being a remarkable dish of King Edward. Pitmaston was very fine, also Beurré Hardy, Durondeau, Beurré d'Amanlis,

Bourré Chairgeau, Knight's Monarch, Bourré Baltet père and Bourré Bachelier. For a collection of fifty dishes of Apples there was an excellent competition, and here Mr. Colwill was a good first, his fruits being of better colour than the others staged. Emperor Alexander, The Queen, Collini, and Red Bietigheimer were beautifully coloured. Tyler's Kernel, Bismarck, Bramley's Seedling, and Washington were very good among the cooking fruits, whilst Wealthy, American Mother, Duchess of Oldenburg, Worcester Pearmain, and Lady Sudeley were excellent dessert varieties. Mr. J. Basham was second, having fine fruits, but much marked with the netting which had covered them. Here were grand fruits of Tower of Glamis, Stirling Castle, and The Queen.

DIVISION III.—MARKET GROWERS.

This was a new class this year, and we would have liked to have seen a better competition. There was no question as to quality of the exhibits, but they lacked numbers and there was nothing now in the packing; indeed in a few instances the fruit was not well packed, as we noticed some had been bruised, and Grapes in many cases had lost a deal of their bloom. The first class was for 12 lb. of Hamburg Grapes in a fine wicker or baby basket. Only one lot was sent, and this being of poor quality the award was withheld. In the next class for any black Grape except Hamburg there were two competitors, only one prize being awarded, this going to Messrs. W. and C. Wells, Hattonburst, Hounslow, who showed well-coloured Gros Colman. The flat basket was fitted into a box, and this appeared to be a good system. For white Grapes, any variety, packed in a single layer, there was only one exhibit. This being Muscats of poor quality and badly rubbed was passed over. For Grapes packed in any other way there was one exhibit, and this was given first prize, Mr. J. Gore, Polegate, Sussex, receiving the award. These were packed in an ordinary hand-basket lined with tissue paper, the bunches being tied to the sides. The fruit had travelled without the least injury. For four varieties of cooking Apples in boxes or baskets, 42 lbs. in each, the first prize went to Mr. E. Basham. The baskets, nearly a foot deep, were oblong with lids, and contained two layers of fruit packed with wood shavings. The fruits had travelled grandly, and the cost of baskets was small. The second prize went to Mr. A. Wyatt, Hatton, Hounslow, who used ordinary market sieves lined with paper. The fruit was in good condition. In the class for dessert Apples, four varieties, about 20 lbs., packed in baskets or boxes, Mr. Wyatt was first with excellent fruit, having highly-coloured Cox's Orange, Worcester Pearmain, Duchess Favourite and King of Pippins. So far as we could observe the packing showed no new features, the ordinary market sieve being employed. Mr. G. Tebbutt, Isleworth, was second with smaller fruits, not so highly coloured. The corresponding class for cooking Apples brought forth more competition, there being five lots staged, the premier award going to Mr. Tebbutt for a very fine lot of Lady Henniker in a market sieve, Mr. A. Wyatt being second with Wellington in a similar package. The next class appeared to find more favour with exhibitors. There were six entries for 20 lbs. of dessert Apples, the leading exhibitor being Mr. McKenzie Brudley, Leyland, Meopham, Kent, who had fine Cox's Orange. We fail to see how a basket filled so high could be sent to market without damage if placed on another as is necessary. Mr. J. Jenner was second with the same variety. The next class should have been an interesting one. This was for 42 lbs. of Apples, any variety, showing an improved form of packing, but there was only one entry, and this was not considered worth the award. They were in a box in layers, without packing of any kind, merely a layer of wood wool on the top. The class for Pears in two packages of two varieties of 20 lbs. each, only brought three exhibitors, Mr. Wyatt being first with fine

fruits of Pitmaston Duchess and Williams' Bon Chrétien in ordinary market sieves. For twenty-four to forty-eight fruits, according to size, of any one choice dessert variety of Pears, packed in one package, there were four competitors, Mr. Wyatt being first with an even lot of Bourré Bose, there being two and a half dozen fruits placed close together on wood wool with pink paper divisions, Messrs. W. and E. Wells being second with good Souvenir du Congrès in a similar package. The next class was for cooking Plums in a basket or box of 28 lbs., one variety. There were only two lots, Mr. Darling, Ightham, Kent, being first for a small basket of Pond's Seedling. For a basket or box of 28 lbs. of Damsons, Mr. Darling was first with Farleigh Prolific. For Peaches, twenty-four fruits, packed in a box suitable for market, the packing and system to be especially considered by the judges, Mr. J. Gore, Polegate, was a good first, having grandly coloured fruits of Nectarine Peach and Sea Eagle. These were packed in tissue paper with wood wool. The judges recommended a special prize in addition for the excellence of packing. The second prize went to Mr. Miller, Ruxley Lodge, Essex. Surely there must be an error here, as this exhibitor is not a market grower only. In the class for 20 lbs. of nuts there were three entries, Mr. J. Jenner, Tonbridge, being first with large Kentish Cobs in a basket, and Mr. Darling second. The class for Tomatoes was an interesting one, and brought forth five exhibitors, the first going to Mr. Gore for nice fruits in layers in an ordinary handled market basket, the Froome Fruit and Flower Company being a close second with medium-sized fruits in a similar package.

DIVISION IV.—FRUIT GROWN IN OPEN AIR.

These classes did not bring forth the competition seen in past years. This was doubtless owing to the drought and heat in many cases. For twenty-four dishes of Apples, sixteen cooking and eight dessert, Mr. G. Woodward, Barham Court Gardens, Maidstone, secured the first prize, he being the only exhibitor. He had a very fine lot of fruit, which, however, lacked the size and colour of recent years. The cooking kinds most prominent were Peasgood's Nonsuch, Mère de Ménage, Bismarck, Emperor Alexander, Gascoigne's Scarlet, Stone's, Lord Derby, Alfriston, Eeklinville, Tower of Glamis, and Waltham Abbey Seedling; the dessert, Wealthy, Ribston, Mother, Cox's, and Worcester Pearmain. For twelve dishes there were six entries, and here Mr. Miller, West Farleigh Gardens, Maidstone, was a good first, having splendid fruits of Yorkshire Beauty and Ribston, the second being very close indeed. For nine dishes three lots were staged, Mr. Daws being first with grand dishes of Tyler's Kernel and Beauty of Kent, with excellent dessert varieties, Mr. W. Slogrove, Gatton, Reigate, being second. For six dishes of cooking Apples there were five entries, Mr. Woodward taking the premier position, having similar varieties to those named above, Mr. G. Loch, Newcombe Gardens, Crediton, being second. The fruit in the second prize lot had been very much polished, and we were pleased to see a note from the judges on the prize card condemning this stupid practice. For three dishes eleven competed. This shows the advantage of having small classes. Mr. A. Maxim, Heckfield Gardens, Winchfield, was first, having three grand dishes of Warner's King, Lady Henniker and Emperor Alexander, Mr. Lee being second. For six varieties dessert Apples Mr. Woodward was a good first with beautiful fruits of Wealthy, Washington, Ribston, Cox's, Worcester Pearmain, and American Mother, all well coloured. There were four lots staged, a great falling off from previous years. For three dishes Mr. A. Pentney, Worton Hall Gardens, Isleworth, was first, having good fruits of Ribston, American Mother, and King of Pippins. Mr. J. Tallack, Livermere Park Gardens, Suffolk, was a close second with good fruit. There were thirteen lots in this class. For dessert Pears, twelve dishes, Mr. Woodward was again in the leading place, there being three exhibitors. The

fruits were not equal to those of past years. The best were Bourré Mortillot, Durondeau, Gansol's Bergamot, Triomphe de Vienne, Doyenné du Comice, and Duchesse d'Angoulême. Mr. W. Allan, Gunton Park, Norwich, took the second place with grand Doyenné Boussoeh and others. For nine dishes, Mr. Pragnell was first out of four lots, having grand Bourré Diel, Marguerite Marillat, and Bourré Superfin, Mr. J. Powell, Hsington House Gardens, Dorset, being an excellent second, having one of the best dishes of Souvenir du Congrès in the show. For six dishes, Mr. Sage, Bayham Abbey Gardens, was first out of ten competitors, having very fine fruits of Doyenné du Comice, Gen. Todtleben, and Pitmaston Duchess, Mr. W. A. Cook, Compton Basset, Wilts, being a good second, he having fine Marie Louise. For three dishes, nine lots were staged, Mr. R. Edwards Offord, Sevenoaks, being first, and Mr. Fennell, Fairlawn, Tonbridge, second, both having fine fruit. For cooking Pears, Mr. Woodward was first in a small competition, Mr. Brown, Mote Park, Maidstone, being second. For a single dish of cooking Pears there were fourteen entries, Mr. Potter being first and Mr. Powell second. The class for Peaches was well contested, Mr. Woodward being a good first for three dishes. Thirty-six dishes in all were shown, these being good. The varieties taking the premier award were Sea Eagle, Princess of Wales, and Nectarine Peach, Mr. A. Maxim being second with the same varieties. For a single dish there was a much stronger competition, eighteen competing, Mr. G. Wythes, Syon House, Brentford, being a good first with grandly coloured fruit of large size, the variety being Sea Eagle. Mr. T. H. Wren, Bakenham Gardens, Staines, was second with the same variety. Nectarines brought few competitors, only three staging in the three-dish class. Mr. Woodward was first with Rivers' Orange, Pine-apple, and Humboldt—all of good size and finish, Mr. Earl, Somerhill, Tonbridge, being second. For one dish there were more entries, but not all of first-rate quality. Mr. Redden, Wickham, was first with Victoria. Here there was some mistake, as the best had evidently been overlooked. For four dishes of Plums a great number staged, Mr. J. Vert, Audley End Gardens, being a good first with excellent Golden Drop, Jefferson's, Transparent Gage, and Coe's Violet Gage; second, Mr. King, Gatton Park, Reigate. For one dish, twenty competed, Mr. Vert again leading with grand Golden Drop, Mr. Pope, Highclere, being second with Jefferson's. For Gage Plums, one dish, sixteen entered, Mr. King being first with grand Golden Transparent, and Mr. Powell second with Reine Claude de Bayay. Fourteen staged for four dishes of cooking Plums, Mr. Pope being first with Monarch, Grand Duke, Pond's Seedling, and Victoria, Mr. Vert being second, having fine Magnum Bonum. For one dish, Mr. Camm, Battle Abbey Gardens, had very fine Magnum Bonum, being first out of twenty-three competitors; Mr. A. Andrews, Campsea Ash, Wickham, being second. For Damsons or Prunes, Mr. Fennell was first with the Prolific, and Mr. Empson, Amphill House Gardens, Bedford, second, with the Chester variety.

DIVISION V.—SPECIAL DISTRICT COUNTY PRIZES.

In the classes open to growers in Kent there was not much competition, there being only three exhibits in the class for six dishes of Apples and one in the Pear class. Mr. W. Stower won easily in the former with fine dishes of Peasgood's Nonsuch, Lane's Prince Albert, Emperor Alexander, Bramley's, Worcester Pearmain, and Cox's Orange. The Marquis of Camden (gardener, Mr. G. H. Sage) was second. Mr. Sage also took the prize for Pears with a collection that would have stood well in good competition. The classes open to Surrey, Sussex, Hants, Dorset, Somerset, Devon, and Cornwall brought out a fine lot of splendidly coloured fruit, ten competing in the Apple class and nine in that for Pears. The Duchess of Cleveland, Battle Abbey (gardener, Mr. W. Camm), was placed first, though the

judges must have had a great difficulty in deciding between this collection and the magnificent lot put up by Mr. G. Lock, gardener to Mr. B. H. Hill, of Crediton. The fruit from the latter grower was very fine in every way, and comprised grandly-finished and finely-coloured fruit, but polished too highly. His Peasgood's Nonsuch was shown as only west of England growers seem able to show this fine Apple, Emperor Alexander and Ribston being also unmistakably good. For Pears, Mrs. Crawford, Reigate (gardener, Mr. Slogrove), won easily with a very even and good collection, Souvenir du Congrès, Fondante du Cour, and Louise Bonne being the best dishes. Mr. H. Padwick was second, showing a fine dish of Doyenné du Comice and good Marie Louise. The growers from Wilts, Gloucester, Oxford, Bucks, Berks, Beds, Herts, and Middlesex brought a lot of fruit of good quality, but deficient in colour, the number of entries being the same as in the last batch of counties. In the Apples, Mr. Turton, gardener to Mrs. Nicol, of Maiden Erleigh, scored. He had very even dishes, his best cooking kind being Warner's King, the Cox's Orange and Ribston Pippin being very fair fruit. For second place, Mrs. Wingfield, Ampthill House (gardener, Mr. Empson), had finely coloured Lady Sudeley and Worcester Pearmain, a nice dish of Stone's being also included. The Pears in this section were very fine, the first prize going to Major Heneage, Compton Basset (gardener, Mr. W. A. Cook). In this lot there was an exceptionally fine dish of Williams' Bon Chrétien and one marked Doyenné du Comice; Marie Louise and Louise Bonne of Jersey were also very fine, but a little deficient in colour. For second place, Mr. F. M. Lonergan (gardener, Mr. Chamberlain) had a nice, clean and even lot, the useful Clapp's Favourite being well shown. Five growers competed in the Apple class open to Norfolk, Suffolk, Essex, Cambs, Hunts, and Rutland, and two in that for Pears. In the former the competition was very keen, and Mr. H. H. Hurnard was fortunate in obtaining the first place. Peasgood's Nonsuch and Cox's Orange were his best dishes, the latter a very even lot. Mr. E. Dresden, Livermere Park (gardener, Mr. J. C. Tallack), was a very close second, Ribston and Warner's King being the best of a neat and even collection. In Pears the Hon. J. Lowther (gardener, Mr. Andrews) won somewhat easily, showing fine Souvenir du Congrès and clean samples of Doyenné du Comice. This was a fair collection, but the second prize lot was very rough and uneven. These were staged by Mr. J. W. Mellis, Sewardstone. In the classes open to Lincoln, Northampton, Warwick, Leicester, Notts, Derby, Staffs, Shropshire, and Cheshire the Apples were fine, but not highly coloured, and it is noteworthy that a new exhibitor, and from perhaps the coldest of the counties, should have won somewhat easily. This was Mr. John Lee, of Higher Bedington, Cheshire, and the collection was even and good. Mr. Divers, gardener to the Duke of Rutland, Belvoir Castle, Grantham, was second, his Cox's Orange Pippin being a nice even dish. There were two entries for Pears, and here Mr. Thos. Bennet, of Market Drayton, beat Mr. Divers. The fruit in both cases was even and clean, but not large. The entries from Worcester, Hereford, and neighbouring counties were very disappointing in point of numbers, but the quality was distinctly good. Only two collections of Apples were shown, Mr. Richard M. Whiting, Credenhill, Hereford, winning rather easily. His Peasgood's Nonsuch were beautiful fruit, and Worcester Pearmain was exceedingly well coloured. Queen Caroline and Cox's Orange Pippin were the best dishes in the second prize collection, and this also was won by a Herefordshire grower, Mr. R. E. Bateman. There were no Pears in this section. From the other Welsh counties the fruit was not of special merit, the Dowager Lady Wynn and Mr. L. Pugh taking first and second places respectively both for Apples and Pears. Two growers only competed from the six northern counties, and here again the fruit was poor. The

Earl of Hereford (gardener, Mr. J. Jeffrey) was first for Apples; Mr. R. J. Hird second. No Pears were shown. Only one grower turned up from Scotland. Mr. Day, gardener to the Earl of Galloway, Galloway House, Carlisle, was awarded first prize both for Apples and Pears with a very creditable collection. His best Apples were Worcester Pearmain and James Grieve, his Mme. Treyve and Gratioli of Jersey Pears being excellent. There were no Irish exhibits.

DIVISION VI.—SINGLE DISHES, APPLES—DESSERT.

In the single dish classes, competition was keen. There was a notable falling off in one or two generally popular classes, such as those for Blenheim Orange and King of the Pippins. On the other hand, some, such as Bramley's and Newton Wonder, made a much better show than usual. Pears were very good, perhaps a trifle smaller than usual. Most of the highest coloured Apples came from the west of England, Kent being but little better in that respect than the more northern counties on the east side of the country where the drought has been so great. Of Adams' Pearmain, eight dishes were shown, the first prize going to Mr. G. Lock, gardener to Mr. B. H. Hill, Newcombe, Crediton, for a beautifully coloured half-dozen, rather below in size one or two of the other dishes shown, but well finished; the second prize going to Mr. Camm, gardener to her Grace the Duchess of Cleveland, Battle Abbey, colour again influencing the decision. A rather poor lot, four dishes, of Allen's Everlasting was shown, the first prize going to Mr. H. Henley, gardener to Mr. E. J. Johnstone, Rougham Hall, Bury St. Edmunds, for a nice dish; Mr. J. Powell, gardener to Colonel Brymer, M.P., Ilington House, Dorchester, taking the second place. The new Allington Pippin brought out seven lots, the placed dishes being very fine. First prize went to Mr. Geo. Woodward, gardener to Mr. Roger Leigh, Barham Court, Maidstone, for a beautifully finished lot; second, Mr. J. Powell, Ilington House, for larger, but more uneven fruits. A good dish also came from Mr. Hudson, gardener to Mr. Leopold de Rothschild, Gunnersbury House, Acton. Nine good dishes of Baumann's Red Winter Reinette were shown, Mr. Woodward securing the first prize with grandly coloured and very even fruits, Mr. W. Slogrove, gardener to Mrs. Crawford, Gatton Cottage, Reigate, securing second place. Blenheim Orange was not so well represented as usual. Only sixteen dishes were staged, first prize going to Mr. T. H. Slade, gardener to the Right Hon. Lord Poltimore, Poltimore Park, Exeter, for a good, even and well-coloured lot, Mr. Richard M. Whiting, Credenhill, Hereford, being second with rather smaller fruits, which were, however, nicely coloured and clean. Want of colour was a weak point in this as in many other classes. Of Brownlee's Russet there were six dishes, the first two being remarkably good and hard to choose between, Mr. Geo. Chambers, Mereworth, Maidstone, being first, and Mr. Woodward second. Of the seven dishes of Claygate Pearmain, one or two were very weak. Mr. Richard M. Whiting's first prize dish was, however, grand, and these were the only well-coloured fruits in the class. Mr. Woodward's second prize lot was also fine, but somewhat green, a defect which lost him first place. In the next class, Cackle Pippin, where his fruits were far beyond any other in size, Mr. Samuel Kidley, gardener to Mr. W. A. Sandford, Wynehead Court, Wellington, Somerset, was placed first with a beautifully even and well-coloured lot, the second going to Mr. H. Henley for smaller and russet fruits. Five dishes were staged, and all were very clean and good. For Court Pendu Plat, Mr. J. C. Tallack, gardener to Mr. E. Dresden, Livermere Park, Bury St. Edmunds, was placed first for an excellent dish of large and well-coloured fruits, Mr. J. Vert, gardener to the Right Hon. Lord Braybrooke, Audley End, Saffron Walden, coming second with fine fruits also, but poorer in colour. Eight good dishes were staged. Cox's Orange Pippin, always a strong class, brought

but no less than twenty-five dishes, and they were mostly grand fruits. Mr. W. King, gardener to Mr. Jeremiah Colman, Gatton Park, Reigate, showed a perfect dish for first place, closely followed by Mr. Woodward. Other grand dishes came from the neighbourhood of Maidstone, Hereford, and Devonshire, Surrey being also well represented in this class. Six dishes of Duke of Devonshire were shown, first prize going to Mr. G. H. Sage, gardener to the Marquis of Camden, Bayham Abbey, Lamberhurst, Mr. Prinsep, gardener to the Viscountess Portman, Buxted Park, Uckfield, being second. Six dishes also represented the class for Egremont Russet, first prize going to Mr. C. Earl, gardener to Mr. O. E. d'Avigdor Goldsmid, Somerhill, Tonbridge, for an excellent dish. Mr. Richard M. Whiting, Credenhill, Hereford, was second with beautifully coloured but smaller fruits. Four of the six dishes were very good indeed. Nine dishes of Fearn's Pippin were staged, mostly well-coloured but not nearly so fine as last year. The first prize dish from Mr. W. Stowers, gardener to Mr. G. Dean, Whitehall, Sittingbourne, was exceedingly fine, Mr. G. Lock, of Newcombe, Crediton, being second with much smaller fruits. The six dishes of Gascogne's Scarlet varied much in size. Three were excellent, the first prize going to Mr. W. Stowers, the second to Mr. F. W. Thomas, Wannoch, Polegate, Sussex. Two dishes only of James Grieve were shown, Mr. Day, gardener to the Earl of Galloway, Galloway House, Carlisle, N.B., being first with a grand dish, and Mr. F. B. Parfitt, Farleigh House, Reading, second. King of the Pippins was less numerous and not nearly so good as usual, being very deficient in colour and undersized. Mr. Geo. Chambers, Mereworth, Maidstone, was first with a good dish for the season, and Mr. Prinsep second. Ten dishes only were shown. Four uneven dishes of King of Tomkins County were staged, Mr. Woodward coming first with fine fruits, and Mr. J. Powell second. Eight dishes of Mannington's Pearmain were staged. Mr. T. Turton, gardener to Mrs. G. Garden Nicol, Maiden Erleigh, Reading, was first with a nice and well coloured lot, Mr. C. Harris, gardener to Mr. O. A. Smith, Hammerwood Lodge, East Grinstead, being second. Margil brought out twelve dishes, and is rarely seen in such fine form, the colour very good and the size phenomenal for this generally small variety. Mr. Woodward was a good first, and Mr. T. H. Slade second, both having excellent dishes. Other grand dishes had to be passed over. Only one really weak dish was shown. Of American Mother there were but five lots, Mr. Woodward being first with fine highly coloured fruits, and Mr. H. Henley, of Rougham Hall, second, with good but less coloured examples. Ribston Pippin was not so generally good. Sixteen dishes were staged; a few rather poor. Mr. T. H. Slade was first with highly coloured but not large fruits, and Mr. Edward Chopping, Periwinkle Mill, Milton, Sittingbourne, second, with slightly larger but less coloured fruits. The six dishes of Scarlet Nonpareil were not very good, the season apparently not suiting the variety. Mr. Woodward had colour and was placed first, Mr. Hudson being second with an even but rather green set. This class contained two dishes wrongly named. Sturmer Pippin brought out six dishes, rather uneven, but Mr. W. G. Pragnell, gardener to Mr. J. K. B. W. Digby, M.P., Sherborne Castle, Dorset, showed a fine dish for first place, and Mr. R. Chamberlain, gardener to Mr. F. M. Lonergan, Cressingham Park, Reading, was second with good fruits also. Worcester Pearmain was shown in good form, fourteen highly coloured lots being put up, Mr. W. King, of Gatton Park, securing first with medium-sized but superbly coloured fruits, Mr. Woodward being second with larger fruits, less highly coloured. The any other variety class brought out twenty good dishes, mostly well selected and in good condition, the judges, however, apparently, judiciously abstained from testing the flavour of any, and Mr. Woodward was placed first for an exceedingly handsome dish of

ORCHIDS.

ONCIDIUM FORBESI.

THIS, one of the handsomest of cultivated *Oncidiums*, requires some care to keep it in health and flower it annually. In its best forms the beautiful yellow margin is like a laced edge, the ground colour of all the segments being a deep chestnut-brown, shining and glossy as if varnished. Many growers who succeed with this species for a few years imagine they have discovered the way of growing it. It may be they give more heat than usual, or by some special addition to the compost get a larger growth than usual for a time, but this success is only temporary, and very often, owing to experimenting in different ways, the plants are disturbed and made worse than before. The plant is difficult to keep in health over a long series of years, and it is usually impossible to improve on imported specimens. It is a native of the Organ Mountains, in Brazil, and though occasionally fine plants are met with in quite a cool house, I have had better results by treating it to a little more warmth. The growths seem to come away with greater freedom, and the roots take more water than when grown quite cool. But of far more importance even than this is the need of preventing over-flowering. More plants of the species have been killed by this than by any other detail of mismanagement, for not only are the flower-spikes very large in comparison with the bulbs, but the blooms remain in good condition a very long time, and thus distress them greatly. I would never allow weak plants to flower, and by weak plants I mean any that have pseudo-bulbs less than 2½ inches high and proportionately stout, while the plants that do flower should have the spikes removed after, say, a fortnight. The vigour of the plant will be kept up in this way as well as it is possible to keep it. Other matters needing attention are keeping the plants clean and in a sweet rooting medium,

and as near their proper routine of growth and rest as possible. The best compost is one that allows the moisture to pass readily through it, yet holds sufficient for the needs of the plants. The strongest plants need not have more than a depth of a couple of inches, while considerably less than this will usually suffice. Owing to the habit of the plant being less spreading than most of the crispum set, small pots are more suitable than the rafts and shallow baskets often successfully used for these. Everything should be done to promote healthy and abundant root action, as on this largely depends the health of the plant. As soon then as the least sign of souring appears on the surface compost, let this be removed and new material substituted, no matter what time of year it is. During the winter season, when evaporation from the compost is slow, it is surprising what a long time this species will go without water. On the other hand, when growth is active, and even afterwards while the plants are in flower, there is a considerable demand upon the roots, and this must be met by a free water supply. Overhead watering is not particularly relished by this plant, though a light spray very finely broken up is of assistance during hot weather. A good deal may be done for weak and badly-rooted plants in this way not only for the species under notice, but also others. It is no use watering the compost, as there are no roots therein to take up the moisture, but the spray referred to checks evaporation from the foliage and is refreshing all round. Scale and thrips are its worst insect enemies, and unless these are kept down, the former by sponging and the latter by vaporising, healthy growth is quite out of the question. It is rather a singular fact that the better forms are often the worst growers, the fine variety *O. F. grandiflorum* being weaker than the type, though producing larger flowers in fine branching panicles. H. R.

Distichous-leaved Epidendrums.—These are very useful where room can be found for them,

for some one or other of the species is almost always in flower. In most cases they are showy and bright in colour and make a welcome change from the usual dwarf species for grouping. There are one or two exceptions, but as a rule they are very easily grown. The roots like plenty of room, a rough, open compost and plenty of water while growing freely. A few of the smaller-stemmed kinds like smaller pots, but, as with many other Orchids, the size of the roots may often be taken as indicating the size of pot and class of material they may be expected to thrive in. The majority may be grown in what may be termed a cool intermediate house, a very moist atmosphere being greatly to their liking, and encouraging the production of plenty of air roots upon the species having this habit. As a rule a central stage in a fairly wide house is best for these plants, but smaller houses may be made suitable, the plants being grown under the roof. Grown in this way some care is required in shading, but otherwise the plants do well and almost always flower freely. This treatment is most suitable for the more slender growing kinds, as those with very stiff stems would not be easily kept from growing up to the glass.

Pilumna fragrans.—The pure white flowers with dense yellow eye of this species are always welcome, but it is rather erratic in its time of flowering. The perfume where a number of blooms is open is very delicate, and the plants look very beautiful backed by Maiden-hair and other Ferns. Like others in the genus, it may be grown with ease provided the roots are well looked after, but these being somewhat large are very susceptible to injury if the compost gets at all close or water-logged. Once the roots are gone it is difficult to induce the plants to produce others freely. With ordinary care in the preparation of the compost and in watering afterwards this need not happen, and as long as the roots are healthy no fear of the plants need be entertained. Water should be withheld to a great extent during the time growth is inactive, and it is not a particularly thirsty subject at any time. It delights in light syringings over the foliage, this treatment serving to keep insects in check, especially thrips, which often attack the foliage. It also keeps the leaves more plump and strengthens the entire plant. It must, of

course, be discontinued during wet weather and in winter.

Scuticaria Steeli.—The long terete foliage of this Orchid makes it an interesting plant, and the flowers are also very distinct and pretty. These occur on short peduncles, seldom more than two on each, and are pale yellow on the sepals and petals, spotted with brown, the lip bright orange. Under cultivation this Orchid requires abundant heat and atmospheric moisture and almost entire exposure to the sun. Not being a very vigorous rooting plant, no great amount of compost is necessary, and I have seen fine plants on almost bare blocks. This is, however, too poor, and if baskets of medium depth, well drained, and with an inch or so of peat and Moss are provided, the plants will do better. The tips of the leaves are very apt to be injured while growing if touched or bruised, and for this reason it should be hung out of the way as much as possible. During the time growth is active a plentiful supply of water is necessary, for the thin compost soon dries, but when at rest very little suffices for it. Treated well, it is not uncommon for the leaves to grow a yard and a half in length, and it is such plants as these that give the finest flowers. *S. Steeli* is a native of Demerara and other parts of South America, where it grows on trees near the river banks. It was introduced in 1836, and first flowered with Mr. Moss, of Liverpool, in 1837.

Cypripedium Spicerianum.—There are some nice forms of this useful and beautiful species now flowering at Syon House. There are few prettier Cypripediums in cultivation, the pure white dorsal sepal, with its median line of deep purple, being very striking and showing richly against the somewhat sombre hues of the other parts of the flower. Now that this beautiful plant is well established in collections cultivators grow it far better than was formerly the case, and it is not at all uncommon to see fine healthy batches of it where it used to be quite a failure. It will be a good thing for amateur cultivators when they wake up to the fact that for many years they have been starving their Cypripediums by keeping them for years in the same pot, allowing them to get potbound and seeing the growths dwindling yearly. It is surprising what grand results may be obtained with some of the older and commoner species by growing them well, by giving new compost just when they begin to tire of the old instead of waiting until the effect of sour and used-up compost is apparent. The more experience they get the greater will be the need of keeping them vigorous and healthy when they are so. A strong plant is improved by being given fresh material, while a weak, half-starved one cannot stand disturbance.

Epidendrum sceptrum.—This is one of the prettiest of the Epidendrum with inverted flowers, and rather a variable one as regards colour. Many forms are, or used to be, in cultivation with white, or nearly white, flowers, the spotting on the sepals and petals being light purple. Others are golden yellow, similarly spotted, and there are intermediate forms. In habit it is rather tall, the stems bearing several fine green leaves, from between which the flower-spikes issue. Its culture is practically the same as for other species in this section, the roots being fairly large and liking a rough, open compost and medium-sized pots. A cooler house suits it, and I have lately seen a fine plant with healthy green leaves and several flower-spikes in a house chiefly devoted to Odontoglossums. The atmosphere, of course, was kept very moist, and during the greater part of the year it was in company with the plants named above, lightly sprayed with the compressed air pump now coming to the front in Orchid growing. During the season of growth plenty of water is necessary, but the season is not always the same. While resting, just enough moisture to keep the pseudo bulbs plump must be given. *E. sceptrum* was formerly much more plentiful in collections indeed, it is now seldom seen. It is a native of Oceana and various

parts of New Grenada, and was discovered and introduced by M. Linden about 1843.

Dendrobium album.—In habit this species favours *D. chrysanthum* a good deal, but the flowers are quite different. A large number of plants of it have been sent to this country from time to time, but for some reason it has never become at all popular, and is, I think, even less so now than formerly. It is rather a pity, for the flowers are produced very freely in short racemes of two, seldom three each, from the apical nodes of the pendulous stems. These are creamy white, with a stain of yellow on the lip. A little care is needed to grow it well, as very often it begins to push young growth in early winter, at a time when growth on other plants is at a standstill. These young shoots must not be checked, or good results will not be obtained. The stems on well-grown specimens ought not to be less than 18 inches in length, and I have frequently seen them much longer. Grow them as well as possible, then, during winter, and if they are not checked before the days begin to lengthen, they will finish their growth rapidly and often flower upon the young shoots before the foliage has fallen. Occasionally a few flowers are produced the second year, a circumstance I have never noted with *D. chrysanthum*. The species is a native of Southern India, and was introduced by Messrs. Loddiges in 1842.—H.

SOPHRONITIS.

THERE are but three well-marked species in this genus—though one of these, *S. grandiflora*, is rather a variable one—that are at all well known. The name when applied to some of the varieties of the above-named species seems scarcely applicable, though to the type species, which was the only one known at the time the genus was named, it applies well enough. All are dwarf-growing plants, requiring little in the way of compost, but they must not on this account be neglected or grown under too bare conditions. For *S. cernua* and *S. grandiflora* I know of nothing better than the small pans used for suspending near the glass, these, while holding enough for the proper development of the species, rendering it almost impossible to overload the roots with compost. They should be about three parts filled with clean, small crocks as drainage, covering this with a little rough Sphagnum Moss and leaving the remaining third for compost, this consisting of the usual peat and Moss mixture, with abundance of small crocks added to keep it open. When repotting, the small pseudo-bulbs, which grow very closely together in both the above-mentioned species, should be cleared at the base of all mossy deposit, which even in the best description of peat is sure to be present. At the same time avoid disturbing the roots or breaking up the tufts more than is really necessary. The more the clumps are kept together—provided always they are healthy and have no old, decayed bulbs in the centre—the better, as they are more readily fixed in position and not so liable to become loose at the surface of the compost. The surface should be somewhat convex, as it is difficult to fix this class of Orchid if set up too high.

The somewhat rambling habit of *S. violacea* renders a rather different mode of treatment as to a rooting medium necessary. The tiny pseudo-bulbs appear at a considerable distance apart upon a slender creeping rhizome, so that if placed in pans it would soon grow out over the edges, and necessarily out of the reach of benefit from the compost. This, then, must be avoided either by making up large and very shallow pans or by allowing it to run up a block of wood or Tree Fern stem. The former plan has little to recommend it, as the pans would be

very heavy, and the small amount of compost necessary would render it difficult to fix the rhizomes in position. With wooden blocks, on the other hand, lightly dressed with Sphagnum Moss and a little peat, it is an easy matter to use copper wire and tacks and so fix the rhizomes on a small cushion of compost. Thinly-cut strips of cork may go under the wire to prevent the latter cutting into the rhizome. On a Tree Fern stem still less Moss is needed—indeed, the sooner the roots enter the stem itself the better, as this holds plenty of moisture for their needs without anything else. With regard to temperature and position for Sophronitis, there is no better than one close to the roof in a house kept at a slightly higher temperature than the cool house, as usually understood, where all the New Grenadan Odontoglossums and similar Orchids flourish. Where Odontoglossum grande does well in the body of the house, Sophronitis should thrive on the roof, provided other details of culture are well carried out. A very moist atmosphere and shade from bright sunshine are essential. The roots, too, on healthy, well-established plants must be kept moist all the year round. The more regular the temperature and atmosphere are kept and the freer from draughts or drought, the better these little plants thrive and the less trouble they will give as regards insects. Perhaps the worst of these that affects Sophronitis is a troublesome small scale. It is especially common on *S. violacea*, and requires great attention in the way of sponging to keep it off this species. As noted above,

SOPHRONITIS CERNUA is the type species and is a native of Rio de Janeiro, where it was discovered some time previous to 1826 by Mr. W. Harrison, a Liverpool merchant, at that time trading with South Brazil. The pseudo-bulbs are so tightly clustered as to appear a cushion-like mass, and from the base of the short leathery leaves the flower-spike proceeds. This bears only a few blossoms, the colour being a bright red, with yellow centre.

S. GRANDIFLORA and its varieties are the best known of all. They produce magnificent flowers, larger, perhaps, for the size of the plant than those of any other Orchid known. In colour they vary from bright scarlet to rosy purple, the usual size being about 2 inches across. Few things are finer in dull October and November than the bright and showy blossoms of this plant. In company with

S. VIOLACEA it was introduced by the successful collector, Gardner, who sent them home about 1837 to Messrs. Loddiges, of Hackney. The flowers of *S. violacea* occur on two or three-flowered peduncles usually in late winter and early spring. The colour is a pretty magenta or violet, with a lighter area around the column and base of the lip. H. R.

Lælia anceps alba.—It is rarely one can record the free flowering of the white forms of *L. anceps*. There is at the present time a huge specimen of *L. a. Sanderiana* throwing up upwards of two dozen spikes of flower, and a plant of *L. a. Schroderi* of smaller dimensions, carrying twelve flower-spikes, in the collection of Mrs. Lea, widow of the late Mr. C. W. Lea, at Parkfield, Hallow, Worcester. The plants above referred to were grown in baskets suspended over the door in the Cattleya house. There are many others, such as the true old *L. a. Dawsoni*, *L. a. Hilliana*, *L. a. Stella*, and the better varieties of the dark or typical form suspended from the roof of the house, also flowering well, clearly showing that the system followed by Mr. Hurlestone suits the plants.—H. J. C.

Miltonia (Odontoglossum) Schroederiana.—This is one of the most useful and beautiful of the autumn-flowering Miltonias. When grown

under suitable conditions, there are very few *Miltonias* that make a finer display or are more worthy of consideration. The conditions I find most suitable to its requirements are similar to those advised for *M. vexillaria*, that is a few degrees warmer than the *Odontoglossum* house during the winter months. An even temperature of from 50° to 55° meets their requirements. During the warm months of the year a light position in the *Odontoglossum* house suits it well. The potting I prefer doing in the spring, the compost consisting of good fibrous peat and living *Sphagnum* Moss in about equal proportions. The sepals and petals are almost wholly rich brown, tipped at the apex, and marbled with bright greenish yellow, the front of the lip white at first, changing to creamy yellow, the centre becoming suffused with rich purple. In the centre are several raised lines of a darker shade of purple, forming a striking contrast to the bright yellow at the base. The number of flowers on the spike is governed by the strength of the plant. I have seen as many as ten flowers on a spike where the growths have been vigorous. Some remarkably fine plants were recently noted in flower in the collection of Mr. W. Thomson, Stone, Stafford, also in the Cambridge Lodge collection of Mr. R. J. Measures.—*STELIS*.

Dendrobium formosum giganteum.—This species is usually considered one of the shortest-lived of Orchids, and is generally found to deteriorate in three or four years after being imported. It is, therefore, gratifying to find exceptional cases. I recently observed in the gardens at Gunnersbury House several plants of this, which were not by any means what might be termed strong plants when imported six years ago. Since that time they have increased in vigour, have flowered freely, and are now quite healthy and vigorous. The plants have been grown in baskets suspended from the roof of one of the Fig houses, where an abundance of heat and moisture and the maximum amount of sunlight have been obtained. The panes are unusually large and no shading has been used. There were about thirty plants in all of this species suspended from the roof of one of the houses, into which they had been removed for flowering. The remarkable vigour and condition of the plants may be judged from the fact that I counted on one large specimen sixty-four expanded blooms. The majority of the other plants had from twenty to forty flowers each, the flowers themselves being unusually large and fine in substance. Perhaps this note may be interesting to "J. T. G.," who in a recent issue of *THE GARDEN* inquired what had become of the large specimen Orchids of twenty-five years ago. These *Dendrobiums*, *Lelia purpurata* (also grown by Mr. Hudson), *Dendrobium nobile*, and *D. Dearei*, all of which have been figured in recent numbers of *THE GARDEN*, are not made up specimens, but plants that have been successfully grown on from small examples to commence with.—H. J. C.

FERNS.

SPECIMEN FERNS.

THERE are many Ferns which are rarely seen beyond ordinary-sized plants in 5-inch or 6-inch pots which may be grown on into larger specimens. To do this, it is important to select healthy and suitable young plants to start with. I say "suitable" because many form a number of crowns, and when propagated by division several crowns are often left together. The best plants for growing on into specimens are those started from a single crown. Take *Adiantum Farleyense*. A dense tufted plant may be perfectly healthy, but will never make large fronds, while one started from a single crown and grown on freely will make fronds fully 3 feet long, and it is in such that the full beauty of this fine variety is seen. After selecting

suitable plants, the next thing is to look to the soil and potting, using good fibrous loam, some stable manure, and plenty of sand with good drainage. The loam should only be broken up and used rough, while over-potting should be avoided. The plants must be potted on before getting pot-bound, and no particular season need be considered, except perhaps between October and January. Among other *Adiantums* which make fine specimens are *A. scutum*, *A. trapeziforme*, and *A. cardiochloema*. Many of the *Nephrolepis* are much inclined to get too dense. *N. davallioides furcans* makes a splendid plant when grown from a single crown. If young plants spring up round the pots they should be removed. This applies also to *exaltata* and others. All *Nephrolepis* succeed best in a stove temperature and do better in a good loamy soil than where peat is used. They do best when elevated on pots or suspended from the roof. It is only when so treated and plenty of room given that the fronds can fully develop. The greatest difficulty in growing *Asplenium Nidus* on into a large specimen is that slugs and snails play such havoc; the tiniest bite when the frond is young shows more and more as it advances in growth. To prevent these attacks place an inverted pot in a pan of water and stand the plant on this. Unlike many of the genus this does not root deeply, the roots coming to the surface, and if these are fed with a little artificial manure mixed with *Sphagnum* it will greatly add to size of fronds. The varieties of the *Asplenium bulbiferum* group are rarely grown into large specimens. *A. b. divaricatum*, though not a choice variety, makes a very handsome specimen. Plenty of pot room must be given, and almost any compost be used, provided it is not too close and heavy. As this makes such an abundance of roots, it will do no harm to reduce the ball when repotting. Until the plants are in the largest size it is intended to use, potting must be attended to before a check is given, and after the final shift manure may be used freely as soon as the roots have filled the pots. In using manure, care must be taken that it does not get into the crown of the plant, or the young fronds will be damaged. *A. laxum pumilum* is another good variety of this type.

Microlepia hirta cristata is another Fern which, to make a good specimen, must be started from a healthy young plant which has not become too dense. It is much inclined to get very bunched. By frequent division this may be avoided, and when grown on freely makes a very handsome specimen. A good loamy compost should be used, and if grown in an intermediate temperature and well exposed to the light, the fronds will be of a pleasing light shade of green. Watering must be carefully attended to. *Davallia Mooreana* (pallida), which makes such a grand specimen, is difficult to manage if once it gets unhealthy. It often suffers through insufficient drainage, the roots do not go deep, and if a little over-watered the soil gets sour. Pans are preferable to pots, especially for large specimens, but where pots are used they should be filled at least one-third full of drainage and some charcoal used. I have seen very large bunched specimens of *Gymnogrammas*, but they are far from being as handsome as those grown from a single crown, which will make much larger fronds. To succeed with these they must be grown on freely from seedlings. They like rather a rough peaty compost, and although it is dangerous to over-pot, they must not be allowed to get starved, pot-bound, or over-watered. Few Ferns are more difficult to get back to vigour if once they do get a check.

I may add that they succeed best when kept up near the glass, and the fronds should never be wetted.

Other examples might be given of those usually seen in only small plants, but which may be grown to a large size with liberal treatment, selecting good material to start with.

A. HEMSLEY.

NOTES OF THE WEEK.

Arum italicum marmoratum.—If the fruiting of this plant could be relied upon it would be worth planting for this alone. At the present time a small group of it is singularly striking, owing to the brilliancy of the scarlet fruits that cluster on the summit of the stalk.

Veronica Teucrium dubia.—Among the dwarf creeping or prostrate kinds this is perhaps the best coloured, the fine clear violet-blue being of a deep intense shade, and seen to advantage in the many dainty pyramidal spikes that the plant so freely produces. As a carpeting plant for ledges of rockwork this will be found useful.

Xanthoceras sorbifolia.—It may interest you to know that I have a seedling *Xanthoceras sorbifolia* raised by me which is now in flower. The plant from which the seed was procured, but which is now dead, flowered yearly in May. *Choisya ternata* is also showing freely for flower, but I believe that it is well known to bloom twice in the year.—W. NUTTALLSON, *Leaves*.

Lobelia British Maid.—This appears an addition to the herbaceous section of these plants, but whether it will prove an acquisition is scarcely apparent at the present time. The flowers individually are much larger than usual, but these are considerably fewer in numbers, and the effect, therefore, as a whole is decidedly less. The colour is very pleasing, a self shade of the palest salmon-pink, which is quite new among these plants.

Parnassia asarifolia.—This pretty bog-loving plant is now in flower in the moist portion of the rock garden at Kew. The flowers, which are larger than those of some other species, are of a silky white and remarkable for the beautiful green veins along the inner surface of the blooms. Occasionally the veins have a slightly feathered outline that renders the plant even more attractive. It is, however, not a plant for distant effect.

Dark Cactus Dahlias.—Quite recently two novelties among very dark Dahlias of this section have put in an appearance, and have been distinguished by an "award." These bear the names of *Ranji* and *Ebony* respectively. Both kinds are exceptionally dark, the latter perhaps the darker, as the former is lit up, so to speak, with a wine-coloured shade at the tips. In any case, darker forms than these would appear scarcely obtainable, and both are of the true Cactus type.

Aster Edith.—For this fine *Michaelmas Daisy* I have been indebted to the Rev. C. Wolley-Dod, from whose garden so many of our best new Asters have come. The flowers are considerably larger than a penny and of capital form. The colour may perhaps be best described as rosy lilac, although the shades of colouring among the Asters are almost impossible to describe in words. *A. Edith* is a good grower and gives a great number of flowers.—S. ARNOTT.

Crocus cancellatus var. cilicicus.—This pretty variety of *Crocus cancellatus* is at present fully in flower and is very effective in the rock garden. It is, I think, finer than the other forms of *cancellatus* figured in Mr. George Maw's monograph. I believe, however, that even the form named *cilicicus* is in itself a variable one with several shades of blue. The one in my garden is a good blue, approaching the ground colour of *C. speciosus*.—S. ARNOTT, *Carsethorn, by Dumfries, N. B.*

Nymphaea Marliacea albida.—This fine white *Water Lily* opened what will probably be its last flower for the season on October 8. There are buds on the same plant and on the few others of the newer *Water Lilies* I grow, but these are not likely to open now that the sun has lost much of its power and the water is so much

colder. The new Water Lilies are quite hardy with me in the S.W. of Scotland, and ought to be more largely grown everywhere.—S. ARNOTT.

Aster Novæ Angliæ roseus.—Although this Aster, as one gathers from a note in a contemporary, is uncertain further north because of its late blooming, here I have no reason to complain of it in this respect. It never fails me and gives a welcome bit of colour among the other Michaelmas Daisies. Its only fault with me is its tall habit, although this is, as may be understood, not nearly so pronounced as in stronger soils. The pretty rose-red flowers are very useful in their way.—S. ARNOTT, Dumfries.

Tunica Saxifraga.—This elegant and free-flowering little plant is even more appreciated when full of bloom at the beginning of October than when at its best earlier in the year. I saw a good plant at Summerville, Dumfries, on the 2nd of this month which looked very bright and pleasing in the rock garden there. It blooms from June onwards, and is one of the best of our alpine flowers, of light and graceful habit. The pale rose or flesh-coloured flowers are small, but their number compensates for their lack of size.—S. ARNOTT.

Leucojum (Acis) autumnale.—It was in August that I sent a short note to THE GARDEN in praise of this exquisite little Snowflake then in bloom. To-day (October 10) it is still in flower, although seeds from the first blooms have ripened and fallen to the ground. A pretty picture could be made with the autumn Snowflake were it more plentiful by planting it singly and in groups down the sides of a little dell in a large rock garden. It comes so freely from seed, that it is surprising that it is not grown in quantity and offered at a lower price.—S. ARNOTT.

Incarvillea variabilis.—The species here named is widely removed from *I. Delavayi* and others, particularly in the bush-like habit of growth, which is of a semi-shrub-like character, though not woody, but the reverse. The plant is not generally known in cultivation, and is best suited for planting on a warm border in rich sandy loam. During summer, and indeed extending into the autumn months, the plant flowers quite freely, the blooms being of a rose-carmine hue and about one-half the size of those of *I. Delavayi*. The plant grows about 2 feet or so high.

Trichinium Manglesi.—A small gathering of the flower-heads of this singular and beautiful plant were among the interesting subjects at the Drill Hall on Tuesday last, having been sent from the Botanic Gardens, Glasnevin. The arrangement of the flower-heads is very interesting, the pink-tipped segments of the perianth emerging in globular form and surrounded by long shaggy white hairs forming a head. The plant is not generally grown in gardens, and but for the care bestowed upon such things in large botanic gardens, such pretty species would soon be lost sight of.

Kniphofia Nelsoni.—I was pleased to observe a note on this Torch Lily in THE GARDEN of October 8. It is a very distinct little *Kniphofia*, which is saying a good deal in its favour, as we have now so many to choose from. Specially noticeable is the shape of the unopened spikes. These are more than usually uniform in thickness and more slender than those of most other *Kniphofias*. The colour of the opened flowers is also a good scarlet. I look upon it as rather tender, however, and would advise a little extra precaution in the way of applying additional winter covering.—S. ARNOTT.

Aster Novi-Belgii Arcturus.—In this section of the genus, the most pronounced for weedy kinds perhaps of the whole race, we find this a most telling and acceptable variety—not so much perhaps on account of its size as for the distinct shade of colour, the moderate height, and, what is given to very few kinds, distinctly coloured stems. Such a kind merits special care, and by raising seedlings and selecting, an improved type of this race may result. Of course it is even now some way behind the *Amellus* forms, particu-

larly in point of size, these latter also having the advantage of a superior habit and, not least, a stay-at-home rootstock.

Dendromecon rigidum.—The warm weather of 1898 has suited this pretty Californian shrub, and the flowering has in consequence been more abundant. Further experience, however, only confirms the original idea as to hardiness, and it will not be safe in the open unless in the more favoured districts and in warm positions. Probably in the more favoured parts of these islands it may succeed in the open, or at least with wall protection, and if so, it is well worth planting for the beautiful golden flowers that are produced for a long season in summer. The blossoms are not unlike those of a large yellow *Ranunculus*. A coloured plate of this was given in THE GARDEN of October 10, 1896 (p. 292).

Crocus iridiflorus.—Very beautiful in the early days of October is the Iris-flowered Crocus—*C. iridiflorus* of Heuffel, *C. byzantinus* of Parkinson. This year it is as fine as ever, and as it is one of the most distinct in form of any of the Crocuses, it is usually much taken notice of. The clear purple outer segments are much longer than the inner ones, which are lilac in colour, and this difference suggested to Schur that this Crocus should be separated from the others and placed by itself under the generic name of *Crociris*. It has also purple stigmata. A couple of clumps in my rock garden look very pleasing to-day with the sun full upon their flowers.—S. ARNOTT, Carsethorn, by Dumfries, N.B., October 10.

Rosa alpina alba.—The single Roses are always acceptable, and at this season the blooms of the white variety of *Rosa alpina* are especially valuable in the rock garden now that other flowers are scarce. On a sunny rock garden this Rose usually gives me some flowers in late autumn, and this year is no exception. There are, indeed, more than usual, but this is probably due to the way in which the Rose has increased by rambling among the stones, sending up suckers here and there around the original plant. This is rather troublesome, but one would rather have the work of keeping the Rose within moderate compass than be without it. The blooms last longer than in the earlier months when it usually comes into flower.—S. ARNOTT.

Caryopteris mastacanthus.—Blue-flowered shrubs are so rare, that it is a pleasure to notice one so little known or grown as *Caryopteris mastacanthus* exhibited recently at the Drill Hall. For those who have not seen it, I would like to tell of its pretty buds expanding into soft blue-lavender blossoms, light and feathery-looking, with long stamens. The shrub is very free flowering, clustered blooms growing in whorls on every shoot. The foliage is of a dull, soft green, the leaves being silvery underneath, and emitting a fragrance of lavender. A small plant of it planted here last autumn is quite a picture now when the season is throwing its veil over so many fair flowers, and even the bright and coloured foliaged shrubs are changing or losing their charms.—SUFFOLKIAN.

Gazania nivea latifolia.—The specific name here given is sufficiently descriptive to mark a wide departure from the *splendens* type, so usually associated with orange of varying shades. The above plant, however, is equally free-flowering, and when the sun reaches the blooms they are rendered somewhat conspicuous by their distinctive creamy shade. More hardy than many kinds, the above is yet of a rather tender nature, though a few degrees below the freezing point leave it unharmed. Testing such things, too, is always an interesting experiment, and in the rock garden, when flowering plants are few and far between, any good hardy species would be a welcome addition. The present year has been favourable to the *Gazanias*. Even now the above well-marked plant is quite full of flower-buds that a few hours of warm sun materially assist to unfold.

Victoria Regia at Kew.—This has been producing some large and splendidly coloured flowers

in the tank in the Royal Gardens at Kew, and the interest displayed by visitors to this house is quite remarkable. The outer or lower petals are nearly pure white, gracefully recurving to the water, the inner petals richly coloured and of a rosy purple hue, very striking by reason of the numbers so coloured, as also the general size of the flowers. The flowers, too, being slightly elevated above the surface of the water, are displayed to advantage, and therefore attract large numbers to the tank in which it is growing. On the whole, the plant this year has been highly successful, the gigantic leaves spreading to the full limit of the tank and leaving ample space for the unfolding blossoms nearer the centre.

Polygonum Brunonis.—Few free-growing dwarf hardy plants produce more satisfactory results generally than this. Happily, too, it is among the most easily grown of hardy things, soon forming a fine spreading mass, in time covered with almost endless spikes of flowers. The plant, moreover, has the advantage of looking well in foliage, in flower, and even in the waning days of its beauty the red-bronze of the multitude of flowering spikes is certainly not without its charm. The plant, if not essentially a rock garden subject, is nowhere seen to so much advantage as when covering a lofty and spacious ledge of rock, where opportunity is afforded for spreading out its free carpet of narrow lance-shaped leaves and sending forth its myriad spires of pretty, if small, blossoms. It never fails to flower, while its absolute hardiness should render it of service in many a large garden where space exists for such things.

Hybrid scarlet Lobelias.—Mr. Ladhams, of the Shirley Nurseries, Southampton, sends us some good hybrids of these, a very varied and interesting series. Many years ago certain forms of the larger scarlet *Lobelia* were raised, and they were very popular at one time, and now we see a revival of interest in them and some attempts made to improve them. MM. Rivoire, of Lyons, have raised some handsome hybrids between the blue *Lobelia* of the American river banks and the large scarlet *Lobelias*, some of which are pretty in colour also. Usually these hybrids have not been real improvements, but some of those raised at Lyons are much better than the old ones. The true cardinal flower is a hardy perennial, a native of the Eastern States of America, in moist soils. The plant that gives us the finest garden varieties is *Lobelia fulgens*, a native of Mexico. Although the plant grows well in summer in our gardens, it is somewhat tender in winter. We mean the varieties of this greater scarlet *Lobelia*. Round the coast, in light peaty soils, in the west country and in Ireland it often lives over the winter, but in inland districts and cool soils it must be kept in frames, as out of doors it often perishes in winter.

Chrysanthemums in Egypt.—Since 1894 *Chrysanthemum* cultivation in Egyptian gardens has gradually been finding favour. Its claim as a popular favourite has drawn from admirers some of the attention it so well deserves, and the propagation, manuring, and disbudding of the plants are gradually being mastered by the Arab gardeners. The few poor varieties occasionally met with are giving place to a larger number of healthy, well-grown specimens; so much so, that last autumn the first *Chrysanthemum* shows in Egypt were held in Cairo and Alexandria with creditable results. This season *Chrysanthemum* shows are again to be repeated, when greater results may be expected. Many amateurs in the Egyptian capital have obtained cuttings and plants from England and France, and are growing *Chrysanthemums* in considerable numbers. The Government Gardens at Barrage, the *Chrysanthemums* from which were awarded the silver medal at the Cairo show last autumn, have this year a special *Chrysanthemum* garden of some 5000 plants, and private growers in Alexandria and other towns in the Delta are doing much to establish this home favourite in Egypt.—WALTER DRAPER.

STOVE AND GREENHOUSE.

CAMPANULA VIDALI.

The accompanying illustration shows a group of this strange and beautiful shrubby *Campanula* grown for seedling at Ardeairn, the nursery grounds of Mr. Hartland, near Cork. It was discovered many years ago by Captain Vidal, R.N., on a rocky islet off the coast of Flores, one of the group of the Azores, and has been figured in the *Botanical Magazine*, t. 4708. It received a first-class certificate when a group of well-flowered plants was shown at a meeting of the Royal Horticultural Society at the Drill Hall. Being a perennial, the plants flower the second year from seed. The group of plants figured here was plunged out of doors for blooming, having been raised and grown in a cool frame. It would probably survive any

culture, rooting readily from cuttings of the young shoots during the spring months, and they grow away freely afterwards if given the ordinary treatment of stove or intermediate house plants. —H. P.

Fuchsia gracilis variegata.—This is a counterpart of the old hardy *F. gracilis*, except that the leaves are variegated with creamy white. This *Fuchsia* may be advantageously employed for several purposes, it being one of the most desirable subjects that we have for clothing the roof of a greenhouse, the slender shoots disposing themselves in a very graceful manner, and towards the tips they are quite weighed down with their brightly coloured blossoms. Fair-sized bushes, too, planted out of doors during the summer are very beautiful, but in most districts it will be necessary to place them under cover in the winter, as the variegated variety is less hardy than the typical green-leaved kind. It is quite an old plant in gardens, that might with advantage be more often met with than it is. With the

structure or any similar position, but for general purposes it is far more useful in the shape of smaller plants. There are several forms, but this (the oldest) is equal to any of those with scarlet berries, while one with yellow berries (flava) may be grown for the sake of variety, but it is not nearly so showy as the other. *Rivina humilis* is a native of the West Indies, and in some districts quite a weed.—T.

CAMELLIAS.

To the interesting article on Camellias that accompanied the plate in last week's GARDEN I should like to add with respect to Donckelaari the great variability in its markings in different seasons. Whether this is due to more or less sunshine, more or less vigour in the plant, or any other cause I am unable to say. It is certainly the case not only in this variety, but in other old sorts like Cup of Beauty, japonica, pomponia, and others. The very late growth of Donckelaari is quite as pronounced under glass as in the open, and in a house containing many old varieties it is one of the last to start into growth and the last to drop its flower, although the plant is on the south side fully exposed to the sun and quite without shade at any time of the year. So far as size is concerned, conspicua is with me quite as large as reticulata, and in its case the large yellow stamens contrast finely with the bright-coloured petals. A few varieties were planted outside some years ago, probably late in the fifties or early in the sixties, but they are not satisfactory. They are not affected by the sharpest winters; buds are produced in plenty and flowers develop, but only partially, and in five seasons out of six come to a premature end, spring showers and frost being responsible for the damage. Under cover, with just enough fire-heat to keep the glass above freezing point, they flourish exceedingly, and some of the plants with the dark glossy green leaves and plenty of firm, plump buds are doubtless those with which the house was furnished close on 100 years ago. There was a tinge of yellow in some of the foliage and a tendency to ragged, irregular growth when I took charge of them sixteen years ago, and a general renovation of the beds was suggested, but remembering, from early perusal of old gardening books, the thoroughness that characterised the work of our fore-

Campanula Vidali at Ardeairn, Co. Cork. From a photograph sent by Mr. W. B. Hartland.

ordinary winter in the southern districts of England and Ireland, but has not yet been put to that test by Mr. Hartland. It is a most distinct plant, and desirable for conservatory decoration. —B. P.

Ruellia rosea.—This is a free-growing plant of a half-shrubby character that keeps up a succession of its showy blossoms for a considerable period. The flowers, which are of a bright rosy magenta colour, consist of a curved tube about $1\frac{1}{2}$ inches long, while the expanded mouth is an inch or so across. It is a native of Brazil and succeeds well in an intermediate temperature, while it may also be treated as a stove plant. The individual flowers do not last long, but they succeed one another so quickly that a plant has generally a fair sprinkling thereon. This and other *Ruellias* are well worth more attention than they usually get. They are all plants of easy

exception of the much larger-leaved variety Sunray, it is certainly the best variegated variety that we have, and the two are so dissimilar that in most gardens a place may be found for both. —H. P.

Rivina humilis.—This is an extremely pretty decorative plant, for though the flowers are insignificant, the berries that succeed them are borne in such numbers and are so brightly coloured, that a few good specimens form a very pretty feature in the greenhouse during the latter part of the summer and in a warmer structure later on. It can be readily increased either by means of cuttings or seeds, and forms a slender, loose-growing plant if allowed to assume its natural character, under which conditions it is far more pleasing than when stilly trained and tied. A stick or two just to afford the necessary support is all that is needed. This *Rivina* can also be employed to furnish the end of a glass

fathers in the way of first preparation, I came to the conclusion that liberal feeding would bring them round, and, after a little pruning and tying in, gave them a mulch of fresh cow manure 3 inches thick, and a dose annually repeated ever since. They responded well to the treatment. The foliage was soon in the best of health, and in the majority of seasons I get plenty of flower from the end of November until early in May. In drawing attention above to the little done in the way of renovation of borders, I did not mean to suggest that no measures had been taken in this direction from the time of planting; they were doubtless overhauled some time in the fifties. Nothing, however, has been done since 1866, and this is an instance of the minimum of trouble in connection with planted-out Camellias, always provided they get the necessary attention in the way of annual mulching and a copious supply of water at regular

intervals, these intervals varying in my case from once in ten days in summer to once in twenty-one in winter. I have only just finished bud-thinning, some of the varieties being very late in swelling up. It is a tedious operation with old-established plants, six and seven terminal buds, and as many as a score on a shoot some 9 inches long, not being at all out of the common. I generally leave one terminal bud and another about 3 inches or 4 inches down the shoot, a method that ensures a nice succession of flower. E. BURELL.

POINSETTIAS.

The bright red bracts of these plants are very useful for all kinds of decoration in winter, but although they are a good deal grown in private gardens generally, the specimens produced are not always a credit to those in charge. Yet their culture is extremely simple if gone about in a proper manner. By cool treatment and judicious feeding market growers produce plants with large bracts a foot or more across and about the same height in quite small pots. One of the worst mistakes is keeping the plants always in heat; it does not matter so much of course if they are not required very dwarf, but plants 1 foot or 15 inches high come in useful for many purposes where the lanky specimens often seen would be unsuitable. The dwarf plants, too, carry their foliage almost to the surface of the soil, while the tall ones have very often a foot or more of bare wood, which detracts a lot from their appearance. Large spreading plants are not often needed, but if they are, the old plants should be cut in early and started in warmth, but when the young growths are 2 inches in length they may be placed in a greenhouse temperature, a good place being a nice light frame where a little heat can be turned on at night and during cold or wet weather. The hardier the plants are grown the more solid the growth will be, and as a result the bracts will be fine in size and colour. Stage the plants on pots or in some other way so that the heads are within a few inches of the glass, and lower them by degrees as the growth advances. Cover the glass by night as long as there is any danger from frost to be apprehended, but on mild nights allow a little air on the top of the frame. In sheltered gardens the lights may be entirely removed by midsummer, the plants meanwhile being thinly arranged so that the air plays freely about every part of them, keeping the growth stocky and short-jointed, the individual leaves meanwhile being large and of good texture. As a rule it will not be practicable to put the lights on again over these large plants, consequently by the end of August they will have to be housed in some light and airy structure, such as an early vinery cleared of its fruit. Of course, where pits of suitable size and depth are at command, these may with advantage be used, and, owing to the heads of the specimens being close to the glass, they will do admirably. Even here it is worth while being at a little trouble to adjust the plants as to height, though the plants if kept cool will only grow slowly and will not draw, while when the bracts show, the stems do not elongate much afterwards.

To obtain the dwarf plants mentioned, recourse must be had to annual propagation, and the stock plants should be kept dormant as long as possible. When signs of growth appear get them well up to the light, and while keeping the roots on the dry side let the atmosphere be genial, occasionally damping the plants lightly overhead. The shoots will keep nicely short-jointed, and by the middle or end of April should be about 3 inches or a little more in length, firm at the base, yet not woody.

This is the time they will strike most easily and with least heat. They may be rooted in 4-inch pots, three cuttings in a pot, or, better still, singly in 3-inch pots. A slice of old wood or a slice of bark may be taken off with each one, and this keeps them from flagging unduly. When striking them singly they should be inserted by the side of the pots, as they are more likely to root here than in the middle, and at subsequent repotting this can easily be rectified by pressing the ball flat and filling around it. The less bottom-heat they get the better, only enough to ensure their rooting, and as soon as it can be seen that they are struck, take them by degrees to a cooler and drier house. If not allowed to make any growth in the propagating frame they are not very susceptible to checks, but this requires watchfulness and a little observation. Those acquainted with the plants can see easily when the cutting is rooted, but beginners are apt to leave them too long. They need not be long in the cutting pots, and from these may go into the flowering size. This will be according to the strength of the plants, and will vary from 4½ inches for the smallest and latest to 7 inches for the best. A very rich compost is not desirable, equal parts of loam and rough peat, with a little of a good concentrated manure and a dash of sharp silver sand, suiting them well. From the time they are established in these pots the plants may be grown almost entirely in the open, covering them only from heavy rain or hail. Keep the pots well apart so that sun and air play freely about them, and water with care until the pots are filled with roots, an abundant supply being necessary afterwards. Feeding may commence when the plants are a little pot-bound, and continue until the bracts show colour. Soot-water well diluted and used frequently has an excellent effect upon the colour of foliage and bracts, and this may be alternated with guano with advantage. The bracts open, lessen the water supply a little and take the plants to the conservatory, or wherever they are wanted, this class of plant being much hardier than others grown in a stove temperature all the season. In winter they may be dried off by degrees and placed in a fairly warm house, or anywhere where the temperature at night does not fall below 50°. It will not, of course, be necessary to keep all the plants if an annual system is decided on, but it is wise to keep enough, and fairly old plants are better for stock than young ones.

PLUMBAGO CAPENSIS.

In spite of the frequent notes on this lovely greenhouse climber, it is not seen in amateurs' houses half so often as it should be, and, unfortunately, when it is grown it is far too tightly trained, being tied or nailed in instead of allowed to ramble at will. I know of nothing more beautiful than a large plant allowed to take its own way, and after being cut back into shape a little in winter, to push its shoots in all directions, to be crowned presently with the lovely pale blue flowers, so different from almost every other blue flower in cultivation and contrasting so beautifully with the deep green foliage. It is as easily grown as it is beautiful, making immense plants in a short time where there is room for its full development. The finest possible position for it is in a large and lofty conservatory, where in summer it makes a grateful shade for the other occupants of the house, and, being cut fairly hard back in winter, does not obstruct the light. Besides the rafters of the roof there are often pillars, tie rods, and other places in houses of this description it is necessary to drape with flowers and foliage, and there is no better place for the Plumbago. Where it is desired to cover a

large space quickly, the plants should be put out in a fairly large and rich border and encouraged by a gentle warmth and moist atmosphere to make plenty of growth, ripening this well by exposure to sun and air in autumn and only removing the weak and unripened points. When the plants have filled the allotted space and the wood begins to get old, it is good policy to train in a few young shoots to take the place of these, cutting the oldest away annually. Even in small amateurs' houses there is no need to be always tying and nailing the plants hard back to walls or on balloon trellises. Give them liberty as far as space will admit, and the result will far exceed the expectations of those who know it only as a trussed-up, tightly-trained captive. There is a white form of this plant now plentiful in gardens, and in some cases the two plants are grown together, but this, I think, is a mistake. We have plenty of white flowering creepers and climbing plants, but only one of this colour. I do not wish to be understood as decrying the white form: far from it, but to grow them side by side is unnecessary. Both are very fine plants, but the blue form is indispensable. It may be propagated by cuttings, choosing those that are only half ripened and are not showing flower. They root readily in a light, sandy compost, and often the young suckers that spring from the base of an old plant may be taken off with roots attached and potted in light, sandy soil. The plants must be kept rather dry at the root during winter. H.

ARUM LILIES TURNING YELLOW.

COULD you give any information why Arum Lilies turn off yellow round the edges of leaves after being potted? Mine grew strong and healthy plants, were carefully taken up, well looked over for worms, potted in nicely-prepared earth, sifted and mixed with rotten stable-yard manure, and put into a shed for a few days. All are now, with the exception of one, looking sickly and turning yellow. They have been well watered with plain water and kept in a greenhouse, but have never recovered potting, which was done about three weeks ago.—E. A. T.

** It is difficult to say positively what was the actual cause of "E. A. T.'s" Arums going as described, though the experience is not unique. Evidently the plants had a severe check at lifting time or immediately after, and the result of a check always shows itself by the leaves turning yellow just round the edges at first, and gradually the whole leaf assumes the same colour and dies outright when the check has been very severe. Probably by this time the plants have recovered somewhat and no further decay will take place, but they will remain unsightly, and the loss of foliage will affect the flowering more or less. The check may have arisen from one or more of many causes—over-mutilation of the roots, too much or too strong manure in the soil, insufficient drainage, over-watering, or too airy quarters after lifting. Either of these suggested causes would check root-action for the time, and this on such a strong and gross-growing plant as the Arum at a time when it should be in full growth is bound to affect the leaves already made, and which cannot get supplies quick enough to keep them growing. Plants grown on the system of planting out during summer require very careful nursing after lifting, and this is only possible where a good deep pit or garden frame can be given them, and to prevent rapid evaporation very little ventilation should be given until they are seen to be growing again. Raw manure coming into contact with broken roots checks new root growth for the time, and it would have been better to have used no manure at all in the soil round the roots and to have used it later on as a top-dressing. Over-watering, too, would tend to stop root-action, for though the plant is a semi-aquatic, it cannot assimilate much water until the roots regain activity, and wet soil, especially when well manured, soon turns sour if not occupied with active roots. I should strongly advise "E. A. T." to adopt another system next year,

as that of planting out is by no means the best, though, when well carried out, it produces the largest flowers, but fewer of them and later, than if the plants were grown in pots throughout.

Shake out the crowns in June or July, pull away the smaller offsets and repot at once, either single crowns into 7-inch pots or more into larger ones, according to whether big or small plants are wanted. The soil should be rich, and as there is practically no growth at that time to support there is no fear of a check being given. When the new growth spears up, keep well watered and in a fairly sunny spot, the pots being stood on a bed of ashes, leaving them there all summer and removing them to the greenhouse early in September if flowers are wanted before Christmas, or they may be left outside till the nights begin to get frosty if they are not wanted so soon. These plants should have lots of manure water from the time the pots get full of roots, and it is well when bringing them under glass to remove some of the top soil and replace it with semi-decayed cow manure, built up basin shape to allow for plenty of water. A modification of both systems may be made with good results by potting as above and then plunging into the open ground in trenches, just burying the pots with soil and allowing the plants to root through into the soil beneath; this will be accelerated by making the holes at the bottom of the pots bigger before plunging. This is a very good method for those who cannot attend to pot plants with water whenever it is needed, as it reduces the needs in that way, also the plants so grown may be depended on to do well for two years in the same pots provided the autumnal top-dressing is not neglected. The planting-out system, though sometimes successful, is most unnatural, as the plants must get more or less of a check at the very time when they should be making rapid progress towards flowering.—J. C. T.

CULTURE OF STEPHANOTIS.

The notes by "H." and "E. J." (page 234) on the management of this flowering climber are interesting and instructive. I quite agree with the former as to the desirability of limiting its root space. One of the best examples I ever saw was grown in a large pot which it had occupied for some years. The plant was trained to the back wall of a Pine stove, all the shade it had being a sprinkling of whitening over the roof. Growth was thinned out every year and the rest trained, several growths to each wire, and in a somewhat limited space hundreds of trusses were produced annually. The assertion that much manure in the soil is not advisable is, I think, also correct. The compost the plant referred to grew in consisted of three parts good turfy loam and one part peat—also of a fibrous nature—together with a free addition of charcoal and mortar rubble. Mealy bug was somewhat troublesome, but a remedy was found in the N. L. All fumigators, one of these being occasionally set in close proximity to the plant. As regards temperature, I think it is very accommodating, although I should not care to treat it too much like a greenhouse plant. Many will remember the splendid specimens which used to be shown at the London exhibitions some years ago, these being grown in a stove temperature. I know the Stephanotis will winter in a very low temperature provided the roots are kept quite dry and the house also. Some years ago a friend of mine living at Beekenham had a large plant under his charge. It occupied a small, badly-heated structure, and often in severe frost the temperature at night approached freezing point, yet the plant took no harm, and was each summer a dense mass of pure white trusses. Another very striking proof that the roots do not require a lot of rich soil may be seen at Hillside, Newark. In a small span-roofed stove, running east and west, is a very fine plant, growing in a brick pit only a few feet square. Here it has been for many years, deriving its chief support from top-dressings and manure water. In early summer the bloom is worth going a long distance to see.

The plant is trained pretty close to the glass and receives little or no shade. No doubt the less heat the plant has the less liable is it to mealy bug, the trusses also lasting longer when cut.

NORWICH.

FLOWER GARDEN.

ASTILBE GERBE D'ARGENT.

(SILVER SHEAF.)

This distinct and handsome form of Astilbe, which gained many admirers at one of the Drill Hall meetings towards the end of July, is of

Astilbe Gerbe d'Argent (Silver Sheaf). From a photograph by Mr. J. Gregory, Croydon.

hybrid origin, and was raised by M. Lemoine, of Nancy, its parents being *Astilbe Thunbergi* (introduced from Japan by Messrs. Veitch in 1880) and the plant generally known in gardens as *Spiraea astilboides floribunda*. In general appearance this newer form is about midway between the two, reaching as it does double the height of *Spiraea astilboides floribunda*, being altogether a more select plant and of much greater ornamental value than *Astilbe Thunbergi*. The blooms, which are borne in large plume-like, terminal panicles, are white, with a

slight pinkish tinge on the exterior, while the stamens being also of the same hue, the flowers seen in a mass appear to be slightly suffused with pink. Though sent out by M. Lemoine under the name of *Gerbe d'Argent*, the English translation thereof (*Silver Sheaf*) is generally applied to it. The *Astilbe* in question forms one of a group of three, which were first distributed in the autumn of 1895. The name of A. Lemoinei was applied to the entire group, and the three were announced by M. Lemoine as forms of it. The general aspect of the members of this section is well shown in the accompanying woodcut, the difference between them not being very strongly marked. In addition to *Gerbe d'Argent*, the varieties distributed at the same time are *Panache*, a rather looser and more slender grower, and *Plumet Neigeux*, somewhat dwarfer and more compact, with whiter blossoms.

These *Astilbes* are certainly of a mixed origin, as *Spiraea astilboides floribunda* was obtained by the intercrossing of *S. astilboides* and *S. japonica* (of gardens). The nomenclature of this class of plants is in such a confused state, that one is in doubt whether they are *Spiraeas*, *Hoteias*, or *Astilbes*. This last name is certainly the most suitable for members of this section, and that of *Spiraea* should be discontinued altogether for this class of plants, as it leads to no end of confusion. A good illustration of this is furnished by the name of *Spiraea japonica*, which rightly belongs to a shrub often known as *S. callosa*, yet it is far more frequently applied to *Astilbe japonica*, or *A. barbata* as it is sometimes called.

The cultural requirements of *Astilbe Gerbe d'Argent* are the same as needed by its immediate allies, viz., a good deep soil that is at the same time cool and moist. Around the margin of a pond or in some low-lying spot these *Astilbes* are seen at their best, that is when they are sufficiently established to form large clumps, for it is the bold and striking contour of these that is so much admired, and in small plants this feature is to a great extent wanting. They are perfectly hardy, and can be rapidly increased by division. M. Lemoine says his varieties will force as well as *A. japonica*, but it is as outdoor plants, in position such as our own native *Meadow sweet* will flourish in, that their great value lies. H. P.

Calceolaria alba.—This neat and pretty species is still flowering freely from plants put out quite early in the year, and what is of equal import is the likelihood of the earliest trusses providing a fair amount of good seed. The latter will prove of considerable service, as there has been some difficulty, not so much in securing cuttings and rooting them as in keeping the plants through the winter. Not unfrequently do lifted plants of such things perish during the cold season, but it is another matter when fresh young cuttings perish in a wholesale sort of way.

Stokesia cyanea.—Stokes's Aster was in bud the other day in the garden of Mr. John Maxwell,

Maxwelltown, Dumfries, but although in this stage, it is not likely that it will open before being cut down by frost. It is unfortunate that this *Stokesia* is so late in coming into bloom unless forwarded before being planted out, as so fine an autumn flower would be appreciated even among the numbers of beautiful *Starworts* we now possess. It hardiness is beyond question with us, so that those who exhibit it among hardy border flowers consider themselves justified, although the blooming time has been anticipated by growing and flowering it under glass. I recollect coming across it in a Clydesdale town some years ago just coming into flower at the end of July. It was growing in a greenhouse, and was to be included in a stand of hardy herbaceous flowers in a show at the beginning of August. It is to be feared that doing this was likely to lead to disappointment on the part of some who saw it and thought it had been grown outdoors.—S. ARNOTT, *Carsithorn, by Dumfries, N.B.*

NOTES ON CARNATIONS.

THE present season has not been at all favourable to these flowers in the open, at least on a hot, dry soil. What blooms I had were small and much disfigured by thrips. In a mass they certainly looked showy, but anything like a trial of varieties was not possible. Perhaps the crimson-coloured *Mephisto* was an exception, this sort proving very sturdy in battling against insects and drought. The whites and yellows were dirty-looking, and fancy striped ones anything but nicely marked. Under glass, however, the blooms opened well, but late, and owing to the extreme heat a short flowering season followed. A type rapidly gaining in popularity is the yellow-ground *Picotee*, and many very handsome varieties may now be had, but it struck me, at exhibitions as well as in my own collection, that the newest kinds, with some exceptions, are too large. Personally, Mrs. Robert Sydenham appeals to me as the best of the class, and this kind has been cultivated some years. Mrs. J. Douglas is another old sort which, like the first-named, is rich in delicate colouring and has petals of first-rate quality. Neither variety grows very large. Countess of Jersey is another of the older division and is a charming kind. *Voltaire* is one of the later-raised varieties, of rather large size, but very beautiful; so is *Eldorado*. *Ladas* is pretty, but somewhat small. *Golden Eagle*, not so good this year as it was in 1897, is a very fine yellow ground. *Stanley Wrightson*, a new heavy scarlet-edged bloom, appeared most distinct and handsome, and *Miss Alice Mills*, not so highly coloured, is still a choice new kind. *Mr. Nigel* is a crimson-edged flower, of striking appearance. A newer kind, *Hygeia*, seems likely to find a place among the best. It is a delicate rose-edged flower, of capital quality. *Dervish*, again, should be added to the smallest collections. This is a light-edged bloom, of great richness. Yellow-ground *Picotees* have strong grass; they are therefore of easy culture, and generally the most admired by visitors. New sorts of sterling worth have also been added to the class known as *fancies*. *Cardinal Wolsey* and *Geo. Cruikshank* are notable types. *Monarch* is very fine. This, I believe, originated in Germany, whence came that grand yellow *Germania* and splendid scarlet *Grandeur*. I like *Perseus* very much. This is a distinct flower, the ground colour buff-yellow, edged red; in quality it is excellent. *Hidalgo* was exhibited well, and is a splendid fancy, but it will be some time before it is generally grown, the stock in existence being so limited. *Garville Gem* is a great favourite, the heliotrope shade being much admired. As an exhibition kind, however, it is too flimsy. *Don Juan*, purple streaked on a buff ground, is a handsome bloom of large size.

Among self-coloured Carnations the most distinct gains are *Endymion* and Mrs. James Douglas. Perhaps one should add *Lady Hindlip*, a splendid scarlet. The first-named is salmon-pink, a delightful shade, the shape and quality of

flower being perfect. Mrs. James Douglas, carmine-rose, is equally fine in shape; the petals thick and handsomely placed. Mrs. Eric Hambro, a pure white kind, is still unsurpassed. Among blush-white Carnations, *Her Grace*, *Seagull*, and *Waterwitch* are the three best, to my thinking, in the order named. *Germania* and *Britannia* are very fine yellow varieties. Both *Corunna* and *Miss Audrey Campbell* are good. I am not particularly struck with the new *Regina*; the blooms have nice quality, but the growth is rather weak. A pink sort of fine shape and colour is *Exile*. *Braw Lass* is good. *Bendigo*, a purple shade, was not so fine with me this year; it is, however, most distinct. Among crimson, *Topsy* is of fine size and colour, with rather weakly constitution; *Mephisto* is, therefore, the better generally, as it is a strong grower. *Nox* is a new and very dark kind—a first-rate gain. Mrs. Colby Sharpin has scarcely had a fair trial with me, but I fancy it is the best of the cinnamon or apricot shades. *Winifred* is also very fine. The *Pasha* is discarded; nor is *The Hunter* so good as desirable. *Nabob*, again, is hardly an improvement in the shade of colour first known in the popular variety, Mrs. Reynolds-Hole. *Carolus Duran* will be discarded; it is a sorry-looking kind as I grow it. Mrs. Grey Buchanan is a new sort in this delightful shade likely to prove good. First-class scarlets are *Hayes' Scarlet* and *King of Scarlets*. *Grandeur* is very fine, perhaps better than either, but not of over-strong growth. Mrs. McRao also is a good new kind.

Layering this year is later than usual. This may be a subsequent advantage, as roots quickly form when the grass is well ripened, and I do not care for the young plants to make much top before the winter sets in. H. S.

HARDY WATER LILIES AT GUNNERSBURY HOUSE.

AT *Gunnersbury House Gardens* may be found, under Mr. Hudson's charge, the most complete collection of hybrid Water Lilies that has been brought together during recent years. The collection now numbers some three dozen varieties, several of which have been added within the last year or so. Of the gardens generally I do not wish to speak now, preferring rather to direct attention to the above subject with some passing observations on the progress of those kinds originally planted out in the lake here. This lake is almost an ideal spot in which to cultivate these lovely aquatics, with here and there huge masses of *Bamboos* on the very edge of the lake, the roots thereof taking in their fill of the moisture and rich mud that have played so large a part in making them what they are to-day. Of the Water Lilies themselves, would-be cultivators will doubtless learn with satisfaction that some of the earliest planted have now spread out into huge masses, of which the foliage alone is a sight to behold, so abundant and so dense has it become in a few years. Some of these masses are now many feet across, and, judged by the standard of some fine blocks of the old white kind at either extreme of the lake, may safely be regarded the equal of the old kind both in vigour and in freedom of growth. So large indeed have some of these early masses become, that it is a question whether a division of some of them would not be attended with greater freedom of flowering. This is suggested rather for the better display of the blossoms and the possible effect derivable therefrom by spacious grouping of the kinds than from any possible notion that as yet—though of course this is possible in time—the plants are in themselves overcrowded. Even if they were, nothing could be more gratifying in so short a time. As I saw these original clumps a year or more ago, I confess I could not conceal my surprise at the

progress the plants have made, a fact alone which speaks volumes for the vigour of these lovely hybrids. Indeed, this innate vigour is of an importance as supreme as that of hardiness, for without these essential qualities, the new colours and lovely flowers would have been worse than useless to our gardens. But as the facts are, their value to our gardens is only greatly enhanced, opening out, as it were, an entirely new era for aquatic gardening the possibilities of which cannot now be foretold. This much, however, is obvious, for these lovely floating pictures in the landscape will in the future appear where only the waters of the pond or lake in the past met the eye, and these not always in creditable form.

All this is apparent at *Gunnersbury*, and here at least will be found a water-garden for those who dwell near London rich in the treasures of this race of plants. That it is even now rich in these lovely hardy *Nymphaeas* may be gathered from the fact of existing numbers alone, the majority of which are novelties, and not a few of them very rare at the present time. Since my last visit many beautiful things have been added. This is apparent in two ways; first, by the small size of the plants themselves, and, secondly, by their nearness to the margin of the lake, where, it may be said, all new-comers are located at first. At the sides the water is shallow, and deepens with the outward distance till some 6 feet or so is reached. Many of the fine masses referred to are already in 3 feet deep of water, and right well have they succeeded. There is this consolation, that such things grow apace in a remarkable way when in suitable water, and, of course, provided such unwished-for things as water-rats are not at hand.

Some of the more recent additions to the collection here are *Ellisiana*, a fine purple-carmine, very brilliant in shade; *Gloriosa*, another of a similar shade, but very rich and dark; *Lucida*, almost vermilion in the striking shade of colour; *Mariacea flammea*, reddish purple, flushed with white; *M. rubro-punctata*; *Caroliniana perfecta* and *C. nivea*, the former salmon, tinted flesh, the latter white, and both exquisitely fragrant; *Odorata exquisita*, handsome foliage, and rose, carmine, white, &c. Several of these, it will be noted, have flowers of a remarkably brilliant tint of colour, and the effect of such things in the water in goodly-sized patches can scarcely be conceived. The range of colour, too, and the varying tints combined in certain flowers are remarkable, many kinds being extremely chaste and, what is equally valued, delightfully fragrant. Nor is it a flower or two and then past. Far from it, seeing they yield a succession of blooms for many weeks in succession. Viewed, too, from the practical side, these things will come as a boon equally to the gardener of the future as of to-day where an unlimited supply of flowers has to be maintained for furnishing tables and the like. For such work these hardy *Nymphaeas* will certainly prove unique flowers unequalled for their beauty and suitability, abundantly produced, too, with no care or thought of annual preparation or propagation, or requiring elaborate glass erections to bring them to perfection. E. J.

The Florida Velvet Bean.—There is much in a name, and this plant has had considerable attention attracted to it of late, materially arising from its attractive designation. Some time since I had occasion to ask Mr. W. Watson, of Kew, for information respecting this Bean. Mr. Watson said that "The Florida Velvet Beans are seeds of a species of *Mucuna*, possibly a cultivated form of *M. pruriens*. They are also grown

in the Mauritius under the name of *Pois Mascari*. We have plants growing at Kew of the Florida Bean, and when they flower the species can be determined. The seeds are like those of *M. pruriens*, which is a tropical annual and is grown in India as a fodder plant. It is probably as hardy as the Scarlet Runner. Whether the true character of this Bean has since that time been determined at Kew I do not know, but possibly Mr. Watson will kindly enlighten us. *Mucuna pruriens* is known as Cow-itch, having stinging properties. The appellation is an ominous one as to the usefulness of the Florida Bean if it possesses the same irritating properties. It seems as if someone wanted to push this plant into notoriety, but what will thrive well in the tropics may be but a poor plant in England.—A. D.

Striking Geranium cuttings.—Very many gardeners place their boxes or pots containing cuttings of Geraniums by the sides of garden walks or in some other open position, and the plan answers very well so long as the cuttings are taken in good time and the weather remains fine. It often happens, however, that cutting-taking is postponed till as late a date as possible, gardeners not liking to mar the appearance of the flower garden, and the cuttings if placed out of doors do not stand such a good chance, especially if the weather sets in wet. Many of the cuttings decay at the base, others rooting indifferently and withering badly. The best and safest place is a cold pit or frame. The lights can then be drawn over them in rainy weather and still plenty of air given. Another thing frequently receiving too little attention is the compost the cuttings are put into, some seeming to think that anything will do for Geranium cuttings. In close soil, which becomes closer still from repeated waterings, roots form but slowly; whereas if a fair quantity of leaf-mould and coarse sand or grit is added, they callus and root in a minimum of time. Such plants make speedy growth when potted off in spring; whereas badly-rooted cuttings can never make up for lost time, and are always an eyesore in the flower garden.—J. C.

KITCHEN GARDEN.

POTATOES.

WHERE ground has been well cultivated and manured the Potato crop is a good one on the light sandy soil of this neighbourhood, but on many of the allotment gardens and in fields, where planting was late and ground poor, hardly any top-growth was made and the crop is light. In gardens under good culture the tubers are very fine and plentiful, and there will be with most varieties a difficulty in obtaining enough medium-sized tubers for planting. Though disease appeared very early and the haulm was rapidly blackened during a week of wet weather, the crop was then fully grown, and the extreme drought which supervened more than a month ago, and has continued till now, arrested the spread of disease to the tubers of late sorts, so that they now lift clean and good. Opinions vary greatly as to whether planting should be carried out early or late, but the results in either case are governed by the kind of growing season in store, and no set rule can be followed with a certainty of being the best. In some years supertuberation, which spoils the quality of the crop, is prevented by late planting, and the medium-sized tubers then obtained are more valuable than the big and ugly ones coming from early plantings, but this year the earliest planted have given by far the best crop, and as there has been no "growing out," the tubers are handsome in shape and clear in skin. Perhaps the best way to ensure good quality for home use is to plant one half the main crop in March and the other half at the end of April. One or the other

lot will then be suited by the season whatever it may turn out. Lifting is now completed here, and I am able to give some report of the relative value as to cropping of the varieties grown.

Among earlies, the only one of the Ashleaf varieties now grown here is Veitch's Ashleaf, and this has turned out particularly good, giving a much heavier crop than it usually does. Sutton's Ringleader and Duke of York were magnificent, but the former of the twain takes the disease too freely and too early to please me; indeed, during the cold days and nights of May and early June some of the frame-grown plants of this variety developed it, a thing I never knew to happen under glass before. It did not spread much, but the smell and appearance were unmistakable, and a few of the tubers turned out badly affected. English Beauty, a rather new second early, merits its name, being very handsome and a good cropper, but the quality here was quite third-rate, a failing that very handsome-looking varieties too frequently have. With Snowdrop I am rather disappointed this year. I have for some years made it a standard variety, its quality being of the very best, and the season over which it is available and good being longer than that of any other Potato I know. I never saw it make better growth than it did this year, and the plot on which it grew looked better and more even than any other in the garden, but the tubers, which are never more than medium sized, have turned out decidedly smaller than usual, so that they do not bulk at all well. Probably this variety is following in the footsteps of another medium-sized variety, Covent Garden Market, of which I thought and wrote very highly for some years, but which was eventually discarded owing to showing signs of wearing out.

Medium-sized Potatoes are the best for eating, but when the varieties which have produced them take to dwindling below the size which can be so described, they are expensive to grow and wasteful of ground. My experience is that many, if not all, Potatoes wear themselves out in some soils, and that they may be retained too long to be profitable. Windsor Castle is the best second early I grow, taken at all points, and has given a grand crop this year. Its quality is first-class in spite of its being a large Potato. Unfortunately, it is rather susceptible to disease, so that it is not to be entirely depended upon. After discarding the old American variety Early Rose some years ago on account of its tendency to disease, I was tempted to grow it again this year, but shall not repeat the experiment. It is a fine cropper and very good eating, but these qualities do not compensate for the loss of half the crop.

Among main crop varieties, Syon House Prolific sustains the good character I gave it last year and is again splendid. Another from the same source, Syon Main Crop, grown for the first time, shows no extra cropping qualities here, and has not yet been tested for quality. It turned out a fair crop of large pebble-shaped tubers, but it must have a further trial before its value is fully ascertained. Carter's Snowball is a fine quality main crop variety of good appearance, but it has never proved a heavy cropper here. Sutton's Main Crop is a good cropper, but inferior in quality. The Bruce is a very trustworthy Potato, and I expect it to be, as usual, of excellent quality when the time comes for using it, but I have never seen any difference between it and Magnum Bonum since the first year I grew it, and probably the extra crop it then gave may be accounted for by the seed coming on to new soil. Of Magnum Bonum

I got a fresh stock from heavy soil this year and the results have warranted the change of seed, for the crop is much heavier than is usual with this popular variety here. Although Potatoes are universally grown throughout the country and on greatly varying soils, there can be no doubt that they are much affected by the nature of the soil on which they grow. In judging allotments this year I have visited some parts of this country where the top-growth made by the Potatoes has been very meagre, only reaching a few inches high, and before the middle of July much of it had turned yellow or withered; still it was surprising to see the heavy crop, out of all ordinary proportion to the top-growth which had already formed and ripened on some varieties, while others, popular and good in other districts, were very inferior. I find that certain varieties suit certain soils, so that it is wisest in dealing with Potatoes not to be guided too much by hearsay, but to experiment for oneself. J. C. TALLACK.

Greenwich Park, Burg St. Edmunds.

Potato Syon House Prolific.—I had a good breadth of the above variety of Potato planted to ascertain whether it would again prove as satisfactory as it did last year. The tops having ripened off, the crop was lifted lately, and I am pleased to say that as regards quantity and quality the results are very satisfactory. I have not tested the cooking qualities, but, judging by the clean, sound look of the tubers, they will be all right in this respect. Last winter I considered it one of the best cooking Potatoes I had, so excellent was the flavour. It is without doubt a great acquisition for private gardens, and the result of this season's trial will induce me to grow it more largely still another year.—A. W.

White Artichokes diseased.—Touching the short note on Jerusalem Artichoke disease which appeared in THE GARDEN of September 17, can you offer any suggestion for destroying the fungoid germs which doubtless remain in the soil during the winter? Will soot, or lime from gasworks, or any other substance dug into the ground be likely to get rid of the disease?—W. K.

* * * Seeing that the stems at about 1 foot from the ground are the first part of the plant attacked, I do not think that any such things as "W. K." suggests for digging into the ground will be likely to stamp out the disease, though they might destroy some of the resting germs. Careful attention to rooting up and burning all plants attacked before the spores ripen appear to be the only practical method, and in doing this do not forget to examine any Sunflowers, annual or perennial, that may be growing in the garden. I believe that the first attack here began on some annual Sunflowers some years ago, but as only a plant or two was attacked here and there, very little notice was taken of it until it attacked the white Jerusalem Artichoke, which seems particularly susceptible to it. I have just pulled up and destroyed a dozen or more plants recently affected.—J. C. TALLACK.

Harvesting Onions.—But little time and labour have had to be expended on the harvesting of spring-sown Onions this year. So thoroughly have they ripened in both tops and bulbs, that all that has been necessary was to let them lie on the ground a day or so, when they are ready for storing. So firm and well ripened are the bulbs, that not the slightest difficulty should therefore be experienced in keeping them through the coming winter months. The tops have ripened off so close to the crown, that it will be impossible to tie them in bunches and suspend them on ropes this season, a plan I usually pursue. They will have to be spread out three or four thick instead, and this I shall be enabled to do in a disused fruit room, the shelves in which come in admirably for that purpose. All the same, I think they keep longer when suspended under the roof of a shed, so long as frost cannot damage

them, as a current of cool air is then continually passing freely amongst them. I do not grow any of the extra long growing varieties, and this year have confined myself to Maincrop, Bedfordshire Champion, Veitch's Globe, and James's Keeping. Having to produce a large quantity every year, I find these the best for spring growing, and in my opinion no better Onions can be grown where a long and continuous supply has to be kept up.—A. W.

THE POTATO CROP OF 1898.

This has not by any means been the most favourable season in this part for the production of fine tubers or heavy crops, although where the soil was in good condition fair samples have been grown and the tubers of excellent quality. Here we suffer much from late spring frosts, so that it is necessary to be careful not to plant too early, and although every precaution is taken to guard against being caught, it sometimes happens that after a spell of bright sunshine we have cold, frosty nights, such as that experienced here on the morning of May 13, when the thermometer fell to 25°, or 7° of frost. There were several slight ones after this date, but as the growth of the Potatoes had been cut down to the ground by the former frost, it had not started again. It is a fact that when once the haulm has been injured the tubers are never so large, therefore the crop cannot be so heavy, and as it is impossible to grow the same weight from late-planted sets unless the seasons are exceptionally favourable, it is an inducement to run the risk of having the haulm cut down. Here no planting was done until April 13, but as the winter had been so mild the growth on the sets was unusually forward; hence the reason that it so soon appeared through the soil. Of the sixty or so varieties that were grown here, it was interesting to watch their growth and note the difference both in crop and quality of tubers. If we take the different sections, such as round, pebble, and kidneys, and divide these into early, medium, and late, there is doubtless something to learn both as regards planting, soil, and space allotted to each. It has for some years been an important point with me to test each variety thoroughly before passing an opinion upon it, but it is not always possible to do so in one season, as there are various things to be taken into consideration in so doing. For example, when a new variety is sent for trial, it is seldom that any idea is given of its habit, whether robust or otherwise, and as this cannot be ascertained for some time, when several strange varieties are planted side by side some are sure to suffer, as the weaker ones will become overgrown by those requiring more room. Last season I was much struck with a variety sent me for trial under the name of Ideal. The haulm is of medium growth, tubers of even size and excellent quality. This being a midseason kidney variety will no doubt become very popular. From two rows 20 yards each in length the produce was two sacks, or a little over 17 tons per acre. There was not a diseased tuber in the whole lot. Invincible is another first-class new variety. The tubers are kidney-shaped, skin rough, flesh white. The haulm is of medium strength, inclined, if anything, to be robust. The crop was all that could be desired, as the produce was at the rate of 24 tons per acre. Of the round mid-season and late varieties, the most productive was Snowball. Two rows of this were also planted, and the crop was such that those who saw it were much astonished. The tubers are a flattish round, even in size, good in shape, having very shallow eyes, and

the quality is all that can be desired. The produce was at the rate of 26 tons per acre. This variety is rather a strong grower, and should therefore be planted at least 3 feet apart where the soil is in a high state of cultivation. Monarch is a splendid white round variety. The tubers are even in size, perfect in shape, good in quality, and it is an excellent cropper. The haulm does not grow quite so strong as that of Snowball, but the tubers resemble them somewhat in appearance. Goldfinder is a handsome white flattish round variety, even in shape and good in quality. The haulm is not very robust, therefore well suited for growing in a garden. With me the crop was all that could be desired. In Progress the haulm was too strong on our heavy soil, spreading over some of the others next to it. There are, however, some very handsome tubers, but the crop was not a heavy one. Motor also grew too strong, though the crop was fair and the tubers sound. Industry produced a fair crop, but the haulm grew too strong. Duke of York is a beautiful white kidney-shaped variety, and will no doubt come to the fore as an exhibition kind. Syon House Prolific has done wonderfully well this season, the tubers being large, even in size, and well flavoured.

It is some time since I had so few diseased tubers; in fact there were not more than a dozen in the whole, and so clean are the skins of the tubers that one would think they had been grown in the finest Potato soil possible. Some of the late kinds have suffered from the long-continued dry weather, the tubers not being so large as in former years.

Buxton Park, Uckfield. H. C. PRINSEP.

CLUB IN CABBAGES.

ENCLOSED are specimens of Cabbage and Cauliflower that have clubbed, and I shall feel grateful to you for any information as to how it is caused and what I can do to prevent the same in future. Out of about a thousand plants not one is free from this scourge. My spring-sown plants nearly all went the same way after they were planted out and had got to be a good size.—A. K.

** The specimens sent were very bad indeed, and to eradicate the same strong measures are necessary. The cause of clubbing is the Cabbage fly (*Anthomyia brassicae*), the maggots of which when full grown leave the plants and turn to pupae, inside which the flies form. These flies are of an ashy grey colour. The remedy often advised is of little use to growing plants, the pests being in the earth. The best way is to rid the soil for future crops. I have watered with a solution of petroleum with partial success, and also with carbolic acid mixed with soap-suds. The plants are free for a time, but it is only a partial remedy and useless with plants badly attacked. The only remedy is to destroy the plants and prevent the pest reappearing by dressing the soil. The evil is aggravated by planting year after year Brassicas in the same place. Other plants, such as Onions and Spinach, should not occupy the land for a time. The soil would be benefited by resting, a thorough stirring in winter, and growing a green crop that could be dug in. For years I have had land to deal with that will not grow two crops of any kind of Brassica without clubbing. In a limited space one must at times plant a similar crop, and it can be done if strong measures are taken to rid the soil of the pest. There is no better time than the present. For some years I have found that land in a bad state was not the best position, even after dressing, for the Brassicas, as there is always a tendency to club even with small plants. I find it a good plan to plant such land with early Potatoes. These are cleared early, and the soil can be again dressed, and is sweetened by the time it must be cropped in the early spring. The best remedy is

gas-lime, which I use liberally on the land before cropping, and in your case it may be given freely. A good dressing of fresh gas-lime spread over the surface for a few days and then dug in will be of great assistance in destroying the pest. It is well to break up the lime as small as possible, and if the land is double-dug or trenched, give a small dressing under the second spit and let the soil be as rough as possible after trenching. Soot also is a grand fertiliser. Omit animal manures for a season, using instead guano, superphosphate of lime, or nitrate of soda, which may be given in the early spring in wet weather. It is a good plan to occasionally fork the surface over before cropping. Ordinary lime, burnt refuse, and wood ashes mixed and placed in the rows before planting will keep the plants clean for a season. I always use a little fine gas-lime before cropping with any kind of Brassica.—G. W.

GARDEN FLORA.

PLATE 1192.

CINERARIA STELLATA.

(WITH A COLOURED PLATE.*)

To those who have partially tired of the perfection of form (so-called) of the florists' type of Cineraria has been afforded no small amount of pleasure in the introduction of the star-like varieties. The florist no doubt who adheres rigidly to the rotund form of blossom with its almost mathematical shape will not view with any special interest this more recent introduction, but look upon it with disfavour. Without for one moment attempting to detract from the merits of the florists' type as now grown, it must be stated that this new development of the Cineraria has very much to recommend it. To many it will come as a welcome relief, affording fresh variety to a charming class of spring-flowering subjects. As conservatory plants they are specially to be recommended, being more easily associated with other and taller subjects than the florists' Cineraria. They would be fitting companions to the early-flowering white Marguerites. Already there is a pleasing variety of colour, no less than six forms being represented in the accompanying plate. Upon observation it will be readily acquiesced in by many readers of THE GARDEN that the self-coloured varieties are much to be preferred to the bi-coloured variety, white, tipped with rosy pink. The self colours when of decided tints are much more effective. In a cut state these Star Cinerarias have much in their favour, being better for arranging in many ways than the others are by reason of the length of stem obtainable; whereas from point of effect also an advantage is gained by the less density of the corymbose heads of flowers. It is to be hoped that the florist will not attempt to "improve" this more recent introduction in either the size or the form of the individual flowers. If he can reduce the size of the leaf it would be an advantage, and we would thank him for it. The cultivation needed is nearly the same as for the usual run of Cinerarias. Whilst shade to a certain extent is beneficial, too much will be harmful. Overpotting, again, should be guarded against, also overcrowding.—SOUTHRON.

Messrs. Sutton and Sons send us the following notes *re* the varieties of Cineraria stellata figured to-day:—

This pretty race of Cineraria is the result of crossing several varieties of the florists' Cineraria with *C. cruenta* and *C. multiflora*. It is not the

* Drawn for THE GARDEN by H. G. Moon in Messrs. Sutton's nursery at Reading. Lithographed and printed by J. L. Gouart.

result of one plant selected from either of these crosses, but the intercrossing of a number of distinct forms resulting from the original crosses, all of which varieties were selected on account of similarity in habit and flowers. The special points which have been aimed at in selection for seed have been freeness of flowering, small stellate flowers, and white, bright pink, and blue flowers in contrast to the magenta shades which were so abundant in the result of the first crosses. The exceptional value of these plants is not so much for the greenhouse as for standing in groups on the floor of the conservatory or dwelling-house; also for their great usefulness for cutting for the table. The larger sprays in large vases, with abundance of Maiden-hair Fern, make a most beautiful decoration. This *Cineraria* has great merit in the length of time the flowers remain fresh after they have been cut, also the ease with which they travel, probably owing to the stem and branches being more woody than in the large-flowered greenhouse *Cineraria*. It has an exquisite perfume, which has been compared to that of the Hawthorn or *Heliotrope*.

The culture of *C. stellata* is of the simplest description. A compost of three parts of loam to one part of leaf soil, with a sprinkling of coarse sand, will give the best results. As the pots become filled with roots frequent applications of liquid manure may be given. Temperature, watering, and fumigating must be carefully attended to, as in the case of the large-flowered types.

THE WEEK'S WORK.

HARDY FRUIT GARDEN.

ROOT-PRUNING.—Where there is any need of this being done, it will not be advisable to postpone the work any longer. Even if the growth be backward, with the foliage still immature, that should not be any reason for delay. This very fact may have a tendency in the right direction, and far more so than any excessive top-pruning will do. In some instances it will not, perhaps, be advisable to do the operation completely in one season, as, for instance, in the case of somewhat large trees, which ought to have been attended to a few years earlier. These should only be half done or a trifle more so, finishing the work in twelve months' time. Regulate the distance from the stem to that at which the roots are to be severed by the size of the tree in question. It will be a good rule to add one third in length to what would be allowed were the trees to be completely lifted, for it is not an undue amount of checking which should be the aim. If a tree be cut about half or slightly more around, it will be possible to incline it so as to get at the most important roots, viz., those with a downward tendency. It is these which will need most attention. Let the cuts be made as clean as when pruning the top branches with the wound downwards and never upwards, so that the young roots as they are emitted may trend in the right direction. Do not attempt to do much pruning to the medium or fibrous roots, but rather leave these as much undisturbed as possible, this being another reason for keeping further away from the stem than in lifting. Leave some indication to each tree as to the portion operated upon; this will save trouble another season. When the soil has all been carefully replaced, no manure being used with it, let the trees be well watered so as to settle it down at once, and in the case of top-heavy ones some security must be afforded in windy positions. Muleching the trees upon the surface is advisable in all light soils. This will not have any material tendency in fostering another rank growth. When wall trees are to be operated upon, look to that side of the tree first which has the stronger growth; if there be any difference. Another good plan with these is to go direct for the centre of the tree under the main stem, leaving, if need be, the sides nearer to the wall undisturbed.

When dealing with Peaches, Nectarines, Apricots, or, in fact, any tree where the tendency is to make downward roots or feeders of gross growth, it will be found a good plan to push two or three good-sized roofing slates under the centre, so as to prevent this being done again as far as possible. If Apricots are giving trouble by making too much growth it will be as well to cut the roots off the whole length of the borders at about 3 feet or so from the wall. This if done annually will tend towards the fruitfulness of the trees. The same remark would apply with equal force to Cherries in luxuriant growth, to prune which at the branches and not at the roots at all is simply absurd. Do not, on the other hand, be too severe upon them. It will not be necessary in the majority of cases to add any fresh loam even for wall trees, but a little bone-meal may with advantage be added for all stone fruits upon non calcareous soils.

LIFTING AND RE-ARRANGING TREES WHERE OVERCROWDED.—This work also should receive early attention, thinking the matter out well beforehand so as to make the most of the labour at the time, having fresh positions selected to suit the circumstances of each case. Trees are often planted more thickly than it was ever intended they should remain, but for some reason or other the work of removal is deferred till it may, perhaps, have been given up altogether. In many instances it is most desirable to allow for extension of growth in this way. It is infinitely better to do this than to restrict the growths by any undue limitation of pruning. Some of the finest examples of wall fruit culture are to be noted where the extension of promising trees has been adopted. No regular distance from tree to tree can ever be entirely relied upon, for in scarcely any two instances will the growths be of similar vigour. It is better to have large trees, still thriving and extending, so far apart as to allow of cordons for the time being between them. When removing large trees, take every possible pains with the work, adding both fresh loam and manure to fruitful trees. Do not let temporary crops upon the borders stand in the way of doing this work in a systematic manner. So far the weather is quite favourable for getting this work forward; it is better done now than after heavy rains, assuming, of course, that the trees have been kept watered sufficiently to prevent the soil from becoming excessively dry. Do not hesitate to do away with any tree that is in an unhealthy or otherwise unprofitable condition. Overcrowding will at times result in this. As I am writing these lines a case occurs to me of a fine wall which was excessively overcrowded, and upon which many words of praise were expended for the rapid filling up and the fine appearance of the trees at the time. Years have elapsed, and on no one occasion do I remember to have seen a good crop throughout its length. Now the trees are doing their best to kill each other from want of space. Exhaustion at the roots in such an instance is only a foregone conclusion. When removing large-sized trees do not hesitate to syringe them afterwards, or even shade with mats for a time if necessary.

PREPARING FOR NEW TREES FROM THE NURSERY.—Let this work be proceeded with without any delay. I will assume that previous hints have been taken and that the requisite numbers have been marked, or at least ordered, for early delivery after rains. Avoid, if possible, the planting of any one kind of fruit tree after another of its kind. If this cannot be done, then remove a good proportion of the soil, adding fresh loam if possible, but if not, then take it from the open quarters under vegetable culture. Note the requirements in every case as regards any manurial addition. As a rule the addition of nitrogenous manures is a mistake. Only in the poorest of soils or those of a very light character would I recommend it. To encourage luxuriant growth in young trees is altogether a mistake. Mulch with farmyard manure in every case certainly, but do not incorporate it with the soil, bearing in mind that a moderate growth is more

desirable than a rank one. Add for stone fruits such as old mortar rubbish, bone-meal, or artificial manures in a moderate degree. These will afford the best plant foods for fruit trees. The holes for such trees as are thus being added should be got ready before the trees arrive if possible, so that no laying in by the heels or after exposure of the roots is permitted. In doing this move the soil to a good depth and bring up a lower spit if it be of the right kind (neither gravel in shallow soils nor clay in deep heavy ones can thus be brought up with advantage). If several trees in a stretch are to be taken out, it will be possible to thoroughly move the soil and treat it for the new ones in a better fashion. During planting do not forget to add the slates afore alluded to if by experience already gained a strong growth is anticipated; nor the watering-al-o, which is always an important matter. In planting new trees, be careful not to plant any deeper than they were before; each one will sufficiently indicate this. Do not attempt any nailing or tying of wall trees in a permanent manner, nor, on the other hand, let them touch the wires if these be galvanised. Both Peaches and Nectarines will invariably suffer if the wood of the current year touches the wires in such instances. On the other hand, secure by means of stakes all trees in the open quarters, and bush fruits also if large and in windy positions.

PLANTING FRESH TREES INSIDE.—This has not been directly alluded to, but in most instances the foregoing remarks will apply. An important item, however, is the drainage, without which the amount of water that will of necessity be given the growth will be too excessive in the case of Peaches and Nectarines. Here, again, some slates will be useful if concrete be not used. Upon heavy or retentive soils it will pay to concrete the bottoms of the borders at the start; it will then be known where the roots are, being thus easily under control. Select as good loam as possible for inside borders, but note previous remarks as regards manures in addition thereto.

HORTUS.

KITCHEN GARDEN.

GENERAL WORK.—Under this heading there is a lot of work needing almost daily attention. At this season the quarters, unless kept neat, will present an untidy appearance, and a free use of the Dutch hoe will do much to keep down weed growth. So far there has in most parts of the country been but little rainfall, and though the soil has dried less, owing to the fall in the temperature, such plants as Celery, salads, and most kinds of Brassicas need rain badly, while newly-planted things will need watering to keep them going freely. I fear in the southern parts of the country there will be none too good a supply of vegetables for the early winter. The best plants this season are those grown in land not newly dug. In my case most of the Kales and late Broccoli followed Strawberries, and these have done much better than plants in loose soil—I mean such as in early Potato quarters. With a scarcity of green vegetables it will be well to pay more attention to the spring Cabbage and early Cauliflower planting. Much may be done even at this late period to eke out the supply of the vegetables that will soon be cut down by frost. I have kept dwarf Beans for weeks by covering at night with mats supported by rough boards. Marrows will also keep for weeks if put into a cool place, the stalk end being in a couple of inches of water, with a little charcoal in the water to keep it sweet. There will be no difficulty in protecting the runner Beans, such as Tender and True. This season this type of Bean has been most serviceable, as it holds out better than the dwarf section, which has been a difficult matter to keep free of red spider. This new class of Bean also needs less attention than the Scarlet Runner. Land cleared of crops should be made neat. I am busy wheeling out manure and lime to quarters cleared of crops, as the surface being in a dry state it makes the work easier. In my case I can cart the materials to the spot desired, having

broad walks. Such crops as Brussels Sprouts planted early will be benefited by having the lower leaves removed. They are turning in much earlier than usual. In many places it may be necessary to use the sprouts, but this should, if possible, be delayed, as I note they are somewhat strongly flavoured. They need more moisture, frost also to sweeten the crop. Rhubarb will soon be needed for forcing, and where the Apple crop is poor this will be found useful. The larger portion of the leaves may now be removed to admit air and moisture more freely to the roots and swell up the crowns. Seakale will, with autumn rains, make a later growth, and if needed for early forcing should have a goodly portion of the old leafage removed. A few roots may be lifted if very early supplies are needed. Those placed under a north wall for a short time and covered with leaves or mats will force more readily than roots lifted direct and placed in heat. When the root crops, such as Potatoes, have been lifted, it may not be convenient at once to dig the land; indeed, in my case it is much too dry. It may be hoed and raked over to clear weeds and rubbish and present a neat appearance. The walks will now repay for more attention in the way of sweeping and rolling. I notice edgings of Box are making much later growth than usual. This should be lightly cut if portions have grown more in some parts than others.

SPRING CABBAGE.—I have this season had more trouble with the July sown Cabbage than ever I remember. The seed in the first place germinated badly, and there was a difficulty in keeping birds from the tender seedlings, while the heat and drought caused so many plants to go blind, that I fear in many gardens plants are scarce. This is more annoying in such seasons as this as the winter green crop will be scarce, it being impossible to plant owing to drought and heat. To make up for lost time it will be well to make later plantings. I advised sowing later in case of the earliest lot being too large. These later plants will now be small, but they will soon go away if we can only get some rain. The earlier-planted lots do not look any too well, and will, I fear, not be reliable. For this reason it may be advisable to make a larger planting of the second or later sowing, and any small seedlings left over will prove serviceable for February or March planting. If these are pricked out in rows a few inches apart they will make a better growth than if left in the seed bed. It is well to make the soil firm if at all light previous to planting. Coleworts grown for latest supplies will be valuable this season. These made little growth earlier in the season, and now will well repay for supplies of food in the way of liquid manure or a fertiliser given in rainy weather.

LATE DWARF BEANS.—Some few weeks ago I advised sowing these for the latest supply. I fear in many gardens, unless ample supplies of moisture have been given, the plants will not be so good as usual. On the other hand, if at all strong there will be a fair return, as the season so far has favoured setting. It will be necessary to protect the plants. Any kind of protection that will ward off night frost will suffice. If frames or glazed sashes can be spared, so much the better. I use thatched hurdles, which can be readily placed in position at night and are most effective protectors, as after the Bean crop is cleared they come in for the late Cauliflower or early Broccoli when lifted and placed close together. With late Beans the most important detail is to admit ample light to the plants, as the pods swell more slowly at this season. By removing old leaf-growth and keeping clean the pods will grow till the end of this month. It will be well to give the plants assistance in the way of moisture and food, and to water so that the plant is dry by nightfall. In mild autumns I have had good pods well into November from late sowings.

WINTER SPINACH.—Like most of the shallow rooting crops, the plants sown in July or early August are not so good as usual, owing to the drought. On the other hand, in northern locali-

ties there has been a heavy rainfall. I would advise thinning at this season, as a thick plant is the first to feel the effects of frost, and winter Spinach should be grown as hardy as possible. More crops are lost by thick sowing and leaving the seedlings too thick. Plants suffering from drought will well repay liberal supplies of moisture. Previous to watering it is well to give a dressing of soot to assist growth and at the same time give that healthy green colour so much liked. If liquid manure can be spared, Spinach will take it freely. I find it best to give it diluted if at all strong. Far better give it often than in a fresh state. Late-sown plants should be thinned as soon as they are large enough to handle, and also given a dressing of soot to ward off slugs, which have a weakness for the young seedlings. These late-sown plants will give a good supply next spring, when the earlier sown are running to seed and before the spring-sown is ready.

CELERY. no matter whether early or late, with me and many others is, I regret to note, so badly infested with the fly or grub, that it is impossible to keep it down, whatever precautions have been taken. My hope now is that by the middle of the month the climatic changes must be in favour of a cleaner growth. Want of moisture is the cause of the pest having made such headway. Soot dressings and hand-picking are the usual remedies, but one can only go so far with the latter. I recently saw plants without a leaf, but this is worse than the fly, as in such a condition the plants will fail to grow. It will be well to leave any plants so affected as long as possible without moulding up. If the plants are well fed, clean leafage will soon be made. I have found a weak solution of soluble petroleum given at night do more good than soot dressings. The pest is in a measure proof against dressings of any kind, but I notice it does not spread to the foliage that has been well covered with the mixture advised.

LATE CELERY.—The plants should get liberal supplies of water at the roots previous to earthing up. In my case the soil is so dry that much rain will be required before it would reach the roots. Now is a good time to give a final watering before moulding up, and a little salt will add to the flavour. This is best given before water is applied, as then it reaches the roots more readily. All plants, either late or early, previous to being earthed up will have made some small leafage, which is now best removed. At the same time side shoots should be pulled away. If the roots are at all dry, which is often the case, it is a good plan to flood the rows a few hours before moulding up. Much better results will follow if the latest plants are not moulded up till very late. Liberal supplies of food may still be given, but avoid liquid manure in a crude state. This is not good at any time, especially at this season of the year. A little soil may be given the plants fortnightly, but leave the final earthing up as long as the weather is open. S. M.

BOOKS.

THE FRENCH HORTICULTURAL SOCIETY OF LONDON.*

It is always pleasing to watch the growth and expansion of a well-managed society, be it specially concerned with horticulture or not. The French Horticultural Society of London has every reason to be proud of its position, for although only established nine years ago, and never having the attractions of a show at its command, it musters, according to the annual report, 424 members, many of whom are well known in their several departments and comprise residents in all parts of the globe.

The society's annual publication now under notice is certainly as interesting and as well produced as any of its predecessors, and the matter leaves little or nothing to be desired. It is, of

* "Bulletin de la Société Française d'Horticulture de Londres." (20, Bedford Street, Strand, W.C.)

course, chiefly intended for members, but much that it contains will commend itself to others than those on the muster roll of the society. Leaving out with just the briefest mention the lists of officers, members, rules, library accessions and the like, we find that the Bulletin contains concise reports of each monthly meeting held during the past year together with a special account of the annual dinner held in January, a most enjoyable and successful gathering and one fast increasing in popularity.

The purely literary portion of this publication consists of a series of papers by the members on such subjects as Anthuriums, Pelargoniums, Lilies, Adiantums, Fuchsias, Bouvardias, Orchids at Kew, Caladiums, &c., some of which indicate considerable pains being taken by the young authors, one of the most notable being the article on the National Chrysanthemum Society's Exhibitions of 1897. Some of the articles are illustrated and an excellent portrait of Mr. Harman-Payne forms the frontispiece, accompanied by a notice from the pen of Mr. Geo. Schneider, the worthy president of the society, whose efforts in improving the relations between English and continental gardeners are worthy of the highest commendation.

ORCHARD AND FRUIT GARDEN.

PLUMS IN 1898.

GENERALLY speaking, Plums may be said to have been a variable crop. In some gardens and districts there were heavy crops, in others a scarcity. On the whole, Plums in these gardens have been very good. Some trees were so heavily laden that severe thinning had to be resorted to in a green state, and in the case of Victoria and Pond's Seedling, early gathering for daily consumption was necessary when ripening to allow the fruits to attain a normal size. These are fine cooking and preserving sorts, and are prized more than all others for these purposes. When of large size and nicely ripened, Pond's Seedling is inquired for here as dessert, although it is not usually considered as such. It is a long time since Plums were so late in ripening as this year. In early August none but Early Rivers was available for any purpose. Washington, Orleans, and Oullin's Gage, sorts I can usually gather in the early part of the month, were then almost green, and at any rate quite hard. Washington was in use at the end instead of the first week of August. Jefferson's, another very useful midseason sort, I can usually gather in quantity about the middle of the month; this season I could not gather enough for one dish on the last day, although trees occupy east, west, and south walls. Much the same remarks apply to Kirke's, a dark Plum of similar quality to the last named. Gages of all kinds have been abundant, and, taking the nature of the season and the weight of the crop into account, they have been very fine. This proves that the roots of the trees are sufficiently deep to escape the much-prolonged drought, an advantage certainly in such seasons as the present one has been. Trees whose roots are near the surface suffer considerable loss of vitality in cases where no water is available for them. A mulching checks rapid evaporation and wards off, to some extent, the great heat from the sun, but it affords but poor relief to languishing trees. Trees in this latter condition cannot lay up or provide for next year's crop to much advantage: flowers must of necessity be undersized and weakly. Coe's Golden Drop, one of the finest of autumn Plums, is at the end of September only available to a small extent, although several trees occupy spaces on west walls. Each tree, however, carries a fair quantity, so that the

supply will last well into October, if not until the end of the month. This Plum ought to find a place in every garden where wall space can be found, preferably on an east or west aspect. It possesses such fine substance that it does not soon decay after it has ripened like most summer Plums and Gages. Sometimes it can be saved until the middle of November when wrapped carefully in tissue paper and stored in a uniformly cool and dry place. I have not been successful in continuing even a small supply so late as that date, but probably this was from want of the ideal store in which to keep them. One thing is assured, that when such delicious Plums can be produced in November they are appreciated, because then fruit is limited in point of variety. Prince Englebert and Grand Duke, two black Plums, more suitable for cooking than dessert, are sure bearers and most useful. This year they each carried a full crop and continued a supply successively throughout the month of September. Coe's Late Red has a lighter crop than usual; Blue Impératrice bears a greater quantity. These latter sorts, though small, are most desirable for late autumn, coming into use, as they do, when main crops are over. Monarch, of which I have but one tree, is this year without a crop.

Few fruit growers will readily forget the bitterly cold and boisterous winds experienced in March, damaging, as they did, so much early fruit blossom. Some trees here being fully in bloom had a double thickness of fish-netting fixed over them for shelter, but at the time it did not appear probable even that they would derive any benefit because of the high and searching nature of the frosty winds. Many, if not the greater portion, of the early blossoms were undoubtedly destroyed; those opening later from the base of the spurs escaped in sufficient quantity to produce a crop. On some of these early trees the fruits are more undersized than usual, attributable no doubt to the loss of the strongest and best placed blossoms.

Aphides have given a deal of trouble, and would have been more so but for the early attack on them with an insecticide. Where they have been left unattended the trees and crops have suffered badly, and the ill-effects will be carried into next season. Crippled leaves and consequent exhaustion of the trees carry unpleasant anticipations of a more or less uncertain character. If a soaking of manure water or a dressing of artificial manure of some approved kind were given and well carried down to the roots by rain, much help would be afforded. Where aphides, too, are troublesome, a well-applied dressing of petroleum emulsion would not be without good results, as it would destroy many insects lurking about the trees and in crevices of the walls. In very bad cases it would be well to paint the trees—old ones in particular—with a mixture containing a strong insecticide, removing the surface-soil from the base of the wall, and replacing it with fresh from the open quarters and well away from fruit trees. There are great destroying powers in hot water as applied to insects on trees. Applied with the syringe as hot as the hand can bear it, many tender-coated insect pests can be destroyed, but this remedy is only admissible after or about the time of the leaf-fall in autumn. W. S.

Road Ashton, Wilts.

Keeping Walnuts.—At p. 272 "J. G. W." asks as to the best way of keeping Walnuts. After trying many methods, I cannot find one to equal keeping them in clean sand. I put the Walnuts into big flower-pots in layers, covering each layer

with clean coarse sand. I use silver sand, although any rough sand will do just as well. When finished, the pots are placed on a damp brick floor in the fruit room. Boxes or pans of any kind would do just as well, although I prefer earthenware vessels. When these are wanted for use I brush them with a stiff brush to remove the sand. In this way I have had Walnuts good up to March. I have adopted this plan during the last ten years. The best way I can keep Filberts or Cob Nuts is to put them into a dry box and place them without anything amongst them in the same position as the Walnuts.—DORSET.

Ripened wood.—I fully agree with "H. R." (p. 195) that we may have too well-ripened wood, I have seen young Vines fail badly because of the wood being so hard and dry owing to premature ripening, that the Vines, though strong, would not break, the crop being poor in consequence. Much depends also how near the roots are to the glass, and if at all close, far better shade slightly than lose the large leaves, which have so important a part to play in the swelling up of the buds. Three years ago I had two houses of young Vines. One lot was ripened off much earlier than the other, being needed for early forcing. The crop was very poor. The Vines allowed to make later growth and not stopped so hard were all I could wish. There is no gain in roasting the wood. The growth of the plant is checked. Over-ripened wood does not facilitate forcing. One cannot force soft wood, but there is the happy medium "H. R." so well describes.—W.

Ripening pot Vines.—I never had pot Vines looking so well as those which have been grown without bottom-heat and allowed to make a liberal top-growth. It will be well to now reduce the side growths and cut back hard to the first lateral growth. There can now be no question as to the ripeness of the wood. The Vines will now benefit by exposure, but it is well to see that the roots get ample supplies of moisture. I have not moved my Vines of late years, as often when placed in the open the winds twist the canes about and the roots suffer if the pots are exposed. The sashes on the pits are taken away and the rods syringed freely, and they ripen up grandly. When we get frost the leaves soon fall. Many pot Vines bleed badly when shifted, this showing the necessity of cutting back the canes to the desired length and shortening the laterals so that the cut portion is well healed over. I always get this work done by the end of August. It is an easy matter to ripen up the canes and prune close to the main stem a little later.—G. W. S.

Blackberries.—With reference to Mr. Crawford's note, I have experimented with various kinds of Blackberries for several years, the result being that the only one worth growing is the Parsley-leaved variety (*Rubus laciniatus*). Plants of this which have been in their present position for five years have borne a large crop every year after the first. This year they average 5 lbs. each. In the same row, planted alternately, I have Wilson Junior, not one of which has ripened a single fruit. The ground is sandy, very dry and poor, and fit for nothing else. Wet or dry, cold or hot, the fruit is always good and well ripened; it is the only crop which never fails. The fruits average from twice to three times the weight of the best samples of the wild variety. Blackberries would be a paying crop where nothing else would grow. It must be borne in mind that such crops as I get can only be obtained by manuring. In favourable situations I have seen this variety growing on a wall covered with a solid mass of fruit, the canes being quite 18 feet high. My experience only is on the poorest ground, where I never expected it to fruit at all.—THOS. FLETCHER, *Grappenhall, Cheshire.*

Value of early Peaches in the south of France.—A dozen of the principal producers, writes M. Nardy Père in *Le Jardin*, of the Hyères region gather each from 3000 to 6000 kilos of the fruit (3 to 6 tons). One estate, which is one of the best managed in Provence and is known as La Décapris at Hyères, belonging to

M. Raymond Aurran, produces a crop of early American Peaches annually weighing between 50 and 60 tons. The last crop was much less; it only reached 10 tons of Amsden June and Alexander and 1 tons of Hale's Early. A quite abnormal occurrence of frost on March 25 and 26 destroyed three-fourths of the crop. In the same region of Hyères another estate known as the Oratoire, belonging to the Marquis de Larenty, and comprising alluvial lands in the very rich valley of the river Le Capeau, competes with La Décapris in the quantity of early American Peaches grown and exported. The last crop at the Oratoire, which, happily, escaped the frost of March 25 and 26, amounted in Amsden June and Alexander to 35 tons, and in Hale's Early to 15 tons. We certainly do not exaggerate in calculating as 200, and possibly 250, tons the total quantity of early American Peaches put upon the railways of the last gathering.

Bees and fruit.—In THE GARDEN (p. 261) under the heading "Destroyers," Mr. E. Burrell makes the following, to me astounding, statement: "So far as the softer fruits are concerned, bees at this season of the year are quite as destructive as wasps." I have little doubt that on his attention being called to the matter he will admit that he has unwittingly exaggerated; but as one who for many years has taken an equal pleasure in bee-keeping and gardening, I am anxious to ascertain whether even a softer impeachment can be fairly made against my favourites. It is quite possible that bees deprived by a greedy or ignorant owner of the stores they had laid up for the winter may under the pressure attack fruit sufficiently sugary, such as Grapes, especially if there should be no neighbouring hive to rifle. I am not concerned to defend their morality. Personally, however, I have never once seen a bee attacking any fruit, and my gardener, just questioned, tells the same tale. It should not be forgotten that several British bees somewhat closely resemble the honey-bee, while "at this season of the year" an insect commonly known as the drone-fly is abroad in great numbers, and this is constantly mistaken for honey-bees, as in company with them it is seen sporting about the blossoms of Michaelmas Daisies and other autumnal plants. For this reason the evidence of those thoroughly familiar with hive bees would be most valuable, but I shall be grateful to your readers for any definite information, favourable or otherwise. Should their experience happen to be adverse, I beg that they will kindly mention whether they have often witnessed the offence or whether the instance quoted is exceptional.—H. J. O. WALKER, *Lexford, Buxleigh Salterton.*

WET AUTUMNS AND POT STRAW-BERRIES.

GARDENERS who have to produce ripe Strawberries in February or March are often disappointed after a wet autumn by their first early batches of plants going blind or failing to throw up trusses of sufficient strength. In many gardens, however, this might to a great extent be prevented by a little timely precaution. For instance, where there is a range of cold pits or frames the plants might be placed in them, say at the end of August, the lights being tilted over them during wet weather and entirely removed when fine. Of course, care will be needed never to let the plants suffer from want of water, as they will dry more quickly than those in the open air. If the frames are not wanted for other things, the plants may remain in them until taken indoors in November. There is no need thus to treat the later batches, as these, having a longer season of rest, are better prepared for the work when time for forcing arrives. Varieties which naturally produce many crowns are not so well suited for forcing as those which as a rule produce but one or two, although Vicomtesse Hérisart de Thury is an exception. Conspicuous amongst the first-named section are Royal Sovereign, La Grosse Sucrée, and the old Keens' Seed-

ling. Some gardeners make a practice of reducing the number of crowns to one on each plant when more are formed. It is well to bear in mind that the only guarantee for success in fruiting early Strawberries is layering early and giving the plants a position fully exposed to sun and air. Plants are sometimes stood by the sides of walks where pyramid Apple or Pear trees overshadow them, but in such a position they stand but a poor chance of early maturity. I knew one gardener—and it is a good plan where ground is plentiful—who always selected a plot from which Peas or Cauliflowers had been cleared, had it dusted with lime, and raked over. His pot Strawberries, as soon as severed from the parent plants, were set thereon four rows abreast, then a 2-foot alley. In due time every other plant was removed and more rows made. The position was one with a gentle slope to the south, where the plants reaped the benefit of every ray of sunshine. J. C.

Badly-shaped Apples.—Whatever may be the cropping qualities of an Apple, however fine it may look on the tree, and however attractive its general aspects, yet if it be of bad shape or entail much waste in the preparation for table, then is it less deserving of praise than are other varieties that are of better shape and more economical. I could not notice that the finer fruits of Bramley's Seedling shown at the Crystal Palace the more were they objectionable as cookers. That was also the opinion of one of our leading market growers. Another much-praised Apple which comes into the same category is Cox's Pomona. Both these have the stems deeply inserted in a large hollow cavity, and the eyes also are almost as deep.—A. D.

Plum Washington.—Many failures with this Plum are, I think, due to the trees having a too rich root-run. It is a strong grower, and if planted in a deep rich border is sure to disappoint, making rank growth year after year. It requires a poor soil, with abundance of old mortar rubble added, this being made firm, and a few slates or tiles placed beneath to keep strong roots from descending. Even then it may require root-pruning once or twice to induce fertility, but when once fruitful it is a grand Plum, delicious in tarts or made into jam, and when ripened on a west wall quite fit for dessert. Those whose locality permits of its being planted as a standard generally find that it takes some years for it to arrive at a profitable state.—Norwich.

Stone fruits at the Crystal Palace.—Probably the display of stone fruits at the Crystal Palace during the recent fruit show was never equalled so late in the season. Peaches, Plums and Nectarines were a grand show indeed, the lateness of the season making it possible to show very many varieties that in ordinary years are over by the middle of September. It may be considered strange that this should be so, as we have had months of almost unbroken sunshine and great heat during the daytime, but this has not made up for the coldness and dullness experienced over nearly as long a period in the early summer. The competition in all the classes for stone fruits was very keen, and many grand dishes had to be passed by without recognition by the judges. The analysis of the exhibits will be interesting reading, and may stand unique for many years to come.—J. C. T.

Late Nectarines.—The number of late varieties of Nectarines is not anything in like proportion to that of Peaches, still there are a few varieties which lengthen the supply, and these should be grown wherever this delicious fruit is esteemed. Taking them in their order of ripening, Spenser is a fine highly-coloured kind, being, when ripened under favourable conditions, of a beautiful mahogany colour. The flavour is rich and luscious, and the tree bears well. It is a great favourite with exhibitors. Another deliciously flavoured late Nectarine is Victoria, but this variety requires careful cultivation, as the fruit is liable to crack. A good light position and a

warm, well-drained border are the conditions necessary to ensure success. It is advisable to give these the protection of a cool house, although in the warmer counties the two first-named may ripen on an open wall.—J. C., Norwich.

PEAR BEURRE CLAIRGEAU.

THIS Pear is not nearly so much grown as it deserves to be. It is a special market favourite, a large, handsome fruit, and it rarely fails to crop: indeed, grown in bush form on the Quince stock it is very fine. On the Pear, in standard form, it gives a smaller return, but always saleable. This is a second-rate fruit as regards quality, but if gathered before it is quite ripe it is equal to some of less size and given a better name for quality alone. It comes in during October and should not be stored, but gathered and disposed of. It is finely

Pear Beurre Clairgeau.

coloured, and is not a coarse grower. It does well in light soils.

Grape Duke of Buccleuch.—I was very pleased to see from "E. M.'s" note (p. 234) that the Duke of Buccleuch Grapes at Gunton were fine again this year. Several years ago I saw the splendid bunches that were exhibited by Mr. Allan in competition for the prizes offered at Manchester by the late Mr. William Thomson, and could not help thinking what a pity it was this fine Grape could not be as well grown in every garden. The Vine at Gunton is not on its own roots, being worked, I think, on Alwick Seedling. I have found Golden Queen an excellent stock for the Duke. When at Coddington Hall I put a bottle graft on to Golden Queen, the result being that the young rod grew strongly, but not grossly, as it so often does when on its own roots, and produced bunches freely, these being of good, not sensational, size, the berries also colouring well and being quite free from the well known and ruinous spot. It is wonderful

how short a time it takes the Duke to ripen after the berries commence to soften.—J. C.

Peach Bellegarde.—In his notes on Princess of Wales Peach, "H" (p. 255) alludes to that excellent late variety Bellegarde as being a pale-coloured Peach, the fact being that it is one of the darkest Peaches in existence when grown well exposed to the light. "H" must either be growing another variety under this name or the conditions are unfavourable for colouring. Bellegarde was shown by many exhibitors at the fruit show recently held at the Crystal Palace, and in nearly every case the colour was quite dark. Bellegarde, as generally grown, is identical with the French Galande, and there is, or was, I believe, some years ago, a variety grown in France under the name of Bellegarde that was worthless in this country. This may possibly be the Peach grown by "H," though it is not very likely, as it was so little cared about when tried that it is not now catalogued by any of our fruit nurserymen. The true Bellegarde, as grown by me, takes on a deep

crimson-purple hue near the apex or on the exposed side, and is highly coloured almost all over except where it hugs the wall or is shaded in any way. It is certainly a grand late Peach, of hardy constitution, and a good grower. To dub it a pale variety is to rob it of one of its great attractions.—J. C. T.

Leaf-curl in Peaches.—There was nothing, says P. C. Reynolds in the *Country Gentleman*, in the climatic condition of last winter to discourage Peach growers: the winter was unusually mild. Only on one or two nights in the early part of February did the mercury fall below zero, and then only about 2°, and every Peach grower was satisfied when winter departed that the fruit-buds were alive and sound. The fruit-buds were indeed all right, and gave promise of a large yield of fruit; but when the leaf-buds began to unfold in early May the temperature ruled low and the growth of the young leaves was slow. Whether that was the cause of what followed, or whether there were other causes, is unknown; but in the latter part of May the Peach leaf-curl fungus

(*Taphrina doformans*) began to develop, and soon covered most of the foliage. Some varieties were affected much worse than others. The early varieties, such as Alexander, Amsden, and Waterloo, almost entirely escaped and bore good crops, but those varieties are not largely grown for market because of their tendency to rot, and also because they are partially cling-tones. The Early Rivers, the best and most extensively grown of early varieties, was badly affected with the fungus. Mountain Rose was somewhat affected, but not badly. Among other varieties planted to some extent in this vicinity, Foster, Elberta, Crosby, Crawford's Late, Hill's Chili, Oldmixon Free, and Stump the World were badly affected. Generally nearly all the leaves were more or less covered with the fungus, causing them to thicken, curl, and change colour to a whitish green, and soon wither and drop from the trees. The young fruit, no longer having the leaves to prepare their food, also dropped. Dormant leaf-buds soon began to swell and unfold, and the trees were again clothed in green foliage. But there were no dormant fruit-buds to push forth, and the trees remained fruitless. Of all the varieties of Peaches grown in Monroe County, New York, Crawford's Early was most exempt from the fatal malady, and that is the great market Peach of a good portion of Western New York.

PLANTING FRUIT TREES FOR PROFIT.

THE present-day planter of fruit trees for profit has far greater advantages, so far as varieties are concerned, than those who planted thirty years ago. The prolific character of many of the newer sorts of Apples and Plums enables the grower to realise heavier profits than were possible previous to their introduction to the public, to say nothing of the much shorter time in which many of them arrive at maturity. Those who contemplate forming new plantations for profit should be careful to make the best selection. Taking Plums first, a few sorts, such as Victoria, Pond's Seedling, and White Magnum Bonum, are equal to any of the more recently introduced varieties, but Magnum Bonum in standard form is only fit for the warmer counties. Black Diamond, though a fine Plum and pretty certain on a wall, is often disappointing as a standard, and though many plant it, it is only to find that after fickle springs the tree is minus fruit owing to the tenderness of the bloom. Rivers' Early Prolific is still indispensable for market, as it invariably carries a crop, and being when well ripened fit for dessert, always sells well. To follow it, Early Violet, a Plum comparatively little known out of the midlands, should be planted in quantity. In size and general appearance it much resembles Early Rivers, carrying a dense bloom and being delicious for tarts or for jam. Judging from the quantities of this Plum offered for sale in Norwich last August, I imagine that trees had been pretty freely planted in East Anglia. It is a prodigious cropper. Sultan, a large deep red Plum, something after the style of Prince of Wales, ripening at the end of August, is a first-rate market variety, a heavy and regular cropper, and of excellent flavour when cooked. Denniston's Superb, though small, must be included in the list, as quite small trees crop heavily and the flavour is equal to any of the Gages. It will hang a good while on the trees when ripe; colour greenish yellow. One of the best additions to market Plums is The Czar. I saw it fruiting well in a Norfolk orchard on quite young trees, the fruit hanging in clusters and standing wet weather without cracking. Pershore Yellow Egg, a medium-sized golden Plum grown by the acre in Worcestershire, is indispensable. It is an enormous cropper and of such fine colour for jam-making, that I am told large quantities of jam made of this Plum are sold for Apricot, a small percentage of Apricot being added. I think all market growers should plant a small breadth of Wydale. It will hang till November, and is then splendid for tarts or stewing. It is extremely hardy and a sure cropper.

As to Apples, unless a very speedy disposal can be effected, I think it is folly to plant many of the soft-fleshed early dessert kinds. The white Juneating, ripening at the end of July and keeping fairly well, is the best of this section. Of juicy and refreshing flavour and a certain bearer it always sells readily. The showy Lady Sudeley follows, and for gathering at the end of September that sweetest of all autumn Apples, Yellow Ingestre, is useful. It is conical in shape, of a brilliant golden colour, bears regularly and profusely, and keeps soundly for some time. For later use, where the soil is warm and the position sheltered, Cox's Orange Pippin and King of the Pippins may be depended on, but where the conditions are the reverse, Golden Spire and Ross Nonpareil, a very hardy, capital eating Apple, may be substituted with Sturmer Pippin for spring sale. The remarks as to the folly of planting too many soft-fleshed early dessert kinds are equally applicable to cooking Apples. My choice would be Lord Grosvenor, as succeeding where Lord Suffield fails. This last fine pale amber-coloured Apple was, I believe, sent out by a Norwich firm, which would account for it being so extensively planted in Norfolk. Duchess of Oldenburg and Pott's Seedling are useful for early sale. I am aware the Duchess is easily bruised, but its brilliant handsome appearance always takes in the market if a little extra care is taken in the packing. Now Hawthornden is a grand Apple and an early bearer. Lady Henniker, hardy and free, is excellent either for cooking or for dessert. Bismarck is a grand addition to market Apples, young trees bearing well, the fruit having size, colour, and flavour to recommend it. Lane's Prince Albert, too well known to need describing, is A1 in every respect. Alfriston is a fine late-keeping excellent cooking Apple, and so is Normanton Wonder. Blenheim Orange is too long in coming into bearing for the ordinary market grower. The same may be said of Warner's King and Bramley's Seedling. The last fruits earlier when growing in a strong retentive loam.

J. CRAWFORD.

EARLY-FORCED FIGS.

THE Fig is perhaps the most easily grown of all our indoor fruits, and yet how seldom do we see good early crops. This is undoubtedly accounted for by the sensitiveness of its roots to chills or anything approaching sourness in the border. The Fig, if grown in a badly-drained soil, casts its fruits; therefore, anyone embarking on Fig culture should provide thorough drainage for the plants in either pots or borders. For early work pot plants are decidedly preferable to those planted out unless the border can be artificially heated, and, unfortunately, this condition is rarely obtainable. To start, the pots, or tubs as the case may be, should be placed in a bottom-heat of 60°, and the balls of soil kept moistened with water 5° warmer than the temperature of the roots. If need be, stimulants may be used, for Figs are gross feeders, and any assistance in this way will be compensated by the crop. As the season advances, the temperature of the bed and the water employed may be raised to 65° or 70°. The warmth of the house throughout the growing period should be, if anything, below that of the roots. Checks to growth should also be strictly guarded against, for it will be found that a sudden chill is almost as detrimental to a crop as a chill is to the plant's roots.

By carefully carrying out these items in connection with the cultivation of early crops of Figs, there will be little left to be desired in the yield. On the other hand, if only one soaking with cold water be given the roots, the majority of the fruits will drop. With pot or tub culture of Figs, it is never wise to keep old plants, for these gross feeders soon exhaust the limited quantity of soil at their command

of food materials, and the fruits, though plentiful, are so small that they can only be regarded as mere apologies for what they should be. Therefore, in order to maintain a supply of vigorous plants, a few should be propagated annually. With a command of bottom-heat, warm water, and given liberal treatment, cuttings put in in the early months of the year will yield a nice crop of exceptionally fine fruits the following autumn. In one season, too, fairly good-sized plants can be produced for early forcing the following year by attending to stopping and removing all suckers whenever seen.

Figs planted out are more difficult to deal with for early work, as their roots are not generally so well within the command of the grower as are those of pot plants. Nevertheless, much can be done to improve adverse conditions where they exist. In earlier days the requirements of the Fig seem to have been better understood than they are at present, for nearly every house under the old school of management exhibits unmistakable signs of a thorough knowledge of essential root conditions to successful Fig culture. The borders, or rather beds, are raised from 1 foot to 2 feet above the level of the floor, and the staple of which they consist is well mixed with old lime screenings and small pieces of charcoal and broken bricks. Being thus raised the beds attain a temperature similar to that of the atmosphere of the house, and the lime screenings, charcoal and brickbats keep the whole porous and sweet. With trees in borders of this kind and under gentle forcing, and the use of water 10° above the temperature of the house, there is every likelihood of heavy early crops being the result. Alter these conditions to some of our more modern systems, *i.e.*, to level borders, less opening constituents in them, and a disregard of the temperature of the water employed, and what follows? For late supplies, plants grown under these unfavourable conditions may struggle on and yield a moderate crop, as the warmth of the summer's sun will make itself felt in soil and water alike, but early crops from such will be next to impossible. Knowing these facts, we should aim at securing a well-drained, aired and warm medium for the roots of our early forced Figs, and avoid extremes of temperature in the atmosphere of the house.

J. RIDDELL.

Stewed Pears.—A friend of mine having more fruit on a tree of Doyenné du Comice than he thought ought to remain, removed some, and instead of throwing them away had them stewed, and was surprised at the delicious flavour. "It was finer," he said, "than that of any other stewed Pears he had ever tasted." Two other gardeners who tasted them expressed the same opinion. Of course, Pears should be sufficiently thinned out at an earlier stage of growth, but it sometimes happens that gardeners who want fine fruit find it advisable to ease the tree even when the fruit has grown to a good size, and any so doing in the case of Doyenné du Comice might put them to the same use instead of throwing them away. The best way to stew the fruits is, after slicing them, to put them into a syrup in a jar, covering this down, and placing in a fairly hot oven so as to stew slowly. In order that the desirable rich brown colour should be secured, the jar should not be uncovered more than once during stewing.—J. C.

Failure with Raspberries.—I have four rows, each about 30 feet long. The plants are trained to wires. The canes often grow from 8 feet to 10 feet high and are thick in proportion. In the autumn they look most promising and break well, but just after the blooming period they turn yellow and the fruit fails to swell. Nor can

this arise from pruning, as the canes have been left the entire length by bending them over arch fashion when tying them in winter. At other times they have been cut back to about 6 feet high. Summer thinning has been tried, only leaving enough to fill the space, and this, too, early in the season. During the last ten years I have had them replanted three times, and each time in a fresh position. Nor do varieties seem to improve matters, as I have tried four of the best

from the canes not ripening, but this I can hardly think is the cause.—DORSET.

TREES AND SHRUBS.

BENTHAMIA FRAGIFERA.

MANY fine specimens of this handsome plant are to be found in the gardens of South Devon

frost of 1895 temporarily ruined a fine tree in this immediate neighbourhood, which, however, broke into growth again shortly before midsummer, and now appears none the worse for its harsh experience. A sheltered position is to be recommended for the subject of this note, as it rarely forms a symmetrical tree where exposed to the action of rough winds. It is, perhaps, when situated on the

Benthamia fragifera. Raised from seed in the garden of Mr. R. Kelly, Kelly, Lifton, Devon.

and most reliable kinds. The soil is loam, resting on stone. For several years I tried manuring in winter, mulching in summer, and now the last two years I have not given them any at all. I never dig among them, all I do being to simply lightly fork over the surface, removing any surface suckers. The situation is low and damp. It has been suggested to me that the failure may arise

and Cornwall, while it also flourishes in the genial climate of the Channel Islands, and as far east as Hampshire it has attained a large size. Although not particularly tender, having been known to withstand 25° of frost with impunity, it is occasionally badly crippled by a long spell of severe weather. The prolonged

gentle slope of a fairly open grassy glade and backed by tall trees that the beauty of the *Benthamia* is best realised. In such a situation well-furnished specimens present a charming picture when in full bloom, every shoot laden with large widely-spread blossoms, of greenish yellow, thrown into high relief by the darker

background. In the autumn a second season of beauty ensues when the fruits assume that crimson colouring which has given the *Benthamia* its English name of Strawberry Tree. Occasionally specimens are to be found grown in the form of standards with trunks bare to the height of 8 feet or so, but this conformation lacks the grace of the more naturally grown tree and has little to recommend it. I remember some years ago seeing a handsome specimen in the grounds at Fota, Co. Cork, and, earlier still, a large number of exceptionally fine trees at Heligan, St. Austell, Cornwall, some of which, so far as my recollection serves me, must have been 40 feet or more in height. I understood at the time that the *Benthamias* at Heligan were the produce of the first seeds imported into England from Nepal some seventy years ago. It would be interesting to know particulars of the height of these trees at the present time. The Strawberry Tree is easily raised from seed if the fruits, some of which when fully ripe exceed an inch in diameter, be gathered before they are exposed to sharp frosts.—S. W. F., *Torquay*.

Mr. Kelly, Kelly, Lifton, Devon, in whose garden the plant figured is growing, in writing to us says:—

The *Benthamia* is 19 feet wide, 14 feet high, and is growing in front of a Fir plantation with a southern aspect. It was raised from seed sown twenty-four years ago.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 11.

BEYOND any question no better display has ever been brought together in October than that of Tuesday last. In many ways it was a most remarkable one both in variety and general excellence, each committee having before it some high-class productions. That of the fruit committee consisted largely of Apples and Pears, and when it is stated that the Maidstone firm (Messrs. Bunyard) exhibited, no further remarks are needed here as regards the excellence of the produce shown. Another splendid exhibit of Pears came from Mr. Martin Smith, fully demonstrating what may be successfully accomplished under orchard-house culture as well as outside. The floral committee had before it a few high-class groups, but not many novelties. A few fine foliaged plants, however, deservedly received first-class certificates. A grand group of Pitcher Plants from Syon Gardens occupied with distinct effect the central part of the hall. These were suitably arranged with other fine-foliaged plants of neutral colours. On another table was a most charming group of *Begonia Gloire de Lorraine* from Mr. H. B. May. These were most tastefully disposed. Roses came in profusion from both Waltham Cross and Cheshunt. Both of these exhibits included the latest of the late-flowering Teas, &c., from outside, and in addition pot Roses from inside—admirable decorative plants. A most seasonable group of Michaelmas Daisies was staged by the Messrs. Veitch; these were lifted plants in pots; thus the height and character of each plant could at once be seen. Dahlias still linger and a few good blooms were staged, one award of merit, to the surprise of many, being made. Another and a most remarkable exhibit was the hybrid *Rhododendrons* (*Javanico-jasminiflorum* section), of which plants bearing fine trusses were staged in quantity. Herbaceous *Lobelias* from Burford Lodge, Dorking, were thoroughly representative. Orchids were not numerous as regards groups, the largest being of *Dendrobium formosum giganteum* from Gunnersbury House; another of mixed kinds from Enfield, and a pleasing exhibit of *Masdevallia tovarensis* from Cheshunt.

A grand plant of *Vanda Sanderiana* came from the Dulcote collection bearing several spikes of fine flowers. A few superb hybrids were also shown, and a small group from Burford Lodge of rare things was noted. The attendance was fairly good, but the light was sadly deficient. The interior decoration of the hall is not of itself of any assistance in this respect, but rather the reverse, whilst it is sadly in need of a thorough cleaning, the roof in particular, which keeps out practically as much light as it admits.

Orchid Committee.

A first-class certificate was awarded to—

LILIO-CATTELEYA DOMINICANA LANGLEYENSIS.—This was raised by Mr. Seden, and is the result of crossing *Lalia purpurata* and *Cattleya Dowiana*. The sepals are pale rose, mottled with white, the petals of fine form and substance, pale rose, suffused with a darker shade; the broad, finely-shaped lip deep crimson-purple with a darker shade of crimson in the centre, beautifully corrugated and margined with rose; the side lobes crimson, suffused with brown and lined with yellow through the base of the throat. The plant carried a raceme of three flowers. It is one of the grandest hybrids we have seen. From Messrs. J. Veitch and Sons.

Awards of merit were adjudged to the following:—

SOPHRO-CATTELEYA CLEOPATRA (*Sophrontis grandiflora* × *C. guttata* Leopoldi).—An interesting and distinct hybrid, which has flowered in four years from the time of sowing the seed. The flowers have the intermediate characters of both parents, the sepals and petals being of a distinct orange-scarlet, the lip of a brighter hue, with a suffusion of purple and some yellow at the base; the side lobes rose-purple, shading to yellow. The cut raceme carried three flowers. From Messrs. J. Charlesworth and Co., Heaton, Bradford.

LILIO-CATTELEYA HENRY GREENWOOD (*L. C. Sehilliana* × *C. Hardyana*).—In this the sepals are greenish white, slightly suffused with rose, the petals pale lilac, veined and suffused with a darker shade of colour, the whole of the front lobe of the lip rich velvety crimson, the side lobes rose, shading to bright yellow, with some purple at the base. The plant bore two handsome flowers. From Messrs. B. S. Williams and Son.

DENDROBIUM RHODOSTOMA (*D. Huttoni* × *D. sanguinolentum*).—This hybrid was raised some years ago, but has not previously been certificated. The flowers are produced in clusters at intervals along the bulbs. The sepals and petals are white, heavily tipped with deep crimson. The front lobe has a large blotch of deep crimson, the other portion white, spotted with purple, and having some yellow at the base. From Messrs. J. Veitch and Sons.

Messrs. Hugh Low and Co., Bush Hill, Enfield, sent a small but choice group, amongst which was a dark form of *Cymbidium Traceyanum*. This carried a raceme of nine flowers. A fine plant of *Cattleya superba* with two spikes of flower, a dark form of *C. Bowringiana*, *Vanda cœrulea*, a grand form; *Vanda Kimballiana*, *Oncidium ornithorrhynchum album* with four spikes of flower, and *Oncidium cariniferum*, with brown and yellow sepals and petals, and white shading to rose lip, were also included. A good form of *Cypripedium eurandrum*, *C. orphanum*, *C. Sallieri Hyeonum*, and numerous other forms were well represented. *Dendrobium Lowi* with four flowers was very attractive. A silver Banksian medal was awarded. Messrs. F. Sander and Co., St. Albans, sent *Dendrobium puniceum*, a small species carrying its flowers in clusters, the colour pale rose and white; a grand form of *Cattleya Mantini* with four flowers, *Miltonia vexillaria* Leopoldi with two spikes of flower, and a finely-flowered plant of *Stenoglottis longifolia*. Messrs. Paul and Son, Cheshunt, were awarded a silver Banksian medal for a remarkably clean and finely-flowered group of *Masdevallia tovarensis* and *Cypripedium Spicerianum*. Messrs. J. Veitch and Sons sent two fine plants of *Lalia-Cattleya callistoglossa*

(*Lalia purpurata* × *Cattleya Warszewiczii*), the sepals pale rose, with vivid crimson-purple labelum except the rose on the margin and yellow in the base of the throat; *Lalia-Cattleya Nysa* with three flowers, and a large-flowered variety of *Lalia splendens* (certificated last meeting). The grandest display and the most attractive group in the show was the *Dendrobium formosum giganteum* from Messrs. Rothschild, Gunnersbury House. This consisted of thirty-four plants with a total of 675 flowers and buds. We counted sixty-four flowers on one of the plants. In one cluster there were ten blossoms. On some of the baskets seedlings had made their appearance, two and three bulbs being the result of as many years' growth, each bulb making a wonderful improvement on its predecessor. *Odontoglossum grande* and *Vanda Kimballiana* were also well represented. Mr. Hudson is to be congratulated on the wonderful success he has achieved in the cultivation of this somewhat difficult species. A silver-gilt Flora medal was awarded. Sir T. Lawrence sent a small group consisting of varieties of *Cypripedium Lawre-bel*, a finely-flowered plant of *C. regale*, a light form of *Lalia pumila* and a dark form of the true *L. prestans*. *Cattleya St. Benoit* (*C. Schroderae* × *C. Aclandiae*) is very much in the way of *C. Duke of York* and others, the sepals and petals deep rose, the lip rich velvety crimson in the front lobes, the side lobes crimson in front, shading to rose, and white at the base. Two cut spikes of *Lalia-Cattleya exoniensis*, the vivid scarlet *Habenaria militaris*, and *Epidendrum porphyreum*, a distinct variety with large orange sepals, small yellow petals and yellow lip, and a grand variety of *Dendrobium Phalaenopsis hololeucum* with eight of its pure white flowers were also included. Mr. E. Miller Munday, Shipley Hall, Derby, sent a finely-grown plant of *Angraecum ichneumonum* with nine spikes of its small white flowers; Mr. B. B. Baker sent a finely-flowered plant of *Odontoglossum grande* having twenty-five expanded flowers; Mr. W. Cobb, Dulcote, Tunbridge Wells, showed a fine plant of *Vanda Sanderiana* with five spikes of its remarkable rose and brown flowers, a good plant of *Cypripedium Lawre-bel* and *C. Percival Cobb*, in the way of *C. Hyeonum*. Mr. W. A. Bilney, Weybridge, had two finely-flowered plants of *Lalia pumila*; and Mr. R. B. White sent a *Cypripedium bellatulum* hybrid, in the way of Charles Richman, the flower much deformed.

Floral Committee.

The following received first-class certificates:—

LINOSPADIX PETRICKIANA.—A beautiful and graceful Palm from New Guinea, resembling in growth some species of *Geonoma*, but generally more sturdy-looking. It is of dwarf habit, the pinnate fronds gracefully arched, and in a young state assuming a light bronzy hue, a characteristic more or less of the species from this part of the globe. Two beautiful plants were shown. From Messrs. F. Sander and Co., St. Albans.

ALOCASIA SPECTABILIS.—A very striking and handsome kind, the leaves each about 18 inches long and 9 inches broad, the rachis pale green, the veins also somewhat raised, the whole surface having a silvery appearance. From Messrs. Jas. Veitch and Sons, Chelsea.

The following received awards of merit:—

CHRYSANTHEMUM JULES MARQ.—A decorative kind of a very desirable shade of brownish crimson, the flowers of medium size and inclined to semi-reflexed form. From Mr. Wells, Eurlwood, Redhill.

DAHLIA EBONY (Cactus).—A flower of medium size and of a rich crimson-maroon shade, very dark in the centre. From Mr. Mortimer, Farnham, Surrey.

DRACENA ECKHARTII.—This is one of the green-leaved type, and, judging by appearance, should prove a useful hardy kind. The plant shown was 3 feet high, the leaves scarcely so broad as in *D. terminalis* or *congesta* forms, decidedly more graceful and drooping, and more closely arranged on the stem. The foliage, too, is exceptionally dark in colour. Smaller examples would make

good table plants. From Messrs. Jas. Veitch and Sons, Chelsea.

Of Pitcher Plants, Mr. Geo. Wythes, The Gardens, Syon House, Brentford, staged a handsome group. This was, perhaps, the largest and most complete collection both of species and hybrids ever brought to the Drill Hall, several of the kinds being very rare. In all there were some thirty species and hybrid varieties of these highly interesting plants. *Nepenthes gracilis* major, a small-pitched kind, appears insignificant against such handsome sorts as *Dicksoniana*, which has very handsome cups, chequered crimson. *N. Courti* has medium-sized pitchers, narrow and freely checked with green; *Intermedia* is a vigorous sort, the pitchers finely hooded and marked with crimson and green; *Mastersiana* has a nearly self-coloured pitcher of a crimson-brown hue, long and very handsome; *Morganie* is a smaller kind, of a chestnut-brown hue, while the well-known *Rafflesiana*, with its 2 feet or more of attenuated midrib, is ever a conspicuous kind. Several fine plants of *N. mixta*, each with grand pitchers, were very noticeable, the apex in this being beautifully recurved and lined or ribbed, the glossy crimson hue over all lending a charm almost unique. *N. Hookeriana* is of more globular form, and the singular green of *N. phyllanthora* appears in striking contrast to the handsomely-shaped cups of *N. Amesiana*, a bold and prepossessing form, darkly spotted, while *N. Chelsoni*, in the same way, is pale green, with light crimson spots and markings. *N. sanguinea*, one of the rarest of the old kinds, had three grand pitchers. Other good kinds are *Veitchi*, *Wittei*, *Hookeriana elongata*, *Curtisi superba*, *hirsuta glabrescens*, pale green; *hevis*, also green; *Wrigleyana*, medium, but very profuse; *cylindrica* and *formosa*, with large showy pitchers on long pendants. The plants were tastefully arranged, and in a manner that displayed the characteristics of the abundant pitchers to advantage, a few large *Cocos plumosa* in the centre, with *Eulalias*, *Arecas*, *Adiantum Farleyense*, and other Ferns forming a pleasing groundwork. Some plants of *Pinguicula caudata* in pans, the pretty New Holland Pitcher (*Cephalotus follicularis*) also in pans, *Sarracenia purpurea*, and *S. Chelsoni* rendered the group as a whole more replete. A silver-gilt Flora medal was awarded. Another very charming group that also displayed high cultural skill as well as good taste in arranging was that from Mr. H. B. May, Edmonton, composed mainly of *Begonia Gloire de Lorraine*, the plants splendidly grown and covered with blossoms in the most perfect manner. Very remarkable, too, was the size of plant compared with that of the pot, the latter generally about 5 inches across. The plants were the most perfectly grown examples we have seen, and were raised amid a series of pleasing and beautiful Ferns that favoured a sort of transparent view of the whole, the finely-developed fronds of *Adiantum Farleyense* being seen to advantage. These, with a few *Pterises*, some small *Eulalias*, *Bouvardias* and *Solanums*, the last well berried and finely coloured, completed a very interesting group (silver-gilt Flora medal). From Chelsea Messrs. Jas. Veitch and Sons brought a nice lot of the javanic-jasminiflorum hybrids of *Rhododendrons* in much variety, the whole arranged in a bed of Maiden-hair Fern—*Hercules*, orange; *Carmine*, orange; *Apollon*, orange-bronze; *Primrose*, pleasing yellow; *Ajax*, cerise-salmon; *Ruby*, dark wine colour; *Maiden's Blush*, and *Souv. de H. Mangles*, deep salmon with orange, being the best (silver Banksian medal). Sir Trevor Lawrence, Burford Lodge, Dorking (gardener, Mr. Bain), brought a few choice hybrid *Pentstemons*, the spikes, as also the flowers, in fine condition for so late in the season. Very fine, too, were the hardy *Lobelias* from the same source. *Carmine Gem* is a most conspicuous kind; the old *Queen Victoria* and *Prince Arthur*, of a similar though brighter shade of vermilion, are excellent, though perhaps too near alike in colour for planting in close proximity. *Crim-*

son Gem is a very dark ruby-crimson. A fine lot of trusses of *Verbena Ellen Willmott* showed this to be a fine kind for the flower garden. A fine assortment of *Michaelmas Daisies* in pots from Messrs. James Veitch and Sons was arranged in a half-circular group near the entrance, and from many points of view may be regarded as excellent. The varieties were both numerous and good as well as representative. Among the most effective were *A. turbinellus*, a very elegant kind, with solitary flower-heads on long slender stalks; *A. diffusus horizontalis*; *Mrs. W. Peters*, white; *Novi Belgii densus*; *A. cordifolius*, very pretty; *Coombeishaere*, fine bushes, 3 feet through; the pretty *ericoides*; *A. dumosus* and *A. Arcturus*, with violet blossoms and dark stems; *Top Sawyer*, a showy kind; *cordifolius major*, a pretty mass of flowers; *acris*, starry blue flowers, and the several varieties of *Novae-Angliae*, which are among the showiest of all. *Stokesia cyanea* in flower was also included in this group, and several forms of *Torch Lilies* that materially enlivened the group as a whole (silver Flora medal). Messrs. F. Sander and Co., St. Albans, had a nice group of *Acalypha hispida*, *A. Godsetiana*, *Dracena Sanderiana* and other things. Flower-heads of that very scarce and striking plant, *Trichinium Manglesi*, were sent from the Botanic Gardens, Glasnevin, and are ever admired for their beauty. Mr. T. S. Ware, Tottenham, had a mixed arrangement of single Dahlias, particularly good, seeing the very severe frost experienced in so many localities, but which has not in any degree disfigured these, the flowers being as fresh and bright as ever. A selection of *Michaelmas Daisies* included *Archer-Hind*; *A. cordifolius elegans*, *A. Amellus elegans*, *A. A. bessarabicus*, *A. A. b. densus*, &c. *Lilium neilgherrense*, several *Tritomas*, notably *T. Macowani* and *Solfaterre*; *Stokesia cyanea*, *Eryngium Oliverianum*, and a few *Bamboos* and grasses were also shown. Hybrid *Pentstemons* from Messrs. Veitch and Sons, together with a grand lot of spikes of *Physalis Franchetti*, the monster richly-coloured calyces, averaging eight to ten on a spike, being very showy.

Roses for the season of the year were good. Messrs. Wm. Paul and Son, Waltham Cross, having a fine lot of pot plants, mostly Teas, and of these suitable sorts for winter flowering, the more beautiful are *Grace Darling*, *Niphetos*, *Bridesmaid*, *Catherine Mermet*, *Mrs. F. Bennett* (rose-crimson), *Mme. Hoste*, *Souvenir d'un Ami*, *Jean Ducher*, *Queen Olga of Greece* (a lovely salmon shade), *The Queen*, *The Bride*, *Mme. Cusin*, &c. There was also a fine assortment of cut blooms in variety, including *Caroline Testout*, *Ma Capucine*, *Mme. Rene Gerard* (an improvement in vigour on the last and in the same way of colour), *Maman Cochet*, and others (silver Flora medal). From Oxford, Mr. Geo. Prince brought a few exquisite *Roses*, particularly *The Bride*, *Maman Cochet*, *Souvenir de Mme. Perrier* (guillot (copper or orange-bronze) *Princesse de Sagan* (a fine crimson), *W. A. Richardson*, &c. Another set of *Roses*, mostly cut, came from Messrs. Paul and Son, Cheshunt. These were grouped in a free manner in baskets, and included such kinds as *Mme. de Watteville*, *Sunset*, *l'Idéal*, *Bridesmaid*, *Gustave Regis* (good yellow), *A. K. Williams*, *Mrs. J. Laing*, *Perle d'Or*, *Captain Christy*, *Alba rosea*, *Mme. P. Cochet* (rich orange), *Mme. Cochet*, *Perle des Jardins*, *Mme. Falcot*, and many others, thus showing the tendency of the season following the great heat and drought. Included in Messrs. Paul's group was *Desmodium penduliflorum*, a flowering climber of a pleasing character not often seen (silver Flora medal).

Fruit Committee.

There was a large number of interesting exhibits before this committee, including a splendid lot of fruit from Maidstone, Pears also from Kent, and a goodly number of new fruits, Melons being better than usual.

Awards of merit were given to the following:—

MELON WYTHES' SCARLET.—A medium-sized fruit, skin greenish yellow, densely netted, flesh

of great depth, scarlet. It is a cross between Syon House and Syon Perfection, and a particularly good flavoured fruit. From Mr. Wythes, Syon House, Brentford.

MELON GUNTON SCARLET.—A medium-sized Melon, of excellent quality, skin bright yellow, netted, flesh scarlet, of good depth. It is a cross between Gunton Orange and an old variety, is very sweet and a free cropper. From Mr. Allan, Gunton Park Gardens, Norwich.

PLUM PRIMATE.—A beautiful fruit, as large as Monarch, nearly round, with a lightish bloom, a dark red skin, and of excellent flavour. Though evidently a cooking fruit, it is at this season not out of place for dessert. From Messrs. Rivers and Son.

APPLE MRS. JOHN SEDEN.—A brightly coloured small fruit, a seedling from King of Pippins and the Transparent Crab. It has a brisk flavour, the flesh firm and the tree an enormous cropper. This will make a nice addition to the dessert Apples at this season. From Messrs. Veitch, Ltd., Chelsea.

APPLE INVINCIBLE.—One of the handsomest Apples the fruit committee have had before them. It is a very large cooking Apple, green on the shaded side and bronzy red where exposed, somewhat conical, with a deep eye, and in season from October to January. From Mr. D. Bodaly, Towcester.

Messrs. Bunyard and Co., Maidstone, sent 100 dishes of cooking Apples, doubtless the cream of those staged at the recent fruit show. It was a difficult matter to select any one variety, all being so good. The magnificent Peasgood's Non-such, though doubtless grown under glass, was most noticeable, this forming the centre of the collection. Royal Jubilee and Cornish Giant were extra fine and the colour of such kinds as Baumann's Red Reinette, Mère de Ménage, Emperor Alexander, Duchess of Oldenburg, The Queen, and Yorkshire Beauty was wonderful. Potts' Seedling, Lord Derby, Lord Grosvenor, Warner's King, Bow Hill Pippin, Newton Wonder, Belle de Pontoise, Foster's Seedling, Castle Major, Glamis Castle, Lane's Prince Albert, Mrs. Barron, and Farmer's Seedling were noted for their large size (silver-gilt Knightian medal). A fine collection of Pears for the season came from Mr. Blick, The Warren Gardens, Hayes, Kent. In this collection every dish was good, specially noteworthy being *President Drouard*, *Souvenir de Congrès*, *Beurré Diel*, *B. Supertin*, *B. Bachelier*, *B. Bose*, and *B. Rance*. *Doyenné du Comice*, *Duchesse d'Angoulême*, *Marie Louise d'Uccle*, *Princess*, *Magnate*, *Winter Nelis*, *Emile d'Heyst*, and several stewing varieties were also good (silver-gilt Knightian medal). A smaller collection of Apples and Pears, some eighty dishes in all, came from Mr. Rickwood, The Gardens, Fulwell Park, Twickenham. The fruits were a little smaller than those from Kent, but a nice lot. *Duchesse d'Angoulême* Pear was good, also such kinds as *Beurré Superfin*, *Beurré d'Amanlis*, *Beurré de l'Assomption*, *Durondeau*, *Princess*, and *Easter Beurré*. The best Apples were *Alfriston*, *Ecklinville*, *Blenheim Orange*, and *Wellington*, with good dishes of such dessert kinds as *Ribston Pippin*, *Cox's Orange*, *Fern's* and *Sturmer Pippins* (silver Knightian medal). Messrs. Cannell and Sons, Swanley, staged a large number of Onions, *Ailsa Craig* being one of the best. The *Lord Keeper*, *Cocoa-nut*, *Somerset Hero*, *Sandy Prize*, *Ringleader*, *Danver's Yellow*, *Masterpiece*, and *Rousham Park* were also good (silver Knightian medal). Mr. W. R. Green, Wisbech, Lincoln, staged nearly forty dishes of Potatoes, nice clear tubers, and not too coarse. *Snowdrop*, *The Bruce*, *The Saxon*, *Read's Giant*, *The Norwich*, a nice tuber, *Satisfaction*, *Duke of York*, *Magnum Bonum*, and *British Queen* were very fine (silver Banksian medal). A very fine Peach, named *Princess May*, was sent by Mr. Sheppard, Maidstone. This was a seedling from the *Victoria Nectarine*. The fruits were large, of a pale colour, and of excellent quality, but too ripe. The committee wished to see it next season. *Apple Bedfordshire Green*—

ing came from Mr. Empson. A new seedling from Blenheim Orange was sent, but not of good quality; no card appeared on this exhibit and on several others also. A new Apple, Castle Favourite, from Messrs. McCreedy and Son, Portsmouth, was much too ripe. Melons came from some half-dozen sources, one from Mr. Empson and another from Mr. List, Lydney Park Gardens, Gloucester, being much too ripe. Fruits of *Ficus repens* came from Mr. Williams, Whitbourne Hall Gardens, Worcester. A green-skinned Tomato, but lacking quality, called Greengage, came from Mr. White, Blythwood Gardens, Maidenhead. A dish of the new St. Joseph Strawberry and some leaves of Tomatoes from the secretary showed the formation of young plants on the old foliage in much the same way as is usual with Ferns.

NATIONAL CHRYSANTHEMUM SOCIETY.

OCTOBER 11, 12, AND 13.

THE exhibition which was held on the above dates at the Royal Aquarium, Westminster, far exceeded the expectations of most persons. The display on the present occasion was one of the very best ever held at this season, the whole of the ground floor being well filled, both tabling and floor space being insufficient to meet the demands of exhibitors, several very handsome exhibits being staged in one of the galleries. The show on the present occasion cannot be considered one of Chrysanthemums absolutely, as by far the greater space was occupied with exhibits of a miscellaneous character. Chrysanthemums certainly were well represented, the quality distinctly in advance of what was anticipated. Blooms almost equal to the standard obtained a month later were staged, the competition in the several classes being distinctly good.

CHRYSANTHEMUMS—OPEN CLASSES.

For a group of Chrysanthemums and fine-foliaged plants arranged for effect in a space covering 72 superficial feet, Mr. J. Spink, Summit Road, Walthamstow, was first, the plants carrying excellent flowers. These were charmingly disposed in the group, and mixed with a few good examples of *Cocos Weddelliana* and a fringe of other fine-foliaged plants, a very good effect was produced. The colours and form of the Chrysanthemums were wonderfully good. The second prize fell to Mr. W. Howe, gardener to Sir Henry Tate, Park Hill, Streatham Common, S.W., who had a most imposing display, the plants much taller. These were too tightly packed together, much of the beauty of the group thereby being lost. Fine-foliaged plants were freely used in this group. Cut flowers in the open classes were represented in capital form and colour. There were four competitors in the class for twenty-four Japanese, not less than eighteen varieties and not more than two blooms of a variety. Mr. James Brooks, gardener to Mr. W. Newman, Totteridge Park, Herts, was first, flowers of special merit being Mons. Gustave Henry, a fine October white; Sunstone, Oceana, wonderfully good this season; Mutual Friend, Mrs. G. W. Palmer, the crimson-bronze sport from Mrs. C. Harman-Payne; Ella Curtis, Phœbus, Emily Silsbury, a grand October white; and Mrs. C. Harman-Payne among others. Mr. H. Shoesmith, Claremont Nursery, Woking, was a capital second, his exhibit containing several flowers of very high quality, conspicuous among them being Mme. G. Bruant in grand form for this rather coarse flower; E. Molyneux, M. Gustave Henry, Werther in splendid condition, Red Warrior, Master H. Tucker, Pride of Madford, good in colour, and International. There were four competitors in the class for twelve Japanese, distinct, and the first prize exhibit probably contained the best blooms in the show. They were characterised by good form, bright and rich colours, also depth and substance. These came from Mr. John Fulford, gardener to Mr. F. D. Lambert, J.P., Moor Hall, Cookham, Berks, and were represented by Ella Curtis, Mons. G.

Biron, as fine in colour as we have seen; Mrs. J. Shrimpton, Oceana, Dorothy Seward, Elthorne Beauty, Reine d'Angleterre, Mr. F. Brewer, Mrs. J. Lewis, Iserith, Mons. Pankoucke, and a grand white seedling not unlike Lady Byron. To Mr. R. Jones, gardener to Mr. C. A. Smith Ryland, Barford Hill, Warwick, second prize was awarded, the best flowers being M. Gustave Henry, Mutual Friend, John Seward, G. C. Schwabo and George Seward. In the class for six blooms Japanese, distinct, six competitors entered, the quality being good throughout. Mr. James Brooks was first, having good blooms of Oceana, M. Gustave Henry and Pride of Madford. There were several competitors for six blooms Japanese, one variety only, white sorts predominating. Mr. R. Gladwell, gardener to Mr. Sydney Smith, Wernden Hall, South Norwood, S.E., was placed first with six fine examples of Mme. G. Bruant. Mr. J. Brooks followed with flowers of M. Gustave Henry. Incurved flowers at this show are generally weak. The first prize was won by Mr. Robert Bassil, gardener to Mr. D. H. Evans, Shooters Hill House, Pangbourne, his varieties being D. B. Crane, Baron Hirsch and Mons. R. Bahuant, all more or less rough. The same remark applies to the second prize stand, which came from Mr. T. Robinson, gardener to Mr. W. Lawrence, J.P., Elfield House, Hollingbourne, Kent. For twelve bunches pompons, a poor lot secured leading position, Mr. S. J. Cook, gardener to Mr. A. N. Stephens, Holmbush, Hendon, showing Black Douglas, Mme. E. Lefort and Piercy's Seedling in good form. For six bunches pompons, Mr. T. L. Turk, gardener to Mr. T. Borrey, Southwood House, Highgate, was first, especially noticeable being Mlle. Elise Jordan, Osiris, Vésuvé, Nellie Rainford, Veuve Chiquot and La Vogue.

In the amateur division for twelve Japanese blooms, distinct, Mr. Gladwell was awarded first prize for a bright lot of flowers. First prize was also secured by Mr. Gladwell for six Japanese blooms, distinct, second prize being awarded to Mr. W. Perrin, Sawbridgeworth. In the division for twelve bunches pompons, Miss Debenham secured leading honours, having Flora, Mme. Gabus, M. Herlaut, and Longfellow in pleasing condition. For twelve Japanese, not less than six varieties, first prize fell to Mr. W. G. P. Clark, Verulam Road, Hitchin, Herts, with a meritorious lot of flowers. A close second was found in Mr. H. Love, 1, Melville Terrace, Sandown, Isle of Wight, who had a pretty rose-tinted seedling from Mrs. H. Weeks in his stand of flowers.

DECORATIVE CLASSES.

For a table of bouquets, wreaths, sprays, button-holes, &c., illustrating the decorative value of the Chrysanthemum, only two exhibitors entered, the premier award falling to the lot of Miss Nellie Erlbach, assistant to Mr. J. R. Chard, The Florist, Stoke Newington, N., who had a very large though cumbersome arrangement. The best floral designs were a lovely anchor in yellow Chrysanthemums with a chain of Barberries, a white wreath, a lyre, and a pretty yellow-coloured bouquet. Mr. J. Emberson, Grove Road Nursery, Walthamstow, was second, the choice of colour in his designs considerably hampering him in the competition. A charming wreath on his table was deserving of special notice. The competition for three stands of Chrysanthemums suitable for table decoration was, as usual, very keen, six exhibitors with a 9 feet run of tabling making a delightful display. Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, again maintained his position with a lovely array of autumnal and other foliage in association with yellow, orange, and crimson Chrysanthemums. A few more bright yellow flowers only seemed wanting to make the blending of colours well balanced. Mr. W. Green, jun., The Florist, Harold Wood, Essex, was placed second with a charming arrangement of yellow flowers and bright green foliage, and the judicious use of highly-coloured Virginian Creeper as a contrast. For two vases of exhibition Japanese blooms, each

vase to contain twelve blooms, with the addition of suitable foliage, leading honours fell to Mr. W. Measo, gardener to Mr. A. Tate, Downside, Leatherhead, with a grand lot of flowers. The second prize was secured by Mr. James Brooks with a much lighter arrangement, but lacking quality in the flowers. A spirited competition ensued for a vase of pompon blooms arranged for effect with suitable foliage. In this class Mr. W. Green, jun., Harold Wood, was first, with a lightly arranged lot of flowers, but rather overdone with Asparagus foliage. In the amateurs' division for a single vase of Chrysanthemums for table decoration, Mr. D. B. Crane found most favour, his selection of mauve-pink and white Chrysanthemums looking somewhat dull under the brownish light of the Aquarium roof.

VEGETABLES.

The removal to the Royal Aquarium of Mr. Henry Deverill's Pedigree Onion and other choice vegetables' exhibition created considerable interest. For the best twelve Ailsa Craig or Cocoa-nut Onions, a grand lot secured for Mr. W. Fyfe, Lockinge Gardens, Wantage, first prize. These were large, well-ripened specimens, and according to the card scaled 30 lbs. A good second was found in Mr. John Masterton, Weston House Gardens, Shipston-on-Stour, who had very large roots, but not so well finished. For six Onions the same as those asked for in the leading class, Mr. Fyfe was again first, with large typical roots of Ailsa Craig, again followed by Mr. Masterton, with smaller and less pretty specimens. In the class for twelve best Onions selected from either Anglo-Spanish, Lord Keeper, Royal Jubilee, and Rousham Park Hero, Mr. Fyfe again maintained his position with handsome specimens of Lord Keeper, second prize going to Mr. T. Wilkins, The Gardens, Inwood House, Henstridge, with rather irregular specimens of Anglo-Spanish. For twelve Improved Wroxton Onions, Mr. Wilkins was placed first, with nice, well-ripened and neatly-finished bulbs, Mr. W. F. Wyton, Crookhey Hall, Garstang, Lancs, securing second place with smaller roots. For six Oxonian Leeks, a magnificent and even lot from Mr. David Gilson, gardener to Mr. J. B. Johnstone, Coombe Cottage, Kingston-on-Thames, secured premier honours. To Mr. R. Lye, gardener to Mrs. Kingsmill, Sydmonston Court, Newbury, second prize was awarded. For twelve Exhibition Scarlet Intermediate Carrots there were no less than a dozen competitors, those from Mr. J. Masterton finding most favour with the judges, although they appeared to be a trifle coarse. Smaller specimens secured second prize for Mr. T. Wilkins. The competition was keen in the class for twelve specimens Middleton Park Favourite Beet. In this class Mr. E. Beckett, gardener to Lord Aldenham, Aldenham House, Elstree, Herts, was a good first with wonderfully even specimens, Mr. J. Bowerman, gardener to Mr. C. H. Hoare, Hackwood Park, Basingstoke, being second. Mr. Beckett was again first for six sticks Aylesbury Prize Red Celery, Mr. J. Bowerman being placed second. For twelve Improved Hollow Crown Parsnips Mr. Beckett again proved his superiority with long clean specimens, Mr. R. Lye following with shorter and less even specimens. Out of five competitors for twelve fruits Glenhurst Favourite Tomato Mr. Beckett was again first, second prize falling to the lot of Mr. T. Wilkins with much smaller, though pretty specimens. The competition for a collection of vegetables in eight distinct kinds was without doubt the most important of the series, and in this class there were no less than six entries. Mr. Beckett was first, and it is very doubtful if a finer lot of vegetables has ever been staged so early in the autumn. No fault could be found with a single dish. Mr. R. Lye followed closely, showing wonderfully well. For the twelve largest and hand-somest of any pedigree Onions there were thirteen competitors, first prize being taken by Mr. T. A. Beckett, Havering Park, Romford, with Ailsa Craig, closely followed by Mr. James Bell 80, High Street, Berkhamsted.

MISCELLANEOUS EXHIBITS.

Among these the place of honour must be given to the group of Chrysanthemums and fine-foliaged plants arranged by Mr. H. J. Jones, Rycroft Nursery, Hither Green, Lewisham, S.E., who secured the large gold medal of the society. The group measured 30 feet by 15 feet deep, and was backed by graceful Bamboos. The back of the group was arranged in three semi-circular banks, the front being finished off with a series of circular groups, in which highly-coloured Crotons and Palms were tastefully associated. A fringe of Ferns and *Isolepis gracilis* gave a pretty finish. The Chrysanthemums were mostly novelties and of considerable promise. Another leading feature of the exhibition was the superb collection of Michaelmas Daisies, arranged with great taste by Mr. Norman Davis, Framfield, Sussex, in the gallery. Rarely, if ever, has there been such a fine exhibit of these hardy flowers. Several handsome seedling flowers from *Aster Amellus* were in evidence. One particularly good one, flowering three weeks later than most of the type, is *A. Amellus Framfieldi*. A small gold medal awarded this collection was well merited. Mr. E. Beckett also staged a very fine representative lot of bunches, including several charming novelties, receiving a silver-gilt medal. Dahlias were staged by Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, and given a silver-gilt medal. Mr. S. Mortimer, Swiss Nursery, Farnham, Surrey, also had an immense array of Cactus, show and fancy Dahlias; a silver-gilt medal was awarded. Fruit in splendid condition came from several well-known trade exhibitors. Mr. H. Berwick, Sidmouth Nurseries, Sidmouth, Devon, was awarded a silver-gilt medal. Messrs. J. Laing and Sons, Forest Hill, Messrs. W. Cutbush and Sons, Highgate, N., and Messrs. S. Spooner and Sons, Hounslow Nurseries, Middlesex, each received a silver medal. Mr. H. Deverill, Cornhill, Banbury, had a large table of hardy herbaceous flowers (silver medal). Messrs. H. Cannell and Sons, Swanley, set up a pleasing group of Cannas, also a table of Chrysanthemums, receiving a silver medal. Mr. W. Wells, Earlswood Nurseries, Redhill, Surrey, had a large group of Chrysanthemums on single stems, and as a base a huge quantity of hardy border sorts. We should have preferred these latter on a table by themselves, where their value would have been fully appreciated by those interested in an outdoor display, for which this type of the plant is so admirably adapted (silver-gilt medal). From Mr. W. J. Godfrey, Exmouth, Devon, came a large table of Chrysanthemum novelties, many of them of great promise. To these, together with a useful lot of Carnations, a silver medal was given. Mr. Robt. Owen, Maidenhead, had a small table of Chrysanthemums, including some handsome Japanese novelties (bronze medal), and a pretty group of a new early Chrysanthemum Mrs. Wingfield, a pleasing shade of flesh-pink, was arranged by Messrs. R. and G. Cutbush, The Nurseries, Southgate, N.

FLORAL COMMITTEE.

There was a fully-attended meeting of the floral committee on Tuesday last, under the presidency of Mr. Thos. Bevan. Novelties were freely, and, as a rule, well shown, but only four first-class certificates were given, viz., to—

CHRYSANTHEMUM RAYONNANTE.—A very large tubular-petalled Japanese variety, with long stiff florets of a pleasing shade of pale pink. Shown by Mr. H. J. Jones, of Rycroft Nursery, Lewisham.

CHRYSANTHEMUM MR. F. BREWER.—A Japanese kind with deeply-grooved florets and of great breadth, making up a flower of good exhibition build. The centre florets are deep golden-yellow, being paler towards the exterior, reverse pale straw-yellow. From Mr. R. Owen, Maidenhead.

CHRYSANTHEMUM REGINALD GODFREY.—This is a closely-built Japanese, having flat reflexing florets, the colour of which is deep reddish terracotta with golden reverse, and was shown by Mr. Godfrey, of Exmouth.

CHRYSANTHEMUM SOLEIL D'OCTOBRE.—A French seedling of promise. It is a medium-sized Japanese October blooming variety of a very pure shade of pale canary-yellow. This also came from Mr. Godfrey.

Among others staged at the meeting were Werther, a richly-coloured large Japanese of purple-amaranth; Lord Coleridge, a yellow incurved, which the committee wished to see again; Mrs. W. Seward, after the style of M. Chenon de Leché, but perhaps a little richer in tone; and Crimson Marie Massé, a free-flowering sport from the rosy pink early sort, Mlle. Marie Massé.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

The annual dinner of this flourishing benefit society was held on Wednesday evening, October 5, in the Holborn Restaurant, Mr. Geo. Bunyard, of The Nurseries, Maidstone, in the chair. Among those present we noticed Messrs. N. N. Sherwood, H. B. May, J. G. Veitch, W. Nutting, J. G. Ingram, H. Laing, H. Weeks, besides many members and friends. The usual loyal toasts having been given and duly honoured, the chairman proposed "Success to the United Horticultural and Benefit Provident Society," and in the course of his remarks said that the society had on its books at the present time 728 benefit members, 64 new ones having joined since the beginning of the present year. Mr. Bunyard said it was not necessary for him to show the need of such a society, as the gardener's lot was a hard one and very often he was not paid as he should be. There comes a time when illness overtakes him, and then he finds the benefit of belonging to such a society as this, which is doing excellent work and filling a large gap. He urged on all present to try and get new members, either benefit or honorary, as many of those who joined early will soon be drawing their money out. This society gives 3 per cent. on the money paid in by members—surely an encouragement for others to invest.

Mr. J. Hudson, the treasurer, responded, and hoped that the society would soon number 1000 members. Young gardeners especially should carefully read the rules, and, after thinking the matter well over, at once resolve to join. He was glad to say that the invested funds were steadily increasing, last year by £100, and he hoped that this year would see a still further increase. The invested money per member in this society was greater than in any other he knew. The working expenses, too, were very low. The toast of "The Honorary and Life Members" was proposed by Mr. N. Cole, one of the original members of the society, who said that twelve years ago there were only eight honorary members, while to-day there are over fifty, including three lady members. He thanked the nurserymen for the interest they had taken in the society. Mr. J. H. Veitch replied in the absence of Mr. Sherwood, who had to leave early. He was very much impressed with the solidity of the society, and threw out the suggestion that if all foremen gardeners were approached and the benefits of the society laid before them, they would, he thought, at once join. Mr. T. Winter proposed the toast of "The Visitors," to which Mr. S. T. Wright, of the Royal Horticultural Society's gardens, responded. Mr. H. B. May proposed the health of the chairman, which was enthusiastically received. Mr. Bunyard, having responded in a few well chosen words, read the following list of donations, viz., Mr. L. de Rothschild, £1 ls.; Mr. Garcia, £1 ls.; Mr. G. Monroe, £1 ls.; Mr. J. Watkins, £1 ls.; Mr. Sherwood, £5 5s. to the Convalescent Fund; Mr. J. H. Veitch, £3 3s.; an anonymous donor, £1 ls.; Mr. Cox, £1 ls.; Mr. S. T. Wright, 10s. 6d.; Mr. R. Dean, 10s. 6d.; and Mr. Pinches, 10s. 6d. "Kindred Societies" was proposed by Mr. Ruppell, and replied to by Mr. Ingram, the energetic secretary of the Gardeners' Benevolent. Mr. R. Dean gave "The Horticultural Press," which was

responded to by Mr. Geo. Gordon. The secretary of the society (W. Collins) thanked the donors of fruit and flowers, this being replied to by Mr. J. McKerchar. The musical arrangements were in the hands of the Lamb Brothers' Glee Club, who gave during the evening several songs, part songs and instrumental solos.

At the quarterly meeting one of the oldest members, having attained the age of seventy years, was allowed to withdraw £6 from the sum standing to his credit (nearly £80) in the ledger, the balance being left in the society to accumulate for the benefit of his wife. He at the same time was allowed a sum of 8s. per week from the Benevolent Fund, being now incapacitated from work. This sum, to be paid him quarterly till the end of his life, is more by 16s. a year than the pension granted to aged gardeners in the Gardeners' Royal Benevolent Institution.

Rosebery Avenue.—The London County Council have informed the Clerkenwell Vestry that they will accept the latter's offer of £100 for the small triangular plot of land at the Farringdon Road corner of Rosebery Avenue, on condition that the Vestry will pave it, plant it with trees, and maintain it as an open space, a condition with which, it is understood, they are ready to comply.

The weather in West Herts.—Since the beginning of the week a considerable fall in temperature has taken place. This has been more marked in the case of the nights than the days, the readings of the exposed thermometer on those preceding the 6th and 7th being respectively 54° and 51°, whereas on each of the last four nights the same thermometer has fallen below 35°, and on the coldest of these registered 3° of frost. At 2 feet deep the ground is now 3° warmer, and at 1 foot deep 1° warmer than the October averages for these depths. Some rain fell on three days during the week, but to the total depth of only about a tenth of an inch, consequently the percolation has again quite ceased through both gauges. The winds have been light, and the atmosphere as a rule very damp. The record of bright sunshine proved very poor, averaging only about an hour a day, while four days were altogether sunless.—E. M., *Berkhamsted*.

A late transplanting season.—According to the calendar we should now be busy executing orders for Roses, Gooseberries, Currants, trees, and conifers, and even lifting some few Pears and Plums for orders. But, alas! the land is as dry as possible, and below the surface as hard as a brick, making all this work impossible. Meantime we are bombarded with letters, such as "I am told now is the very best time to remove the things I ordered;" "If you are unable to supply what I ordered, you should have said so at the time;" "Unless my order is forthwith executed, please consider it cancelled." Well, what for a remedy? Why, patience. Practically the season is three weeks late, and as no fibrous roots can be got out of the hard soil, trust to the nurseryman to do his best. Apples are yet in full growth, and practically a week's heavy rain is wanted before lifting can be started.—GEORGE BUNYARD, *The Royal Nurseries, Maidstone, October 10*.

Name of fruit.—*Addison Brown*.—Box and contents received smashed.

Names of plants.—*A. Sadler*.—*Ilabenaria* *Susanne* (H. gigantea, *Bot. Mag.*, t. 3374).—*J. S. S.*—1, *Clematis connata*; 2, *Clematis orientalis* (quite hardy).—*W. Richardson*.—*Hibiscus syriacus* *albus plenus*.—*J. M. V.*—*American Burr Oak* (*Quercus macrocarpa*). The cone-shaped growth produced is the larva of an insect; it has nothing to do with the *Acorus* or with seed-bearing at all.—*Con.*—1, *Retinospora plumosa*; 2, *Cupressus Lawsoniana*; 3, *Cupressus Lawsoniana flavescens*; 4, *Biota orientalis*; 5, *Cupressus Lawsoniana*; 6, *Pyrus Aria*; 7, *Kerria japonica flore-pleno*. The Cape Gooseberry is *Physalis odulis*.—*Querist*.—*Lamium glechomoides*.

CHRYSANTHEMUMS.

RUST IN CHRYSANTHEMUMS.

I AM sorry not to be able to give such a satisfactory account of Chrysanthemums as that given by "Suffolk" in a recent issue. I never knew such a troublesome season, especially with insect pests. For some months, a small, but particularly lively species of thrips gave a great deal of trouble, and seemed proof against all insecticides that could be used with safety, while its activity and powers of jumping stood it in good stead when attempts were made to capture it by other means. It confined its operations to the extreme points of the shoots, where it could easily find shelter, and sucked the plant's juices to such an extent, that the leaves, and later on the flower-bracts, assumed a rusty appearance, and were hard and brittle to the touch. I believe I have to thank a big colony of ladybirds for help in ridding me of this pest. Earwigs, too, have been more persistent than usual owing to the exceptionally dry weather, and it required much time and patience to keep them down. Aphides of sorts were busy and bred fast all the summer, but these are the least of troubles, as they can be stopped by using mild insecticides before they do much harm.

Late in the summer the "rust" appeared (for the first time here), and its spread has been marvellous in spite of treatment generally calculated to deal with any fungoid disease. Washing the leaves and removing every visible trace of spores have been of no avail, as another crop appeared almost immediately, fresh spores appearing round the old spots. I cannot say that the attack has done much harm as yet to the prospective flowers, but the leaves on affected plants die quickly, and this loss of foliage must tell for evil, especially where the rust has spread to the upper leaves. Undoubtedly I was, like many others, caught napping, and the enemy had time to spread to a good many plants before it was

noticed; then it was treated to the dose of flowers of sulphur usually applied to plants attacked by the ordinary form of mildew. This proved useless, and the time lost in waiting to see the effects helped to spread the disease till the greater part of the plants was badly touched. I never saw such a rapid development of fungoid disease on plants before; it seems only a few days from the time the spots are first seen till the brown spores ripen ready to fall on the lower leaves, the soil, or to be carried anywhere on the slightest contact. If the rust is calculated to do great harm, the outlook for growers is bleak, as it will take but a very short time to stock all existing collections, and those who are fortunate enough to possess a clean stock will be chary about making fresh importations, especially as the fungus cannot be detected during its resting period, in winter. I am now trying washing the plants with a solution of sulphide of potassium, and also with the solution suggested on p. 254 as a remedy, but as the fungus in its summer form appears to burst outwards from the leaf, I do not see that anything which will not destroy the cuticle of the leaf can prevent its development, and we shall probably have to wait until the spring before such remedies will be of use as preventives of the germination of resting spores on the host plant. Burning the plants wholesale has been suggested as a remedy, but few could afford to adopt such a drastic measure, and there would still be no guarantee of cleanliness in stock purchased to replace the losses. It has also been suggested that naturally-grown bush plants, which get less rich food than those grown for big blooms, are more or less exempt, but I do not find them so, as many of my bush plants are very badly stricken indeed, and they have had no artificial manuring whatever, simply soot water and occasional doses of ordinary manure water. The fungus appears to be well known as native to some of our weeds, and it probably spread to some nursery collection from a district where these weeds were affected, and as no plant is

more freely interchanged throughout the country than the Chrysanthemum, this would account for the rapidity with which it has spread. A. G. Hubbuck, W. G. Newitt, Pride of Madford, Thos. Wilkins, Mutual Friend, John Seward, W. Slogrove, Golden Gem, Etoile de Lyon, James Bidencope, Mrs. W. J. Godfrey, Purity, Modestum, Cecil Wray, and all members of the Empress family are some of the worst affected varieties here. This singling out of varieties is hardly fair, as their bad state may be only a circumstance, and others might have been just as bad. Even seedlings raised this year are attacked—some quite badly. It may be that certain varieties will be found less susceptible than others, for Khama, of which I grow many plants, and Reine d'Angleterre, with various others, are quite free.

Turning to the brighter aspect of the plants, I may say that they have grown strongly, and very many promise to be good even though the leaves of some of them have taken the rust. Among those which promise best are Vivand Morel, Charles Davis, Phoebus, Lady Randolph, Pride of Madford, John Lightfoot, Australian Gold, President Borel, W. H. Lincoln, Edwin Molyneux, Lady Esther Smith, M. Pankoucke, Etoile de Lyon, James Bidencope, Lago Maggiore, Matthew Hodgson, Golden Gate, Reine d'Angleterre, Eva Knowles, and Khama. The plants have been housed with very little show of the ordinary form of mildew; they are abnormally tall, some varieties, such as Edith Tabor, Mmc. Marius Ricoud, and a few others, reaching 10 feet in height, and others in proportion. This I do not mind, as, having lofty houses to fill, tall plants are no inconvenience, and a few extra tall ones make the blocks of plants less flat and more effective. Coarse flowers from early crown buds will be much in evidence this year, and with those who grow for show this is unavoidable, the tendency being to fix the dates of shows too early to allow such buds to be rubbed off in favour of second crowns, which give more shapely and better coloured flowers. In the

early days of *Chrysanthemum* shows the dates were later, and it used to be customary, even in the west of England, to have the shows after rather than before the middle of November, from that time to the end of the month being undoubtedly the proper season for the majority of *Chrysanthemums*. "H. S." (p. 289) speaks of a general curliness of show flowers this year, but this is not the case in this neighbourhood, and there has already been some talk of putting back dates. If this leads to fixing later dates for future years it will be one of the best things that could happen, as it would tend largely to eliminate the coarseness so generally prevalent and which is so obnoxious to many lovers of the *Chrysanthemum*. I think "H. S.'s" experience with *Mme. Carnot* will be pretty general this year, as I have seen but very few good buds and many that have turned black in the way described. I attribute it largely to early bud selection and not to insect attacks, for my plants, which were late-struck (in March or early April) and made late crown buds, are looking well and are past the dangerous stage.—J. C. TALLACK, *Livermere Park Gardens, Bury St. Edmunds*.

— Just now it would appear that many are the remedies for dealing with this so-called rust, which is assuredly a fungus of no light order. A curious point regarding it, so far as my knowledge of the disease is concerned, is that it appears on the under surface of the leaves in many kinds. I am not sure this is general or even characteristic of the plague, but if so it will render it far more difficult for any supposed remedies to reach it. Nor will the curling up so noticeable in some kinds assist the cultivator in this direction.—E. J.

GROWING PLANTS FOR EXHIBITION IN SMALL POTS.

A SYSTEM of culture which is becoming more common is propagating in the spring and flowering the plants on single stems in mostly 6-inch pots. Growers are beginning to appreciate the value of these late-struck plants for conservatory decoration and exhibition during October and November. The recent October show of the National *Chrysanthemum* Society showed the value of the system of culture advocated, the best and most meritorious collections containing plants treated in this way. The best flowers in the class for twenty-four Japanese blooms were grown in the manner stated above. The leading group in the competitive classes also contained flowers of exceptional beauty, and, as compared with the productions usually displayed a month later, the blooms were quite equal in point of excellence. The plants were dwarf and covered with healthy-looking green foliage down to the pots. The group from Mr. H. J. Jones was noticeable for the short plants arranged in circular mounds in the front, and many of the best blooms in this unique display were developed on plants flowering on single stems in 6-inch pots. A visit to the leading specialists will reveal the fact that the practice is extending. The orthodox method of growing the *Chrysanthemum* for years has been to insert the cuttings at any time between the end of November and the same period in the following January, suiting the time for this operation according to the earliness or lateness of the different varieties, commencing first with late sorts and finishing up with the semi-early or October-flowering kinds. To those with limited accommodation this has answered admirably, as the old stools have been thrown on the rubbish heap after the necessary supply of cuttings has been secured. The old stools, if they can be kept till the spring, should bristle with numerous growths of a sturdy character and of a kind that will root readily enough in early spring.

The best lot of plants seen this autumn was from cuttings inserted between mid-February and mid-March, and the flowers from these for an

October display develop to time beautifully. When the cuttings were ready shallow boxes were used, standing these on a cool bottom, the temperature of the structure being maintained at from 40° to 45°. Under such favourable conditions the cuttings rooted readily, and before the roots began to work into the soil too freely they were potted up into small, deep 3 inch pots. They were then replaced in the same greenhouse, and when it was seen they had got sufficiently established moved to a cold frame, which was kept close for a day or two. As soon as they were ready the plants were shifted into pots 6 inches in diameter. A collection of some few hundreds of plants has given some very remarkable results. When once the buds were secured it was a simple matter to build them up satisfactorily, and owing to the exceedingly hot and trying weather during the period of bud-formation and selection, a gentle dewing overhead with a fine-rosed can in the late afternoon occasionally saved many that might otherwise have been lost. A few sorts failed to open so kindly as could be desired, but the majority answering so well to this method of treatment should be an inducement to others to follow on the same lines.

For a November display later propagation is desirable, commencing with the late sorts about the middle of March and continuing on until the beginning of May to suit the earlier and more easily grown kinds. D. B. CRANE.

NOTES AND QUESTIONS.

Chrysanthemum Rayonnante.—For October flowering this Japanese variety should be in demand. The petals are very long and tubular and of fine substance, the colour a peculiar shade of pale salmon-pink, deepening in the centre, and not unlike that of the once popular *Lilian Bird*. The height is about 5½ feet. It produces its blossoms on first crown buds from a natural break at this season.

Chrysanthemum M. Fatzer.—This is a promising continental novelty, and may be had in bloom during October and November, according to date of bud selection. The colour is a rich canary-yellow, with a deeper shade in the centre and a pale golden reverse, the petals of medium width, slightly twisted and incurved, and building up a grand exhibition flower. The plant attains a height of about 4 feet.—D. B. C.

Chrysanthemum Crimson Mile. Marie Masse.—This is a crimson sport from *Mlle. Marie Masse*, and, flowering during the months of September and October, is a valuable addition. It would, perhaps, be better to describe the flowers as a light bronzy crimson, and very early blooms would show a goodly proportion of rich golden yellow, freely suffused with a very pleasing light crimson. The petals are also bright golden on the reverse.—C.

Chrysanthemum M. Aug. de Lacvivier.—This is doing extremely well this season, the later buds producing even handsomer flowers than those secured a week or a fortnight earlier. The colour, as represented by the later buds, is a beautiful rich salmon-red, with a pale golden reverse to the broad petals. The earlier flowers are not nearly so rich in colour. Plants topped in mid-April give first crown buds about the first week in August, these being now fully expanded. The height is about 3 feet.—C. A. H.

A GARDEN IDYLL.

THERE are many beautiful gardens along the deep sandy shores of Dublin Bay, some nestling on sunny hillsides, others in sheltered valleys that stretch along the foothills at the base of the mountains, and some even nestle among the warm rocks laved by the sea. From the shores at Dalkey and Ballybraek to the wooded pleasure-land at St. Anne's there are gardens many and beautiful, but they may be found stretching even further to Raheny, Sutton and Howth, and back again inland. There is a zone of them from Rush and Lusk to Malahide and St. Dolough's, with its quaint old stone-roofed church, its anchorite's cell, and its exquisite little baptistry in an adjoining

meadow. Go where you will along the shores of the bay, or if you dip inland a mile or so you come across delightful country houses, old and new, and gardens of all sorts and conditions full of beauty and rich in vegetation. Although I have lived in and explored the district for well-nigh twenty years, I am still continually making discoveries in the magic zone of littoral that lies around the great horseshoe-shaped bay. From the old Cherry orchard of Killencarrig (see *THE GARDEN*, May 8, 1897) to the giant red and golden-fruited Yew trees at Clontarf there is much to see and admire; rich and rare are the flowers from many lands that find a congenial home in these sunny gardens, and you can see and remember the Mulberry trees and the Hex at Mount Merrion, and run on through a whole catalogue of rare trees and shrubs until you come to the famous Iris borders beside the gentle concave grass paths at Dordun, the Hollies and Cordylines in the College garden, the original golden-leaved Yew and Addison's Walk at Glasnevin, the great Beech hedges, and the Rhododendrons that nestle amid rocks and white Thorn, and the tasselled Larches at Howth. To see these last in showery April or in smiling May is like a dream to a lover of gardens, and one does not quite know what most to admire there in early summer—whether 'tis the glow of crimson and white and lilac of the Rhododendrons or the gnarled old white Thorn trees wreathed and swaddled in Honeysuckle or Woodbine, in some cases 30 feet or 40 feet high. Just now, however, when Lime, Beech, and Chestnut are putting on their russet and golden tints, and when the golden Ivy on the old walls is nearly covered with the rich red leafage of the Virginian Creeper, when the last and best of Roses glint here and there, and the rosy Apples and great brown Pears hang in clusters on the bending boughs, it is a pleasant surprise to find yet one more delightful old house and garden I never saw before.

We hear much of Constable's or Gainsborough's country, or of Shakespeare's land beside the Avon, but how rarely are we told of these fertile garden spots in Ireland, enriched as they are with "memories of the dead" and the blood and bones of both swarthy Celt and fair-haired Dane. How can one picture to oneself to-day the fateful morning of the great battle of Clontarf in 1014, when Aulaf Sitric, king of the Danes in Dublin, was conquered by Brian Boru on this same sunny bit of shoreland which stretches from Dublin to Howth. Every foot of ground here is full of interest, and the funereal mounds of dead heroes now alone remain to show us how bitter the struggle must really and truly have been. Where stress and storm of battle raged there are now green or furrowed fields and gardens that yield to none in their wealth and beauty of vegetation. All the shoreland is indeed in itself a garden of wild flowers from early spring, when Gorse and Broom are succeeded by vernal Squills and hedge or sand Roses, until the dwarf autumnal Furze and the heather of the great headland, last foothold of the pirate Danes, brings us to the fall of the year.

Between the magnificent gardens at St. Anne's and the old sequestered gardens of Howth Castle, with their Lavender and Rosemary and great Gloire de Dijon Roses, there lies the village of Raheny, and here is a veritable garden of quite an idyllic kind. It is modestly screened from the road, but even the casual passer-by must know sweetness and light are within its evergreen enclosure, for the fragrance of Mignonette and Lavender, and of Stocks and Night-scented Tobacco, of Roses

and of Virgin's Bower Clematis float out on the balmy evening air. Here are Myrtles, fresh and fair and 10 feet high, glossy green and flowery under the overhanging thatched eaves, where the wrens build, and in the inner garden sweet-scented Verbenas, much taller, with many a scented flowering spray. It is one of the sheltered and sunny gardens that birds and bees alike love. It has no nightingales, like those gardens beside the Thames, but here at any rate the thrushes and blackbirds sing their earliest and sweetest songs, for it is a fruity paradise to them, and truly a garden that they and the poets alike are said to love.

The Peaches are gone, but the Grapes of sloe-like blackness and the amber Muscats dangle in rich clusters among the turning leaves in the old vineries, while on the border outside a great French soup Gourd (*Cucurbita maxima*), the "courgeron" of the French housewife, is displaying its great rounded fruits along its trailing leafy stems or vines. All around one is sunshine, and ceaseless the hum of the bees and flies. The wood pigeons coo softly in the tall trees quite near to the house, and one of the oldest and most faithful of the pensioned servitors of the family, a shaggy white Iceland pony, is browsing contentedly in an adjoining paddock, with one eye on the garden door, whence, as he well knows, the most succulent and toothsome Carrots or other delicacy come to him at least once or twice a day. There are the old flue-heated greenhouses which shelter many an old-time sweet-scented Pelargonium, and the old white, lemon, yellow, pink, and crimson Cacti that our grandmothers loved to carry indoors and set in the fine old oriental Chinese bowls when in bloom.

The house itself is a combination of a modern dwelling tastefully added to an older thatched cottage, and the union is veiled by a curtain of Clematis montana and Virginian Creeper, the latter so highly coloured as to remind one of the rugs hung out in Venice at festival time. The very name of the place itself is redolent of a garden, but it need not be told; sufficient is it to say that the place is a beautiful and satisfying reality, and that it stands in what I often think of as an idyllic little bit of country Dublin.

F. W. BURRIDGE.

ORCHARD AND FRUIT GARDEN.

MANAGEMENT OF EARLY PEACH HOUSES.

THERE was more early fruit-forcing twenty years ago than there is now, and the old gardeners were noted for their success in producing fine ripe Peaches in May. The extra early varieties, such as Waterloo and Amsden June, were not then in commerce, and they had to depend on such old standard sorts as Bellegarde, Noblesse, and Stirling Castle. Even now one tree of an early American variety is enough in an early Peach house, as most of them are not to be depended on, being such notorious bud-casters and the fruit not equal in flavour to many of the older, though slightly later-ripening varieties. Amsden June I consider to be by far the most certain bearer of the first early section; indeed, with me it never shed its buds when gently forced, and was always of good flavour if gathered in time and eaten soon after. A lean-to structure with a fair amount of wood in the roof is what I prefer for early Peach forcing. The modern-built houses with roofs composed almost entirely of glass, and built with a sharp pitch,

often become so hot from sun-heat even early in the year, when only a limited amount of air can be given, that harm ensues, and later on, in the case of houses with fixed lights, the temperature becomes so high that premature ripening of the wood and consequent bud-dropping follow. Formerly the roof-lights were removed entirely when the crop was gathered, this exposure to air and every shower of rain helping in a great measure to produce that bronzeness of wood and plumpness of bud which fit the trees for the strain of early forcing. I prefer both an inside and outside border, the latter raised so as to come on a level with the inside one, the soil being kept intact by low walls. It may be asked, Why have inside borders for early Peach houses? The answer is, Such borders, if covered with a foot or 2 feet of dry leaves and thatched with straw at the end of October to keep in the latent warmth of summer, will, when uncovered in April and acted on by the sun's rays, be quite as warm as the inside border, to say nothing of the beneficial and maturing influence of fresh air upon the roots. Trees growing in such borders do not hold their foliage late even in wet summers, but shed it early, thereby securing a long rest. In pricking the border over when uncovered in spring, a multitude of fibrous roots will generally be found near the surface. Of course, a little more labour is entailed in watering elevated borders, especially in hot summers, but they will repay it. I think many failures in early Peach forcing are attributable to the thoughtless practice of syringing the trees in the afternoon on cold, wet days. They remain wet through the night, and mischief follows. For ripening in May and the early part of June, Early York, Early Grosse Mignonne, Stirling Castle, Bellegarde, and, where room can be spared, a tree of the old Noblesse, which, if only bearing half a crop, pays for its space, it being, I think, universally admitted to be the finest flavoured Peach in cultivation. JOHN CRAWFORD.

Passiflora edulis.—From the inquiries that are being made and information solicited as to the cultivation of the above, it is evident more interest is evinced in this delicious fruit now than hitherto. I have of late received fruits of the true *P. edulis* from various sources, and have a few still growing here, but as the small size was in my case an objection, raising seedlings from selected fruits was resorted to, and as the young plants fruited rigid selections were made and the process repeated. At present I think my selected variety is a decided improvement in the matter of size, and to say the least, equally as delicious as the type.—J. ROBERTS, *The Gardens, Tan-y-bwlch*.

Pear Swan's Egg.—How is it we so seldom see any reference to this old Pear? Surely it cannot be because it is considered a worthless variety? Its extremely hardy constitution renders it suitable for exposed situations, and I consider no orchard is complete that does not contain at least one tree. It is an extra good grower, assumes naturally a handsome pyramidal form, the dense growth and foliage going a good way towards protecting the bloom in spring. It is a regular and heavy bearer and the fruit is very sweet and juicy. Swan's Egg is one of the best orchard market Pears, keeping sound a fair time after ripening, which it does at the beginning of October. I well remember when a boy filling my pockets from a very large tall tree, from which many bushels of fruit were annually gathered.—J. CRAWFORD.

Pear Beurre de l'Assomption.—I do not know what the experience of other gardeners with this Pear may have been, but with me it proved most unsatisfactory. It is a strong grower, and after a few years bears freely, but its fault is

that the fruit decays so quickly. I had a fine tree of it on a west wall, and used to pack the large fruits and send them to Scotland, gathering them before they readily left the spur, and I was invariably informed that soon after they reached their destination they were useless. Finally, I cut the horizontal branches back and grafted them with Olivier de Serres, which seemed quite at home, bearing a few fruits the second year from grafting. I do not wonder at gardeners rooting out or re-grafting these extra treacherous varieties with better keeping sorts, as when the trees bear a full crop all the fruit cannot be used in a given time and much of it is wasted.—N.

Morello Cherries.—Visitors to the Shrewsbury and Crystal Palace shows in August and September often see wonderfully fine dishes of Morello Cherries in the various collections of fruit. Those usually found on Cherry walls cannot compare with them. The trees, however, from which these monstrous fruits are gathered receive special culture. As a rule Morellos are trained too thickly, the roots also receiving little attention in the way of mulching and manurial waterings, black aphids often injuring the new growth. When once a healthy young tree gets established and commences to bear fruit it will take a liberal amount of feeding, liquid manure being poured on to a thick mulch of short litter, this being raised at the edges so as to prevent the liquid from escaping. The trees must be netted in good time, as birds will take the Cherries as soon as other fruit is gone.—J. C.

FAILURE OF FORCED FIGS.

THE season has been so favourable to Fig culture under glass, that there may have been fewer failures than usual, but I have noticed there have been such by inquiries in THE GARDEN. Failures are annoying, as they usually occur just as the Figs are taking on the last swelling. With trees planted out there is more trouble with the first crop than the second. This is readily explained. The Fig, being so gross if allowed free play, needs careful management to mature the first crop and at the same time build up wood for the following one. If excess of top growth is allowed, this is one of the principal causes of failure. My remarks apply to old trees in a restricted border with the roots under command. My idea is that dropping of fruit when nearly full grown must in a great measure be attributed to too much vigour in the trees. Fig trees do not always bear a heavy first crop. They have, so to speak, too little to do, and unless hard stopping is practised, the fruits drop badly. With stress of work I have seen trees left alone a few days. It takes time to remedy this, as if the lateral growth above swelling fruits has got the lead, the Figs will soon cease to swell, as the wood above absorbs all the sap and shrivelling of the fruit follows. With fruits at this stage there must be severe stopping. It may be asked, Why does this not take place with the second crop? One reason is that there is a greater quantity of fruit; the sap is more evenly distributed and the wood growth is not so strong in consequence. I may be wrong in my ideas as to fruit-dropping, but such is my experience, and I force Figs largely both in pots and planted out.

Excess of moisture overhead when the fruits are finally swelling is one cause of failure, this accounting for the fruits spotting, more especially in the case of the first crop. This is doubtless owing to want of air, the leaf of the Fig retaining moisture longer than a smooth leaf if it is given freely. The house, too, may be kept too close at this stage, and with Figs ripening, more air is a necessity. At times it is not given early enough, the consequence being the fruits decay. With excess of moisture must also be included too much heat and not enough ventilation. Inattention to the latter will cause dropping, especially when the two are combined. It is always well when the fruits are approaching maturity to lower the temperature at night and maintain a drier atmosphere both

during the night and in the day, this improving the flavour of the Figs. My worst trees as regards dropping or spotting are those at the middle of the house. Those on a back wall with more ventilation never suffer.

I have not referred to pot trees, but the evil is nearly as bad if the trees are of any size. Trees grown in pots during the late summer and not forced never lose a fruit. Such trees get more air and a less steamy atmosphere. Less fire-heat is employed, and they get more warmth from the sun. Some kinds grown in pots, such as St. John and Pingo de Mel, do not fail like the Brown Turkey, one of the worst if allowed free growth and given too humid an atmosphere when the fruit is finishing. I have not included Negro Largo in my remarks, as this I do not force hard. In fact, if one does, the crop is not heavy enough: far better bring on quietly, then it finishes well, and for late forcing it is very good and at that period gives no trouble. This remark applies to some other late kinds, such as Signora Bianca, a fine late red-fleshed fruit. Nebian needs the same treatment as Negro Largo. The smaller Figs, such as the Ischias, both Black and White, rarely fail if forced. These produce a great quantity of fruit, and will if grown liberally give three crops in one year. Three crops should, however, never be taken, as this treatment will affect the earliest crop the next season. I think one of the worst failures is caused by neglect of stopping. G. WYTHES.

Peach A Bec.—Fifteen years ago this Peach seemed to rush to the front and bid fair to become a leading variety, especially for forcing. Now, however, one seldom hears or reads of it. So far as flavour is concerned it has few equals, being similar in that respect to the old Noblesse. It used to be a great favourite with Mr. Coleman, when gardener at Easton Castle. Perhaps it is rather tender and requires skilful cultivation. One of our largest nurserymen who once had a stock of it does not now catalogue it. Perhaps some reader of THE GARDEN will give his experience of A Bec.—NORWICH.

Pine-apple Moscow Queen.—There are two varieties of the Queen Pine-apple, that under the name of Ripley Queen being the better known and more generally cultivated. My favourite, however, is the Moscow Queen, a larger pipped, heavier sort than the Ripley. They are about on a par as regards flavour, but the plants of the Moscow are hardier and more easily grown. The habit of growth is stiff and the plants do not, as a rule, attain a great height. An old Pine grower once said to me, "If you get a fairly good plant of Moscow Queen you are sure of a good weight of fruit." It is also far less liable to develop large, ungainly crowns. Some years ago, when gardener in Worcestershire, I had a good stock of Moscow Queen, but have only seen a few in one collection since. The leaves are very dark in colour, and on well-grown plants carry a dense bloom.—B. S. N.

Colour in Apples.—Those who hold the idea that sunlight and warmth are only needed to put colour on the cheeks of Apples must have had a rude awakening on seeing the deficiency of colour throughout the major part of the Apple exhibits at the Crystal Palace fruit show. Last year colour was a strong point; now we find many varieties that are usually well coloured green in the ground and dull in the flush. Possibly the alarming extent to which blackbirds and tits have raided orchards in search of moist food during the abnormal drought may be accountable for some of this deficiency, as it has been impossible to keep them away from the earliest and best coloured fruits except by rigorous netting, which becomes impossible when dealing with orchard trees. The Apples from Kent were for once very little better off for colour than those from Essex, Suffolk, Norfolk and other more northern counties where the drought has been severe. Most of the highly-coloured fruit came from the western counties, where a moister atmosphere has prevailed and

where there has been more wind. My experience is that Apples colour best in years when light showers and stiff breezes, accompanied by a fair amount of sunshine, are fairly prevalent during the late summer months, and I think the experience of this season is quite sufficient to prove it.—J. C. TALLACK.

MISTAKES IN ORCHARD TREE PLANTING.

So much has been written of late regarding the selection of ground and its preparation for an orchard, that a few notes on mistakes made in this matter may not be out of place. It is a simple matter to say what kind of soil and situation should be selected for hardy fruit culture, but it is, I fear, a rare thing to find the right formation in the right place. In fact, I believe it more frequently occurs that the question of disposing of certain pieces of land more often leads to the planting of orchards than would otherwise be the case. If such land happens to be of the right sort, and will respond to the kind of cultivation adopted, all is well, but should its composition entail careful consideration to securing the best conditions for hardy fruit-tree growth, there is just a possibility of a mistake being made in its preparation. Writers, as a rule, select a loam of good depth, and rightly, too, for orchard trees, and this they recommend cultivating deeply. If naturally well drained and rich in readily soluble constituents of plant food, trenching is just the thing for it. These conditions, however, will not obtain in one out of a hundred of the plots given up to fruit culture, yet trenching, be it sand or clay, deep or shallow, is carried out with the same persistency by some as if it were mellow loam. Recently I came across a small, newly-formed orchard, where the owner did not consider the initial expense, provided healthy fruitful trees were secured. The soil was of a sandy nature, 3 feet deep, with a substratum of sandy rock. By a regular system of top-dressing with manure, the surface 9 inches was in a very fertile condition, but the lower portion, as will readily be imagined, was rather poor. By way of preparing this land for orchard trees, the person responsible for the work had it trenched to its full depth. The rich surface soil was placed in the bottom, and the barren sand brought to the top. In due course the trees were planted and the space occupied by their roots heavily mulched with manure. As will naturally be concluded, the plants existed, but the growth was very poor. The mistake made in putting the fertile layer of soil so deep in this case was twofold. It was beyond the reach of the plants' roots for immediate requirements, and it would eventually draw them down to a cold, ungenial position. Under such unfavourable conditions the trees could not avoid getting into a bad state of health. A few practical lessons of this kind would go farther in convincing cultivators of the errors of their ways than pages of sound instructions in the gardening press. Now the above mistake has been discovered, the best means are being taken to bring up the barren surface soil to its maximum of fertility by heavily dressing it with liquid and solid manures, bone-meal, and sulphate of potash during the winter months.

Another example of an error in judgment in connection with the preparation of sites for fruit trees on heavy soil came under my notice some time ago. About 9 inches of the surface of this were fairly good heavy loam, and below this were layers of gravel and clay. In this case only 5 feet square was trenched 2½ feet deep for each tree, but the same mistake was made in this instance as in the foregoing in placing the surface portion in the bottom and the bottom on the top. As this was done early in autumn and the clay and gravel mixed with well-decomposed organic matter from the refuse heap and ridged, the winter's frosts, rains, and atmosphere ameliorated the conditions of the mass in favour of the plants' requirements. The trees were planted in spring and did fairly well for a few years, but when the

roots had permeated the soil in this limited space an unsatisfactory state of things manifested itself. In order to find out the cause of crippled growth, some of the trees were examined at their roots, when it was found that the major portion of these had gone down into the bottom layer, used all the food it contained, and were seeking for more in the walls of clay and gravel by which they were surrounded at that depth. Had all the ground been treated in the same manner as the 5 feet square for each tree, even although it was a mistake to bury the best soil so deep, in all probability the orchard would have become a fairly satisfactory one. At this stage there was no reason why the whole should not be trenched, so far as the plants were concerned, but men and money were scarce, and a course of surface feeding was decided upon instead, to try to retrieve the ground lost.

Both of these orchards were laid down in grass, so that there would be no digging to destroy the surface roots. The question of securing a mat of feeders near the surface seems to be generally under-estimated, even although frequently pointed out. Yet the most casual observer cannot fail to see the difference in the health and fruitfulness of trees with the majority of their roots within the first 15 inches of the surface soil, and those whose roots are in a cold lower layer. Mistakes like these referred to may be exceptions, but by pointing them out, others of a similar nature may be avoided and more rational methods obtain.

J. RIDDELL.

Little-grown Apples.—Doubtless with the praiseworthy desire to popularise what may be very excellent Apples, the single dish classes of the dessert section at the recent Crystal Palace fruit show included Allen's Everlasting, not at all an attractive name; D'Arcy Spice, Duke of Devon-hire, Egremont Russet, James Grieve, and Lord Hindlip. Of the last not a dish was shown, and there were very few of the former varieties. Evidently they are little grown, or produce such poor samples that few care to exhibit them.—A. D.

Nectarine Humboldt.—"E. M.'s" note (p. 234) on that fine, richly-flavoured Nectarine Pine-apple reminds me of that other fine yellow-fleshed variety Humboldt, which, by the way, is a seedling from Pine-apple. The fruit grows even larger than Pine-apple, though perhaps not quite so rich in flavour. The tree is a good grower and very fair cropper. I once put in some buds of Humboldt on a tree of Lord Napier, and as the young shoots grew I cut away some of the wood of Lord Napier, giving Humboldt a share of the trellis. It did wonderfully well, fruiting regularly and ripening quite a fortnight later than Lord Napier. In gardens where glass accommodation is limited this budding is an advantage, as a greater variety and also a longer succession of fruit can be secured, and some sorts seem to do better thus treated. Mr. McIndoe has done a good deal of budding one sort on to another at Hutton Hall at different times with much success. Princess of Wales Peach budded on Violette Hâtive did well with me, the fruit being very fine.—N.

Plum Gordon Castle.—Very rarely is any reference made to this Plum, and more seldom is it seen, at any rate in the west of England. I cannot remember having met with it anywhere except in these gardens, and it is represented here only by one cordon tree, which furnishes one of the piers of the garden wall. Dr. Hogg, in the "Fruit Manual," describes it as large and obovate; skin greenish yellow, flesh rather firm, sweet, and with an excellent flavour. He also says it is useful for growing in the north and late situations. This may explain somewhat its absence from southern districts. With me it assumes a different colour from that given by the late Dr. Hogg, having quite a rosy flush when exposed to the sun; indeed, this is so marked that at a distance it would not be taken for a Plum at all. It comes into use here in September, and makes a very striking dish when placed on the table. It is rather shy bearing as a cordon; whether it would be more free as a

fan-trained tree I cannot say, but probably it would, many kinds of Plum not bearing freely as cordons. It is, I think, the most distinct of all Plums, larger than Washington, and the rosy flush known to this kind in its true form is intensified in the case of Gordon Castle.—W. S., *Road Ashton, Wilts.*

Plums.—In a year when Plums have not been quite at their best I must note the good cropping qualities of Oullin's Golden and Transparent Gages and Golden Drop in dessert varieties, and Early Prolific, Czar, Diamond, Pond's Seedling, and Imperiale de Milan in cooking sorts. So far as the latter are concerned, from the first pickings of Early Prolific in the middle of July I have been gathering every other day for the kitchen until the present date (September 24) besides the supplies for preserving, and Imperiale de Milan and Coe's Late Red will carry us on until nearly the middle of October, a length of season that illustrates the great value of the Plum where it can be planted rather largely in variety. The damage usually caused by birds has been obviated this year by netting all the trees. Cheap wide mesh netting answers the purpose, as blackbirds are responsible for the mischief. On a north-east wall Diamond and Imperiale de Milan are this year very good.—E. BURRELL.

PLANTING STRAWBERRIES ON DRY GROUND.

ONE of the chief points to be observed in forming new Strawberry beds is providing sufficient root moisture, so as to give the young plants a good start. Not infrequently a deal of time and trouble is given to preparing the runners, these being eventually spoiled by being planted in loose, dry soil, perhaps on a plot from whence Cauliflowers or Potatoes have just been cleared. Water may be given artificially, but more often than not growth under such conditions is slow and unsatisfactory, and although the plants may have been quite free from insects when put out, red spider often gets a hold and forms quite a colony before winter. If this should be mild the pest lives on, ready to renew its destructive work as soon as warm spring weather appears. When such plots have to be dealt with, and at times there is no help for it, the only safe way is to well soak them with water, allow the surface to remain for a day, then firm well by treading twice over, and finally water well again. This may seem a lot of trouble, but it is really a saving of labour in the end, as if each plant is firmly embedded, watered home, and mulched round with a little old Mushroom manure or rough leaf-mould, water will in all probability not be wanted again before rain comes; whereas when planting is carried out in dry soil, one may be always watering, and yet the plants seem little the better for it. There is no need to mulch the whole surface of the ground at planting time; the distance of a foot round each plant is sufficient. When Strawberries are planted between rows of spring-sown Onions there is never this root moisture difficulty, as the ground being firm retains the moisture and is altogether far more suitable for the roots than ground which has been robbed of every drain of moisture by impoverishing summer crops. We sometimes read of gardeners clearing off a crop of Potatoes, Peas, or Cauliflowers, loosening and levelling the surface, and planting Strawberries at once, but when we consider the impoverishing nature of these crops it is evident that most of the virtue must have been taken out of the manure that was dug in in spring, and that the Strawberries will have to go short. Even supposing the plot to be remanured, manure fresh from the cow or pig-yard is not the best medium for promoting the growth of such foliage and crowns as will ripen well before winter. I am quite sure that if gardeners would plant on Onion plots which were well manured early in the year, sowing the Onion seed in lines 2 feet or 2½ feet apart, they would be satisfied with the crops of both. It is always advisable, whether spider is visible

or not, to syringe young Strawberry plants with sulphur water previous to planting.

J. CRAWFORD.

FERNS.

FERNS FOR COVERING WALLS.

THERE are few positions where Ferns are seen to better advantage than when used as a covering for a wall in a shady position. There are various methods of doing this. Cork pockets may be used, or earthenware pots made for hanging against walls answer the purpose. Perhaps the best way is to cover the whole surface of the wall with rough peat and other soil, fixing it up with wire netting. Only quite small plants can be used to start with when this method is adopted, but with ordinary care they soon get established. In making a selection of suitable Ferns for the purpose, the space available is the first thing to consider, and in planting care should be taken that the small and choicer sorts should not be placed where they will get smothered by the more vigorous-growing sorts. Among the best for the purpose are the Adiantums of the *Capillus-Veneris* type. *Davallias*, *Nephrolepises* and some of the *Polypodiums* may be recommended. There are also others, where plenty of space is available. I may mention *Stenochlæna scandens*, which spreads rapidly even if grown in pots, and given a good start it will cling like Ivy, and the bright green pinnate fronds are very effective. *Pteris moluccana* does not spread so rapidly, but for an elevated position on a wall it is a very fine Fern. Of Adiantums there are few better than the old form of *Capillus-Veneris*. The varieties *imbricatum* (which has very broad pinnules), *grande* and *magnificum* may be recommended. *A. assimile* is one of the most rapid growing, and where the rhizomes can spread freely they soon cover a good space. *A. Moorei* (*amabile*) is also worthy of note, but, unfortunately, it is deciduous, and this is rather against it where a good appearance is required to be kept up throughout the year. Most of the *Davallias* will do well, as they do not require so much root-room as most Ferns. The varieties of the *dissecta* type are perhaps the best, as the rhizomes spread rapidly. *D. Mariesi*, though deciduous, is a desirable variety. It remains dormant but a very short time, and the new fronds will generally start before the old ones are off. *D. Tyermanni* has rather small fronds, but the silvery grey rhizomes are very conspicuous. Where space will admit, *Davallias* should be freely used, as they give a variety of shades and always have a bright fresh appearance. Next to these the *Nephrolepises* are the most useful for walls. *N. pectinata* is the smallest growing and one of the best, though not quite so hardy as *N. philippinensis*, which is more erect in growth and of a deeper green. *N. exaltata*, now so extensively grown for market, is one of the best where plenty of room can be given. The crested varieties of *N. davallioides* are very pretty, but are inclined to get too dense for walls. All of the *Nephrolepises* require a little looking to and thinning out as the young plants spring up. *Goniophlebium subauriculatum* requires a warm position, and will make drooping fronds fully 6 feet long. The dark bronzy fronds of *G. appendiculatum* give a variety in colour. Of *Polypodiums* there are a number suitable for the purpose. The small-fronded *P. pustulatum* spreads freely and forms a dense mass of deep green. *P. glaucum* (*Goniophlebium*), which has small ovate fronds of a pale glaucous green, is very useful. This must not be confused with *Phle-*

bodium glaucum, which more resembles *P. aureum*, but has smaller and more drooping fronds, and is also a good wall Fern. The *Platyceeriums* never do better than when growing against a moist wall. Although they will grow on a piece of wood, they do better where they can root into some rough peat, but should be placed where they do not get too much moisture. A. H.

NOTES OF THE WEEK.

Peaches in Devon.—We have received a photograph of a tree of the Diamond Peach in Captain Hody's garden at Pomeroy, Honiton, Devon, bearing 306 fine fruits; also photographs of *Noblesse* and other kinds, which clearly show that the Peach does admirably in that district.

Chrysanthemum Queen of Earlies.—At the Aquarium last week were some notable examples of this fine early white, that is, so far as the heads of bloom were concerned, for the stems, which were cut of an extraordinary length, were quite leafless—a possible result of the dreaded fungus rust.

Ixora Dixiana is one of the most effective of the family, the rich dark red-orange flowers being produced in great numbers. The size of the heads of bloom and the colour thereof are not the only points of merit, for to these must be added the great freedom of flowering. The corymbs are very compact and well formed.

Hæmanthus coccineus.—This old and showy kind is very conspicuous when grown in large runs that accommodate a number of its huge bulbs. This was the case in a large example flowering at Kew the other day, the specimen in question containing about eighteen of the rich scarlet heads that make a fine display.

Verbena Ellen Willmott.—This pretty kind should cease more materially assist to develop the taste for the *Verbena*, seeing it is one of the showiest and most profusely flowered that has appeared for a long time. A nice lot of its flowers at the last meeting of the Royal Horticultural Society proved that it is a capital late-blooming sort.

Chrysanthemum de la Guille.—Should this prove a reliably hardy sort, its colour should render it among the most popular. The plant is very free-flowering, the colour a soft chrome, with a suspicion of light orange in the tips of the florets. The flowers are also borne on freely-branched stems, and the whole plant is not more than 2 feet high.

Aster Mary Crum.—This white-flowered *Michaelmas Daisy* is highly thought of by many. I do not consider it equal to either *John Wood* or *Madonna*, but it appears to be of taller habit here than either of these fine varieties. The flowers, too, are smaller and more starry, but they are of a good colour and very suitable for cutting.—S. ARNOTT.

Aster seedling from Arcturus.—Last year the Rev. C. Wolley-Dod sent me a seedling *Michaelmas Daisy* from *A. Arcturus*. It did not attain its full character until this year, and as it is growing beside the parent, one can now see that it is superior in size and colour. *A. Arcturus* is deservedly a favourite from its deep lilac flowers and its generally effective appearance.—S. ARNOTT.

Crinum fimbriatum.—Quite recently this handsome species was noted in flower at Kew. The flowering example had produced a stout and vigorous scape 2 feet high and an umbel of ten or twelve flowers, the latter of good substance and coloured externally to a large degree with reddish purple, the inner portion of the segments being white and lined or striped with a similar reddish purple hue.

Cuphea eminens.—This species with its shrub-like stems is quite distinct from the ordinary bedding kind, which is of prostrate habit and short-lived. The above plant attains fully 3 feet high, the stems somewhat woody, and in the upper parts freely covered with tubular-shaped blossoms of an orange and yellow shade. The plant is quite distinct among many greenhouse subjects now in flower.

Lobelia cardinalis Prince Arthur.—In the well-known kind *Queen Victoria* it would appear we had all that was necessary for brilliant and striking effect in the garden among these flowers, yet the above undoubtedly goes one better in that it is of a more intensely vermilion-scarlet shade. A bed or large

group of such an one would have a remarkable effect. Coming, too, in the waning summer months, its uses may indeed be manifold.

Kniphofia grandis.—This certainly is, as implied by the specific name here given, one of the finest of the Flame Flowers. Its beauty, however, is not seen until the plants have become established, and the strong massive spikes tower aloft in a manner supremely noble and effective. In the distance, too, its massive spikes of deeply-coloured flowers, as much as its noble growth and general vigour, impress all who see it for the first time.

— I have a large bed of this with great numbers of spikes like those sent, with many others just showing, and with moderate weather they will continue to flower up to Christmas. I found it growing at Tresco, Isles of Scilly, but the name was not known there. It is a constant bloomer, very strong grower, and, I think, one of the best of the whole family.—W.M. SANGWIN, *Trelissick, Truro.*

Nicotiana affinis.—While the early frost has quite swept away many tender flowering plants, this provides quite a display each evening, which is quite apart from the wholesale fragrance that it sheds around. Happily, the plant is not tender; indeed, in some gardens it proves quite a true herbaceous plant, and enduring the winter, springs again from the underground rootstock. No vestige of life is apparent from the surface, and, where possible, the plants should be allowed to remain undisturbed, as the older plants flower much earlier the second year.

Aster turbinellus.—Those who require a beautiful and pleasing Michaelmas Daisy for pots cannot do better than grow this charming kind. In point of habit it is perhaps one of the most elegant of all the race, and when seen in the form of large bushes is exquisite. What provides such an elegance and beauty of form in this kind is the rather exceptional length of the peduncles bearing the prettily coloured and solitary flower-heads. It must be seen fully grown if we would get all its beauty. The ray florets are of a violet shade, tipped rose, and the whole plant is very graceful.

Ixora coccinea lutea.—Such is the name of a very distinct and welcome kind among these well-known stove-flowering shrubs. The colour of the flowers is a pleasing and decided tone of rich chrome-yellow, and therefore very striking among this class of plants. It evidently bears a strong likeness to *I. coccinea*, otherwise so exceptional a plant at first sight would appear to merit specific distinction. Small bushes of this handsome form, which is a native of Ceylon, were recently in flower at Kew.

Colchicum autumnale album.—The double white Colchicum has been very fine this season, and the flowers appear to be rather larger than usual. It increases rather slowly, and this perhaps accounts largely for the high price at which the corms are still sold. Like other Meadow Saffrons, it requires the support of other plants to keep its blooms upright, but I fancy it lasts longer in bloom if the flowers lie prostrate on a carpet of Saxifrage or Arenaria. I saw a rather pretty effect the other day of Meadow Saffrons growing among the leaves of *Iris cristata*.—S. ARNOTT.

Oenothera macrocarpa.—This trailing Evening Primrose still gives us a few of its fine yellow blooms. It is said to be sweet-scented, but I cannot detect the odour. It may, however, be present earlier in the season than at this time—the middle of October. Very pretty, however, are the large flat cups of pale but bright gold, below which are the red and creamy-white calyces, which look so attractive in themselves. At this season this Evening Primrose is not so fleeting in its beauty as earlier in the year, the blooms remaining in perfection for a few days at a time.—S. ARNOTT.

Begonia Gloire de Lorraine.—The compact bushes of this beautiful plant that were so much admired at the Drill Hall last week showed the value of this for winter flowering. The pots, too, in which the plants were growing were only 5 inches in diameter, the plants themselves slightly balloon-shaped, being 15 inches to 18 inches high, and at the most globular part of the plant nearly a foot through. What struck one most of all was the perfect manner in which the

plants had been turned out, a remarkable instance of high-class culture in a plant that shows the least bruising or crushing.

Notes from Hopton Hall.—I send you a picture of one division of the orchard here. The whole is laid out in large square plots with wide grass walks. Strawberries are planted among the Apple trees. The north is protected with a high rough stone wall rapidly being covered with Roses. The whole length of the border is a mass of gorgeous colour produced by *Crocus* planted last autumn. The other picture is part of the other division of the orchard, showing *Britomas* with, on the wall, Roses, as *Rève d'Or*, *Bouquet d'Or*, *Gustave Regis*, now a mass of colour, and *Gloire de Dijon*.—G. BOLAS.

Aster cordifolius Diana.—While large-flowered Asters are very desirable, those with small flowers produced in great numbers must not be neglected. Some of these have a most elegant habit, and there is much beauty in the sprays of tiny flowers so many of them give us. No collection of Michaelmas Daisies can be said to be complete which does not contain some of these small-flowered varieties. *A. cordifolius Diana* is not so new as some, but is likely to remain long in favour. In my light soil it grows about 3½ feet high, and has erect stems with sprays of beautiful little lavender flowers.—S. ARNOTT.

Saxifraga peltata.—I enclose you a photo of *Saxifraga peltata* growing by the side of my lake, where the damp soil suits it splendidly. The leaves are very large, each quite 18 inches across. It is a handsome plant and looks well wherever you see it from. It loves a damp, sheltered spot, its natural habitat being in California, growing by the side of water. The flowers are produced in the spring before the leaves appear, and are on stalks from 1 foot to 2 feet high. In front, inside a wire guard, I grow in the water the Japanese *Iris* (*Iris Kämpferi*), the *Saxifrage* forming a good background to this beautiful *Iris* when in flower.—G. DIXON.

Aster grandiflorus.—In spite of the great heat of the past summer, this handsome species of Starwort does not appear a success in the open garden. This is due in all probability to the intense heat of midsummer, coupled with the absence of moisture, which together checked the growth of many plants. Indeed, quite ordinary subjects were at a standstill for some time, as may be gathered more clearly now that their season of flowering is here. The same thing occurring to this Starwort would account for the lateness of the plants to show flower. It is unfortunate so beautiful a plant is so late blooming, as this renders it all but useless in the open garden.

Calceolaria Burbidgei.—In the large conservatory late in summer and through the early autumn months this species is very effective. In smaller buildings the height to which the plants attain would preclude its use, as not infrequently does it reach to 8 feet and even more. At Kew at the present time there are plants fully the height stated in flower in the greenhouse, and the large blossoms, which are of a rich and decided yellow, render it a striking plant when amid suitable environment. This fine hybrid is the result of crossing *C. Pavoni* and *C. fuchsifolia*, the plant having originated with Mr. F. W. Burbidge at the College Gardens, Dublin.

Sternbergia lutea in Scotland.—So unsatisfactory are the various *Sternbergias* in the south-west of Scotland, that I am pleased to learn in a letter from Mr. Robinson-Douglas, of Orchardton, that *S. lutea* has flowered with him this year. This, Mr. Robinson-Douglas remarks, has not flowered with him for some years. I can only regret that I have not been so fortunate this season, as my bulbs have not given me a bloom. This is the invariable experience here since the first season after planting when *S. lutea* flowered. When Mr. Whittall sent bulbs of *S. macrantha*, which flowered the first season, I was in hopes that it might prove

more suitable to our climate than *S. lutea*. Unfortunately, this is not the case, and I have to regret that these fine autumn bulbs will not bloom here with ordinary treatment.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Carnation Nox.—In the interesting notes on Carnations lately in THE GARDEN, "H. S." refers to this new dark self as a "first-rate gain." But is not this endeavour, which aims at making step by step these beautiful garden flowers so dark that we shall soon see them of a sooty black hue, a rather doubtful gain? I think Nox can only be a gain in that it is the darkest kind that has yet appeared among Carnation seedlings, for it is much too dark for effective gardening. In the open, beds of it would carry but little weight, while as a button-hole flower it would be quite out of place, unless a special white background be made for the occasion. Regarded as a border flower, which is the true place for the variety named, Nox would be dull and dark, while Mephisto, a shade or two lighter, would produce a far better effect.

Flowers in October.—Autumn, and yet summer still in garden colouring. A magnificent mass of *Begonias*, white, red, pink, and yellow, as large in flower and full of colour as on an August day, is growing beside a bed of *Heliotrope*, still full of bloom. Under the wall immense plants of *Fuchsia* are rich with a wealth of blossom. Pale lemon *Calceolarias*, beside tall bushes of elegant *Pentstemons* in white, pink, and deep maroon; enormous bushes of bright blue *Hydrangeas*; *Chrysanthemums* making masses of white and yellow; *Starworts* of many kinds, mixing with *Evening Primrose*, *Hollyhocks*, *Tobacco flowers*, *Marguerite Daisies*, scented *Verbena*, and Japanese *Anemones*, make a profusion of blossom. Seldom have *Dahlias* lasted so long into the autumn. Still from tall poles *Ivy-leaved Geraniums* fling great trusses of deep-coloured flowers, and the *Clematis*, untouched by frost, weighs down the arches over the kitchen garden walk. In the Rose bed, great bouquets for the drawing-room may yet be cut from *Mme. Nabonnand* (perhaps the most useful of all the late-blooming Roses), *Pernet-Ducher*, *Princess de Sagan*, *Anna Ollivier*, *l'Idéal*, *W. Allen Richardson*, and *Papa Gentier*. Sheltered in a corner near the house an immense cluster of beautiful *Belladonna Lilies* is in fullest bloom, while the large masses of *Marguerite Carnations* furnish an invaluable supply of cut bloom.—D., *October 17.*

Stokesia cyanea.—The flowering of this plant in the open border is by no means a common occurrence. It is very distinct not only in the branching character of the plant, but also in the colour of the flowers and the construction of the root-stock. It is this latter character that renders propagation by division a most uncertain method, as frequently there is a one-legged stem for an inch or more under ground, which is scarcely suggested by the tufted crown of leaves that cluster thereon. Uncertain, therefore, by division, too late in flowering also for any hope of securing seeds, would appear to almost preclude the idea of increasing the plant at all. It is, however, one of the most easily raised of all composites by means of root cuttings. The roots produced are long and fleshy, and when cut into lengths and put into greenhouse warmth are not long in showing signs of life at the apex of the cutting, which is always best just exposed. So reliable is the plant in this respect that it is rarely a root perishes—at least such as may be counted of sufficient size. Even where not needed for the border, the habit of the plant is so good and its flowering so profuse as to render it quite worthy of being grown in pots for greenhouse decoration. At the last meeting of the Royal Horticultural Society the plant was noticed in flower in at least two collections. By inserting root cuttings early in January and growing in pots till the end of May there is hope—in the southern counties at least—of securing many flowers in a favourable and mild autumn.

TREES AND SHRUBS.

RAPID GROWTH IN A YEW TREE.

ONE of the most remarkable Yew Trees in England is growing at Shugborough, near Staf-

eighty or more years ago. The gravel is apparently derived from the old red sandstone, and there is no sign of chalk, which has been supposed to be essential to the healthy growth of Yew trees, in the vicinity. The age of this tree is, I take it, almost precisely that of the

now at Kew on the wall of the herbaceous ground a large specimen a dozen feet high or so and about the same in width is flowering with remarkable freedom, and is in this stage decidedly ornamental. This *Vitex* is in a warm, light soil rather a free-growing shrub clothed with compound leaves, the leaflets of which are of a lightish green and hoary beneath, thus imparting to the entire plant quite a greyish appearance. The flowers, which are borne in terminal branching panicles, are arranged in whorls, and though individually by no means attractive, they form collectively a decidedly ornamental feature, and at this season of the year, too, with very few shrubs in bloom, they are additionally welcome. This *Vitex*, known also as the Chaste Tree, occurs in a wild state along the shores of the Mediterranean both in Europe and Africa. It has been long known in this country, having been introduced in 1870, but at the same time it is very rarely seen.—T.

Yew tree at Shugborough, near Stafford. From a photograph by Mr. F. Bonney, Colton House, Rugeley.

ford, the seat of the Earl of Lichfield. It is noteworthy, not only for its form and for the extraordinary spread of its branches, but for the manner in which they have taken root and for the rapid growth of the young shoots after rooting. In some instances these have made from 12 inches to 15 inches in the present year (September 26). The main stem girths 10 feet 2 inches at 3 feet, and 12 feet 6 inches at the ground, and consists of three separate trunks, welded together up to 4 feet 9 inches. Its height is 42 feet. All the lower branches touch the ground, rooting all round, leaving one entrance. The longest radius is 43 feet 6 inches, and the diameter 87 feet, circumference 261 feet. One of the rooting branches measures 7 inches in girth at 8 feet 6 inches from the trunk. At 8 feet from this point it had a girth of 27 inches. Another measures 10 inches at 6 feet 6 inches from the trunk, and the upright stem, 23 feet from this point, girthed 24 inches. In several instances the branches rooted a second time. This peculiarity of the branches taking root is, so far as I know, unique. Even the Clontarf tree, which greatly resembles it in size and appearance, having a very similar mode of growth with a diameter of 76 feet, has none of its branches rooted. The tree at Crom Castle, Fermanagh, would have had much the same habit had not its branches been raised from the ground on props and the trunk mutilated at an early period.

The Shugborough tree owes its vigour, apparently, to its growing in gravelly soil, about 7 feet above the river Sow, a tributary of the Trent, and to the free supply of water from this source and from a pool of water near to it on the other side, which existed there

Clontarf tree, between 250 and 300 years, but from the combined character of the trunk the former number is probably the more approximate age. The Crom Castle tree, which has a similar girth, has a record which makes it appear as 159 years old, but its girth is no doubt increased from its having been lopped and trimmed at an early period.

JOHN LOWE.

Pernettyas.—A group of these forming a compact mass of foliage and covered with berries reminds one that sunshine and heat must shortly give place to the leaden skies and murky atmosphere that too frequently characterise our English winters. Neat of habit with glossy evergreen foliage and laden with berries of varying colours, these *Pernettyas* are of immense value for the winter embellishment of the outdoor garden. I was told that at Oakwood the birds do not take the berries very early, so that these fruit-laden little shrubs give us the full measure of their beauty at a time when something bright cheerful is most needed. I noticed more particularly a clump of these *Pernettyas* forming a mass of foliage and smothered with many-hued berries, every berry being fully exposed to the eye. This, I believe, is due to the fact that annual pruning is practised at Oakwood. I saw other groups with long upright growths, and which were not nearly so attractive. Anything more pleasing than a group in fruit it would be difficult to find at this season.—J. C. B.

Vitex Agnus-castus.—At no time can this be regarded as a showy shrub, while it is also too tender for many districts of England. Even in the neighbourhood of London it thrives better as a wall plant than in the open ground, and just

NOTES ON HARDY SHRUBS.

CLEMATIS ORIENTALIS.—This is not one of the most showy species of *Clematis*, but the late season at which it flowers and the unusual colour of its blossoms make it well worth a place in the garden. It is a climber of vigorous growth, reaching a height of 12 feet to 15 feet. Commencing to flower in August, it continues through September and, if the weather be not too wet and cold, into October. The blooms are very freely borne, and each one measures upwards of 2 inches across, the colour being a tawny yellow—one of the rarest shades to be seen in *Clematis* flowers. They are, like most of these late-flowering species, fragrant, but not so strongly as is *C. flammula* or *C. paniculata*. The foliage is thin and of a pale, slightly glaucous green. The species is a variable one, owing no doubt to the extensive area over which it spreads in a wild state. It reaches from Persia and the Himalaya to Manchuria. It is sometimes grown under the name of *flava*, although a still better-known synonym is *graveolens*.

KOELREUTERIA PANICULATA.—This is a tree of medium size—that is, between 20 feet and

Base of Yew tree at Shugborough, near Stafford. From a photograph by Mr. F. Bonney, Colton House, Rugeley.

30 feet high—which grows wild and in great abundance on the hills near Peking, also in other parts of China, but it does not appear to be, as has sometimes been stated, a native of Japan.

It is deciduous, and chiefly noteworthy for its very distinct and handsome foliage. The leaves, each about 1 foot long with the leaflets deeply lobed and toothed, are of a rich dark green in summer, turning a deep yellow before they fall. The tree produces its flowers towards the end of the summer in light branching panicles; they are small, of a dull yellow, and without perfume. The four oblong petals are all on the upper side of the flower. It only produces fruit in exceptionally favourable years, such as the present. The species was introduced by Lord Coventry about the year 1763, and flowered and fruited at Kew so long ago as 1787, yet specimens of full size are very rare, possibly owing to the tree being naturally short-lived. Recently a new species has been obtained from China. This is *K. bipinnata*, distinguished by its doubly pinnate leaves. It has not yet flowered here, but there is a fine batch of young plants at Kew raised from seed sent by Dr. A. Henry from China. Koelreuter, after whom the genus was named, was a German botanist and cultivator, still remembered by the number of experiments he made in the artificial fertilisation of plants.

CALYOPTERIS MASTACANTHUS.—However much the heat and the long drought of the summer and autumn may have adversely affected many shrubs and plants, they have evidently suited this, which I have never before seen so strong or so finely in flower. The mildness of the two preceding winters has doubtless been in its favour, for it is a plant that suffers during our hardest winters if left without some kind of protection, and although not often killed outright, it is liable to start weak and late, and even by the end of the growing season is no larger than it was at the same period of the previous year. It has now, however, had three seasons of unchecked growth in which to acquire its natural vigour and beauty, and is now a compact, rounded bush 5 feet through and 3 feet high. It is of semi-woody growth and belongs to the *Verbena* family, producing its flowers in short, semi-globular cymes, one of which occurs in each of the axils of the leaves. The blossoms are closely packed in each cluster, which are of a bright and pretty blue, the lower lip of the corolla being fringed. The leaves are each 3 inches to 4 inches long, woolly, and coarsely toothed. It was first introduced from China by Fortune, but afterwards was lost to cultivation, and was not seen in English gardens till Mariès re-introduced it from Japan when collecting there for Messrs. Veitch. It is best, perhaps, grown near the base of a wall; in the open it ought to have a winter covering of dry leaves and branches. It thrives with little or no protection in places on the Continent, where they experience considerably harder frosts than we do here, but that is the case with many shrubs, and is simply due to the greater amount of sun-heat they get in summer, which ripens up and hardens the growth, and makes it much better able to withstand cold than our comparatively soft and sappy wood.

HYPERICUM HOOKERIANUM.—Considering the comparative scarcity of autumn-flowering shrubs, it is certain that the *Hypericums* might be advantageously used to a greater extent than they are at present, more especially in country gardens (of which there are many) where there is a special desire that the gardens should be as bright as possible from the middle of August onwards. Of the taller-growing *Hypericums* the species under notice is the best and handsomest, occupying in that group much the same position as regards merit that *H. Moserianum* does among the dwarf species. Hooker's *Hypericum* is, however, the hardier. It is a

native of the Sikkim Himalaya at an elevation of from 8000 feet to 12,000 feet, and is found also in Assam. In some of its native haunts it grows as much as 8 feet in height, but here it appears to be about half as high. It has reddish bark and fine foliage, the oblong leaves being nearly or quite sessile and 1 inch to 3 inches long. It commences to flower in August and keeps on through that and the following month. This year it is quite gay now—at the beginning of October. The flowers, of a rich golden yellow, about 2 inches across and slightly cup-shaped, the petals full and broad and of good substance, are produced at the top of the plant in corymbose clusters. Lobb was the first to send this *Hypericum* home, having found it on the hills about Mullong, in Assam. There is a variety of it in cultivation called *Leschenaultii*, but it is of little value as an outdoor shrub, coming from lower elevations, and consequently more tender than the type.

THE CROSS-LEAVED HEATH (*Erica tetralix*).—This is the commonest of the true *Ericas* in Britain, and although it does not cover our moors, heaths and mountains to the same extent that the common Ling or Heather (*Calluna vulgaris*) does, it is widely distributed in the three kingdoms, and covers large tracts in some districts. It is now past its best, but is still in flower. The blooms are produced in an umbel at the top of the stem, from five to about a dozen on each. The corolla is rose-coloured (the upper side being of much the darker shade), contracted towards the mouth and swollen towards the base. The leaves are arranged in fours crosswise at each joint; their margins are rolled back under so as to make them appear narrower than they really are. From the nearly allied *Erica Mackayi* this is distinguished by the pubescent calyx and seed-vessels. The plant is deep green and healthy in appearance. There is a variety with white flowers, and another found by Mr. Borrer in Cornwall which is remarkable for the curled woolly hairs with which it is covered. The cross-leaved Heath is a useful autumn plant in positions where dwarf subjects only are wanted; it grows from 9 inches to 18 inches high.

HYDRANGEA HORTENSIA.—At this season of the year there is nothing perhaps among flowering shrubs that strikes the northern gardener so forcibly on entering the favoured gardens of the extreme south and south-west of England for the first time as this old and popular plant. To him it has hitherto been a greenhouse plant solely, but in the Devonshire and Cornwall gardens he sees it a vigorous, hardy shrub, crowded with its huge trusses and making a gayer display than anything else just now. In Mr. Rashleigh's garden at Menabilly it lines the carriage road much as the Laurel or Rhododendron does further north. Although near London it never produces so fine a show, it may occasionally be seen nicely in flower. This autumn, for instance, it has produced a goodly number of trusses, this being due to the absence of severe frost for nearly three years, which has enabled its shoots to survive the winters and the plants to gain annually in strength. Severe frosts, even of short duration, cut it back to the ground, and although it springs up freely enough afterwards, it is very rarely that these one-year-old shoots flower. It is not a plant that likes fierce sunlight. I notice this year in full exposure its leaves have turned quite yellow. It is better planted with other shrubs that can afford it both shade and shelter. No plant name is more persistently mis-spelt than this. It is generally written *H. hortensis*; properly it is, as given above, "*H. Hortensia*," the specific name being really adapted from an

old generic name for this *Hydrangea* and its varieties. Even when the name is spelt correctly, its derivation is nearly always erroneously given. I must confess to having sinned in this matter myself. For the sake of correctness, the following extract may be quoted from a French book called "*Inventaire des Cultures de Trianon*," written by Le Comte Jaubert, and published in Paris in 1876. The work is interesting to tree lovers because the gardens at Trianon were the favourite ones of the French royal family previous to the Revolution, and many of the first American and Oriental trees introduced to France by Michaux and others were planted here. With regard to the specific name of this *Hydrangea*, Count Jaubert says:—

It is generally believed that the *Hortensia* bears the name of Queen Hortense, daughter of the Empress Josephine, and for this reason it was used sometimes, under the Second Empire, as a political emblem. This is a grave error. The plant was dedicated by Commerson to Mme. Hortense Lepaute, wife of a celebrated clock-maker of Paris, whose friend the botanist was (p. 29).
W. J. B.

NOTES & QUESTIONS.—TREES & SHRUBS.

Hardy Fuchsias.—The note by "E. M." on the splendid examples of hardy Fuchsias growing in gardens around Cromer reminds me of the fine bushes of *Riccartoni* which used to grow in the pleasure grounds at Blickling. They were planted along the centre of a wide grass verge on each side of a long pleasure ground walk and looked charming. *Fuchsia Riccartoni* is a capital variety for planting in round beds on well-kept grass, the long weeping shoots laden with small brilliant flowers having a particularly graceful effect in autumn.—C.

The Tulip Tree.—Few trees enrich the landscape in late autumn better than a good variety of the Tulip Tree. Even in early summer its glossy foliage and quaint blossoms are very interesting, but it is when the foliage has taken on a beautiful golden hue and is viewed from a distance on a sunny, breezy, autumnal day that its real value for park adornment is seen. The wonder is that the Tulip Tree is not more often planted. The finest specimens I have seen are in Thorndon Park, Brentwood. There is also a fine specimen in Langley Park, Norwich.—C.

Planting the Spanish Chestnut.—It seems this does not receive the attention in this country it merits. Apart from its commercial value, the tree is very ornamental, especially when grown as an isolated specimen with plenty of room. Frequently it is seen huddled up amongst other trees in plantations, where it gets no chance of development. There is a vast difference in the fruit produced by different trees, some being small and almost worthless for eating. In sandy soils in East Anglia the Spanish Chestnut thrives well. A row of trees I know in a sunny position close to a wide stream of water yields good crops of nuts, which for size and quality quite equal those sent from abroad.—J. C.

DESTROYERS.

Wasps.—In his note on wasps (p. 261) Mr. Burrell inquires if I had noted whether these were altogether responsible for the damage done to Pears, or if they follow in the wake of tits. With me the sampling of the fruits by tits is invariably followed by the attacks of wasps and bluebottle flies. I notice that they do not always wait for the small probe of the tit if the latter has its attention directed to some other source—Sunflowers, for instance. Most of my Pears are grown on large bush trees, and while the tits find abundant food from these the wall Pears do not suffer serious molestation; indeed, it is only in exceptional cases that damage is done to Pears on the walls; nor do the tits seem to take the trouble to go beyond the bush trees in order to carry on their mischief. It is surprising the extent of damage a few birds will do. In the spring, or rather the early summer, I made a determined effort to decrease their numbers by

destroying every nest containing eggs, but although not nearly so numerous as in other years, they are, nevertheless, too abundant now. Sunflowers seem to have an even greater attraction for the tit than fruit when the seeds are ripening.—W. S.

Birds versus insects.—I know of but one bird that befriends the gardener in taking caterpillars as food, and that is the cuckoo. Gooseberry trees are safe so long as this bird can be induced to visit the garden and is not molested in any way. Doubtless even the cuckoo would be surfeited in dealing with the myriads of caterpillars there are in evidence just now everywhere. I can never remember a time when garden vegetables of the Brassica tribe were so completely defoliated as now. The black fly which infests Peaches, Plums, and Cherries in the summer, so far as concerns birds, remains undisturbed; so must the Celery fly, Turnip flea, and an aphid now appearing in strong force among new Cabbage plantations. The harm done by birds every year throughout the fruit season is too well known, and I have yet to learn in what direction to look for compensation for the havoc so wantonly committed. The thrush I always favour because of its fondness for the house-snail and white slugs. Seed-eating birds, such as the linnets and finches of different kinds, are of no value in destroying insects. There are some smaller birds that do good in this direction no doubt, but they seem not to be in attendance when most needed. I cannot, therefore, agree with "J. G." that we are suffering from a depopulation of the feathered tribe as affecting the good they do in destroying insect enemies of the garden. Here there is abundance of birds, migratory and native, and unfortunately, too, there is a greater number of insects, winged and otherwise. The protracted drought does undoubtedly explain away much of the trouble.—W. S., *Rood Ashton*.

NOTES ON PEAS.

We have to thank our numerous correspondents throughout the country for the interesting replies to the following queries regarding Peas:—

- (1) Which do you consider the best Peas—new or old—taking into account cropping and good flavour?
- (2) Which do you consider the best early, the best midseason, and the best kinds to yield a supply into the late autumn?
- (3) What is the best time to sow Peas for an autumn supply?

—The drought has told heavily upon the crops of Peas this year, especially the later varieties. The tropical heat and consequent extreme aridity of the atmosphere caused the flowers to curl up instead of set properly, followed by attacks of mildew, and although the late rows of Peas were grown in trenches and heavily mulched and watered, the crop was somewhat unsatisfactory. Early and midseason varieties gave good results. I rely upon three early varieties, viz., Veitch's Selected Early, Early Giant Marrow, and Gradus, with a few rows of William the First and a breadth of Chelsea Gem, followed by Main-crop, Master-piece, Autocrat, and Veitch's Perfection. My sheet-anchor late Pea is that good old variety British Queen, always reliable and a far better successional cropper than any other kind known to me. Its only drawback is the very tall sticks required, but the fact of being able to gather Peas in so long a succession from the same rows is no small advantage and well worth the extra height of stakes. This kind has a strong, robust constitution, and I have sometimes used 6 feet wire netting, 4 inch mesh, fixed to stout stakes when ordinary sticks were scarce, a roll of netting on either side of row and sloping outwards, with excellent results. My latest sowings have turned out best, when sown from June 1 to middle of same month, but the seed must be sown very

thinly. Such rows give high quality Peas into October, according to weather.—W. CRAWF, *Madsfield Court, Great Malvern*.

—Peas this year have been very good. I sowed the following sorts on the same day:—Selected Lightning, Early Morn, Daisy, Early Giant, Excelsior, Seedling Marrowfat, William Hurst, English Wonder, and Chelsea Gem. Of these I consider Early Giant the best early sort. It is of true Marrowfat flavour, a good cropper, and grows about 4 feet high. If a second sort is wanted, Excelsior might be given that place. Early Morn I do not consider of true Marrowfat flavour, but it is a fine cropper, the Peas being of a pale green colour. Daisy is a fine Pea in all respects, but not early enough for a first early. For midseason varieties I consider Prizetaker, Autocrat, and Alderman the best. Eureka is the heaviest cropper I know, but the pods do not carry that nice dark bloom seen on Prizetaker and Autocrat. For yielding a late supply I give the first place to Autocrat and Alderman. The best time to sow for late use is, I find, from the 5th to the 10th of June.—JAMES DYMOCK, *Stoke Bruerne Park, Tamworth*.

—I grow William the First and William Hurst for early use, and they give every satisfaction. For midseason Peas nothing beats Duke of Albany and Telegraph. I always put in a sowing of Walker's Perpetual Bearer in March, and it comes in very useful and is a splendid-flavoured Pea. It is no good sowing later than the second week in June. As a rule I put in my first Peas on the 1st of February, and then once a fortnight until June.—THOMAS SIMPSON, *Stourton Court, Stourbridge*.

—Within recent years many sterling varieties of Peas, which are undoubtedly decided improvements on the majority of the older sorts both as regards cropping, flavour, length of pod and size of Peas, have been introduced. A few of the older sorts I still adhere to for sowing early in the season on account of their being hardy, but even these will have to give way to the newer earliest Marrow Peas should the latter continue to give satisfaction. For second early, main crop and late supplies I have discarded the majority of the older kinds, with one exception, and that is Veitch's Perfection. This sort is subject to mildew in some places. Here it is all one can desire. I consider the newer introductions as grown here to be superior to the older sorts, with the exception of the reservation mentioned above. I have hitherto found Veitch's Selected Early and Dickson's First and Best to be the two best early Peas, but this opinion has been modified in favour of Veitch's Earliest Marrow. The last-named sort is quite as early as the sorts first quoted and infinitely superior to them in every way, both as regards cropping and quality. Harbinger, another fine early Marrow, is but a few days later, and is a first-rate Pea of most excellent quality. The best midseason Pea here this season, taking everything into consideration, is Veitch's Main-crop. This is a splendid sort, an enormous cropper, and the quality is first-rate in every particular. For yielding a supply into late autumn I find nothing to equal Autocrat and Sturdy. The best time for sowing here for autumn supply is from the beginning until the end of June. By sowing the two sorts just named in their order at intervals through the month I seldom experience any difficulty in having Peas late in the autumn or until the plants are cut down by frost.—A. WARD, *Stoke Edith Gardens*.

—The first crops of Peas are sown in the open ground, the dwarf ones on a border, towards the end of February or early in March, according to the season and the state of the soil. The varieties chiefly depended upon are Chelsea Gem and Wm. Hurst for dwarfs, the former being considered the better of the two, May Queen, Veitch's Selected Extra Early, and William the First. All of these produce excellent crops and of good quality. The next sowing includes Gladiator, which is considered one of the very best, and Dr. Maclean also invariably does well as a succession. Later on Autocrat, one of the

most reliable, Criterion and Ne Plus Ultra, the last still one of the best flavoured, are sown. I make the latest sowing early in June, but sometimes get only a very poor supply in autumn, as they are attacked most years with pests of various kinds, which prevent anything more than a moderate return. The two first sowings generally do better than later ones, and this season is no exception. Several other varieties have been grown, but those named have been the best both as regards cropping and flavour. When mildew or thrips do not spoil the crop I have to net as a protection against hawfinches and tomits, which eat the young Peas soon after they are formed. Netting, however, is after all only a partial remedy.—J. GARRETT, *Batsford Park, Morilton-in-Marsh*.

—Varieties of Peas are so numerous, or sent out under so many different names, that a selection of the best is a difficult matter. Quite recently I noted that a grower for private use was recommending over a score of varieties; but, fortunately, there is no need to grow so many, less than a dozen sufficing for all needs and being far more satisfactory to the cook. For the first crop, those who prefer a green Pea will find nothing better than Springtide, a fine cropper, very full-podded and handsome, the flavour being equal to that of any other of the very early Peas, and the plant hardy. Chelsea Gem is also a splendid early Pea, and I have for many years made this my standard early variety, and to succeed it I depend on an old favourite, Dr. Maclean. Gradus, too, is a grand second early, and now that it is again possible to obtain it true, it will take some beating. Thomas Laxton, of which I grew a few this year for trial, is a magnificent variety as far as can be judged, the pods large, the Peas green, very sweet, and closely packed in the pods. It came in within a week of the first earlies, and I feel sure that it will prove a valuable addition. Criterion is the first of the main-crop Peas, and its splendid qualities are too well known to need any further remarks. As I do not care for any of the very large-podded Peas, of which I may take Duke of Albany as an example, I follow Criterion with another old variety, Champion of England, which is a fine cropper and well flavoured. Sharpe's Queen is a fine main-crop Pea and suitable for those who have a difficulty in getting tall sticks. From the first week in August I depend on successional rows of Ne Plus Ultra to provide the supply until Autocrat comes in to finish the season. Ne Plus Ultra can hardly be beaten for quality and hardness, its only fault being that it runs to a great height, but it bears prodigiously. Of Autocrat I make two or three sowings from the middle of May to the first week in June, and the last sowing provides a supply up to the time when frost puts an end to the crop. Autocrat and Carter's Michaelmas are the two best late Peas I have grown, and the quality of both is splendid; they resist mildew well, and I have never seen either in an unhealthy state. I grow a few rows of Springtide and Chelsea Gem in addition to the above for late work, but do not find that they are so generally useful as the late varieties proper. I find it useless to sow even these early varieties later than the last week in June here, as early frosts are prevalent. The varieties mentioned in the above note are those on which I am depending this year. Others of equal merit might possibly have been included, but these are sufficient for the requirements.—J. C. TALLACK, *Livermore Park Gardens, Suffolk*.

—Early kinds grown are Chelsea Gem and Veitch's Selected Extra Early: both sorts bore excellent crops. The Selected Early came in a week earlier than Chelsea Gem, followed by Exonian. Main-crop was the next to come into use, and I think this Pea bore as good a crop as anything I ever saw, and the quality A1: it grew over 1 feet 6 inches this year. I have grown it several seasons and it is one of the best for mid-season. Veitch's Perfection is a favourite with me, but will not compare with Main-crop as a garden Pea except in quality. The next is Duke

of Albany, a good cropper and of good quality, about 5 feet 6 inches this year in height. Closely following this comes the grand old Pea Ne Plus Ultra, which requires plenty of room. This year it was about 6 feet 6 inches to 7 feet in height, and the crop is splendid in every way. I have tried a Pea this year for the first time called Exhibition Marrow. It seems to be well worth growing, having large pods and large Peas of good quality, and is quite 4 feet high this year; I shall try this variety again. The next in rotation is Veitch's Autocrat. I grow Dwarf Mammoth for later use, and I generally make a sowing about the third week in July of Omega or some other good dwarf Pea for a chance late crop, and sometimes I get a fair lot of Peas from a sowing made about that time, but it all depends on the weather.—J. HOLLINWORTH, *Maryon Park Gardens, Taubach, S. Wales.*

The early sorts I sow are Veitch's Exonian and Selected Early; second crop, Criterion; third, Criterion and Duchess of Edinburgh; next Veitch's Autocrat, and last crop Ne Plus Ultra. All the above I find in good seasons keep up the supply from about the second week in May up till September. I find the end of June a good time for sowing the last crop of Veitch's Autocrat and Ne Plus Ultra, both of which I consider excellent late Peas.—JAMES COOMES, *Englefield, Reading.*

Gradus I consider the best early Pea. It is quite as early as American Wonder or William Hurst. The best midseason one is Duke of Albany, a splendid Pea, a good bearer, and very sweet. The best time I find to sow for late use is the middle of June; those sown about the 1st of July are only able to get the pods formed when the frosty nights set in, so that they never fill.—ROBT. MCKENNA, *Charleville Forest, Tullamore.*

After three years' trial, I consider Sutton's Perfection the best main-crop Pea, the Peas being large, pods well filled, and flavour excellent. It is an enormous cropper and lasts good longer than any other sort I have grown. Were I restricted to one Pea for main crop, this would be the one I should select. Ringleader I grow for first crop. Sown in the open border in February, it comes into use in the beginning of June. I have almost abandoned the practice of sowing Peas under glass and planting out, as it entails a lot of labour with small returns. By making a sowing in a warm border in the first week of November, I gather nearly (if not quite) as early as from those sown under glass and planted out, with double the crop. No crop pays better for liberal treatment than Peas, deep trenching and heavy manuring on light soils being, in my opinion, the surest way to obtain abundance of good Peas. I generally select for the main crop ground that has been cleared of Strawberries the previous autumn, trench it 2½ feet deep, and throw it up into ridges during the winter. Late autumn Peas have not been a success the last two dry seasons. Having tried several of the newer sorts so highly recommended for autumn supply, I find that Telephone and Telegraph have been the most useful, bearing splendid crops and lasting until the middle of September. After that date I do not count upon a regular supply of Peas for various reasons. Years ago when in Roxburghshire I used to have Veitch's Perfection Pea in grand condition in the beginning of October. Here I have tried it several times without success.—DAVID KEMP, *Stoke Park Gardens, Slough.*

For the past few years I have tried numerous varieties of Peas, both early, midseason and late. I find William I. suit this climate best as an early Pea. Gradus is a capital Pea, but with me it is ten days later than William I. Boston Unrivalled, though classed as midseason, turns in here quite as soon as Gradus, sown on the same date. It is a strong grower, a heavy cropper, and when cooked of fine flavour. I look upon it as one of the best new Peas. For a mid-season supply I find The Duchess, Duke of Albany, Alderman, Barnet Hero and Dr. McLean to be the best. Alderman is a splendid Pea, an enormous cropper, producing its pods in pairs

and of the finest flavour. Barnet Hero is a dwarf-growing variety, the average height being 3½ feet, the haulm covered with deep green pods, carrying from seven to nine peas of first-rate flavour. For autumn supply I sow William I. on June 15 and Boston Unrivalled on the 20th. I get far better returns by sowing early sorts on the above dates than sowing later ones two or three weeks earlier.—R. J. SULLINGTON, *Valleyfield House, Penicuik, Midlothian.*

STOVE AND GREENHOUSE.

DAFFODILS IN POTS.

It is not generally known what very beautiful subjects Narcissi are for greenhouse and conservatory decoration in early spring. The soil for potting should be good turfy loam rather strong than otherwise, with a dash of sand and a little good leaf-mould to keep it open. The bulbs should be potted in October for flowering about March; earlier if the flowers are wanted

Narcissus Empress. From a photograph sent by Messrs. Pearson and Sons, Chilwell, Notts.

sooner. The later-blooming plants will always be the finer; very early flowers will be at the expense of size and substance. Make the soil firm, but not hard. When the potting is finished, the necks of the bulbs should be level with the surface of the soil. Five bulbs per pot is a good number. Emperor and some of the largest bulbs will require an 8-inch pot, while for the smaller kinds a 6-inch will be large enough. It is better to err on the side of having too many to the pot than too few; two or three bulbs in a pot produce no effect.

Having potted the bulbs, place the pots out of doors on a bed of ashes or something that will exclude worms, and cover them with some 6 inches of cocoa-nut fibre, old tan, or similar light material. Avoid coal ashes, and leave untouched until the time comes for bringing into the greenhouse. This will vary according to the time the blooms are required, but if early flowers are wanted, early preparation must be made by early potting; it is useless to

attempt to force the bloom unless the roots have had full time to develop. When properly covered, as advised above, no amount of frost will harm the plants. In 1894-95 some were frozen up under fibre until well into March; the leaves had grown through the fibre, and nothing could be moved until a decided thaw set them at liberty. These plants produced most beautiful blooms, though of course rather late.

When removed to the frame or greenhouse where they are to flower, Daffodils should be placed near the glass to prevent drawing, and should have all the air that can be given with safety. No water need be given while in outside quarters, and not much will be required until growth is pretty well advanced. When the buds are showing well liberal supplies may be given, especially to the stronger-growing kinds, but avoid a sodden condition of soil.

When out of bloom the bulbs may be turned out without disturbance, only removing the drainage. The clump may be planted in the open ground, where the bulbs will gradually ripen off without further attention, and be useful for planting out the following autumn, but must not be relied upon for pot work. Emperor, Empress, Maximus, Telamonius plenus, Obvallaris, Sir Watkin, Parri conspicuus, Minnie Hume, Leeds amabilis, and Cynosure are some of the best varieties for pot culture. Some are not so showy as others, but all are beautiful in their way, and the blooms being kept free from dust and smuts are particularly fresh and dainty looking.

PEARSON AND SONS,

Chilwell, Notts.

Forcing Lachenalias.—Undoubtedly the finest and brightest spikes of these beautiful spring-flowering plants are obtained in a cool greenhouse temperature; still they will submit to a gentle forcing, and were so treated in several gardens in Norfolk last spring, good spikes of bloom being forthcoming at the beginning of February. From one place bunches of Lachenalia Nelsoni were sent to London for sale and realised a good price, purchasers finding them last a long time in water.

If fresh water is given and a portion of the base of the stem cut off they will remain in good condition for a fortnight if not confined to too hot a room. The bulbs should not be forced two years in succession.—C.

Begonia Gloire de Lorraine.—This beautiful winter-flowering variety is now too well known to need any description, but a word or two as to what it will do throughout the winter may be of interest. It was generally supposed that it would not make a plant large enough for anything beyond a 5-inch pot, yet if the early flowers are taken off and the plants potted or into 6 inch or even 8-inch pots, they will make fine specimens and continue to bloom even longer than those in smaller pots. By giving a little liquid manure frequently and keeping the plants well exposed to the light, they will continue to bear a mass of bright pink bloom well into April. Some varieties, especially hybrids, seem to deteriorate, but this is an exception, at least so far as my experience goes, for this season it has made more vigorous growth and finer plants than I have ever seen before. The great secret of success with this Begonia is to get good healthy plants to start

with. Those propagated from flowering shoots never branch out and make well-furnished plants. —A.

LAPAGERIAS IN POTS.

THERE is a common belief that Lapagerias, except in a few isolated cases, do not succeed satisfactorily under pot culture. That perfect success,

Narcissus Santa Maria. From a photograph sent by Messrs. Pearson and Sons.

however, can be secured under pot treatment is fully proved by the splendid specimens sometimes exhibited at the various exhibitions. At Shrewsbury, grand, healthy plants are annually shown, the white one in particular being very telling. Some years ago a fine plant was on view in the Victoria Nurseries, Holloway, bearing no less than 400 blooms. I confess I did not succeed thoroughly with it in pots so long as I gave it a perfectly cool temperature all the year round, but found no difficulty at all after giving it an intermediate heat during the growing season. My greatest success was with a plant grown in an early lean-to Peach house, the pot being stood on a thick plank resting on the hot-water pipes close to the front lights, the roots being thus under the influence of a gentle bottom-heat. After repotting in November in a compost of fibrous yellow loam and peat in equal parts, to which were added liberally small lumps of sandstone and a sprinkling of charcoal, the plant was introduced into warmth towards the end of the month, the temperature being gradually raised from 45° in November till it reached 65° in March and April. The slight bottom-heat soon induced, besides ordinary growths which started from the previous year's wood, strong succulent shoots to push up through the soil. These as well as the smaller growths were tied to strings fixed some 18 inches below the roof glass, up which they rapidly climbed, until in some instances they reached a length of 12 feet, the leaves on the stronger growths being nearly as large as a man's hand and dark and leathery. A slight roof shading was given for a few hours only in the hottest part of the day, and the foliage freely syringed morning and afternoon, the roots being assisted frequently with diluted liquid manure. Growth usually ceased in May, and there were quickly formed from the base of almost every leaf dense clusters of bloom, as many as eight blooms in each, these being when fully developed extra large and of good colour. In June the growths were taken down and carefully distributed over a balloon trellis, the plant, after being subjected to cool airy house temperature for a time, being stood in the front hall of the mansion, where it was much admired. I have seen the white and red varieties planted out

and the growths trained together over a corridor, the mixed colours having a very elegant appearance. I would advise those who may have failed with the Lapageria in pots to give it the treatment above described. NORWICH.

Thunbergia grandiflora. The remarks of "H. P." (page 277) on this not-often met-with stove climber should induce those who have plenty of heat and space at command to give it a trial. Its delicate blooms when produced in quantity have a very striking appearance. The first plant of this Thunbergia I saw was at Hutton Hall, Yorkshire, a good many years ago, and I then thought what a fine subject it would make for exhibition. As "H. P." observes, it needs plenty of heat room, also a well-drained rooting medium, this to consist of equal parts rough peat and loam, with a free addition of sandstone in pieces the size of walnuts, charcoal and silver sand, as the plant when in a vigorous state needs a good amount of root moisture. When pot-bound and restricted to roof space, the foliage soon loses its colour and is very liable to become infested with insects. —NORWICH.

GREENHOUSE HEATHS.

KINDLY give me the fullest instructions as to the right treatment of greenhouse Heaths.—M. ARDEN, *Fulbrook, Barton-under-Needwood.*

** In order to attain the best possible success in the culture of greenhouse Heaths, the following points need to be noted, viz., houses suitable for their culture, soil in which to pot them, and the potting and watering of them in a careful manner at all times.

HOUSES, &c.—These should, if possible, be span-roofed, not too lofty, but well ventilated. The old-fashioned houses, now fast becoming extinct, used to suit Heaths well, but there is no reason why the lighter and better ventilated ones now built should not suit them much better. What is now needed is a light shading when in flower, the arrangement for which should not be a difficult matter, No. 3 netting being ample for the purpose. Span-roofed houses are preferable, for the simple reason that the plants can be kept all round alike, whilst damp, always an enemy to these Heaths during the winter, can be dispersed much more readily. The plants should be so arranged as to nearly touch the glass, for the nearer they are so placed the more sturdy will be the growth—a most essential point in their cultivation. Sufficient heating power should be provided to keep out frost at all times, but without having to resort to excessive fire-heat, which, on the other hand, will exhaust the atmospheric moisture too much, making it harsh and dry. During frosty weather never aim at keeping Heaths at all warm, for so long as the temperature is maintained just a degree or two above freezing point no harm will come to the plants. This, of course, is the night or minimum standard, whilst 40° may be taken as that for the daytime. At other times when there is no frost do not employ any fire-heat at night, but a little during the day when damp and dull will be beneficial, causing greater buoyancy in the atmosphere. At other seasons ventilate freely both by night and by day. Let the ventilation be done in a rational manner during a period of easterly winds. Damp down the floors and between the plants after a warm, sunny, or otherwise parching day, but not

during damp or dull weather. Mildew is the one enemy of Heaths more likely to do harm; let it therefore be looked after very closely. Plants of dense growth, such, for instance, as the *ventricosa* and *vestita* sections, and *Cavendishi* and *hyemalis*, are most disposed to foster it. Sulphur is the best remedy, applied by means of a sulphur puff, or by a syringe if the plant be large and very dense.

SOIL AND POTTING.—The soil for Heaths is peat and sand only when the former is of the suitable kind. The peat best adapted to Heaths is that which is when handled of a harsh, hard character, having in it traces of the roots of hardy Heaths. This peat can scarcely ever be had very thick, not half the thickness of that used for Ferns and Orchids. It is often cut (and supplied, too) in too thick turves, hence frequently there is waste as far as the Heaths are concerned; the lower or under part is often void of fibre, therefore not fit for the purpose at all. In colour the best Heath peat is quite dark. Should the peat be lighter in character, with the possibility of becoming sour sooner, it is better to add the faintest possible dash of fibrous sandy loam with a small amount of nutty charcoal or finely-broken corks. Do not break the soil up too finely, but rather keep it coarse, for so long as it can be worked down properly around the ball it is quite fine enough. Pot thoroughly well and quite firmly. Take pains in respect to this, and a deal will be gained by it afterwards. Use sand rather more freely than with most plants, bearing in mind that the potting is permanent. Only give what is termed "one shift," which will allow of nearly 1 inch all around the ball. Keep the crown of the plant slightly elevated rather than otherwise, finishing off the surface quite firmly. The better time to repot Heaths is after flowering, this allowing in most cases a sufficient time for the plants to become partially re-established before winter sets in. Late summer kinds may, on the other hand, be left until the following spring before being repotted. See that the condition of the soil and

Narcissus Mrs. Thompson. From a photograph sent by Messrs. Pearson and Sons.

that of the ball of the plant nearly correspond as regards moisture.

WATERING, &c.—Give a thorough watering a day or so after repotting, and afterwards watch the condition of the plants for a time quite closely. As a rule it may be accepted that

Heaths are more frequently ruined by drought at the roots than by excess of water. It must not be inferred from this that a Heath is an aquatic; far from it; but if the fine hair-like roots become parched it frequently means their death. Sounding the pots with the knuckles is the best test as regards watering. When once a grower has mastered the art of watering Heaths, he has accomplished the most difficult part of their culture. Give sufficient water to penetrate the ball, watching the condition of the plants as the inspection and watering are being done. Rain water is much the best, and it will pay to store this for Heaths. Special care is needed in treating Heaths in small pots, such, for instance, as those which are sold at this season of the year by thousands. These are more often than not quite root-bound, and are in consequence very liable to suffer from drought. The following kinds are cases in point, being what may be termed gross feeders, viz.: Cavendishi, hyemalis, and Wilmoreana, as well as the ventricosa section. On the other hand, the hard-wooded kinds (all Heaths are termed hard-wooded, but some possess a slower growth, which in its turn is more woody and hard) do not absorb so much water. These latter are the more difficult to grow, such, for instance, as the tricolor section, Massoni major, Paxtoni, McNabiana, retorta major, aristata major, &c., which are amongst the finest of all greenhouse plants that can possibly be selected.

In commencing the culture of greenhouse Heaths, the advice of an old grower is to begin with the softer-wooded kinds, as hyemalis, gracilis, Cavendishi, Wilmoreana, Spenceriana, mammosa, and cerinthoides. Then afterwards start upon the harder-wooded varieties when confidence and experience have been gained. It should be stated that Heaths may be stood out of doors during the summer with advantage in all but the most exposed situations.—PLANTSMAN.

TREE CARNATIONS.

My experience is that in dry seasons Tree Carnations do not make the progress they do when favoured with an average rainfall. In very wet summers if great care is not exercised with the watering-pot and the plants at times even laid on their side, the foliage, owing to continued root-saturation, is sure to become a prey to the yellows, and many collapses have to be recorded. On the other hand, when the atmosphere is parched for weeks together, some varieties, Miss Joliffe in particular, are liable to take on a sickly bluish hue, and these, if even they survive till housing time arrives, are almost sure to go off during the winter. In trying seasons the syringe ought to be freely plied amongst the plants, and the bed of ashes on which they stand frequently well moistened at eventide. This treatment should be continued throughout the autumn, unless night dews are frequent. These are a great help to Tree Carnations, and often assist the plants to grow out of any weakness or temporary check they may have sustained from attacks of aphid. In hot, dry summers aphid is usually more troublesome, and if this pest is not speedily eradicated, growth will soon practically come to a standstill; and if once the leading growths assume that yellowish cast which Carnation growers so much dislike, the earliest blooms will either be deformed or poor in quality. Some growers are apt to be in too great a hurry in moving the plants into their winter quarters, especially should a few frosts occur, but if these are not more than a few degrees and the roots are not in a softened condition from heavy rains, they will be all the better in the open till, say, the middle of October. The nearer the plants are placed to the roof glass the better, and it is very important that they should have a syringing morning and evening, sprinkling the floor and stage as

well, in order that no check may be given from a sudden change of quarters. The house should be mildly fumigated two evenings in succession directly housing is completed, after which all air possible should be admitted night and day till frost arrives, no fire-heat being used unless the night temperature is likely to fall below 40°. Coddling is ruinous. C.

SALVIA SPLENDENS GRANDIFLORA.

THIS is one of the most showy flowering plants we have at this season of the year. Unfortunately, the flowers drop when subject to a change of temperature, but in the conservatory the same plants keep up a bright display for a considerable time, and quite large specimens may be grown from cuttings struck in April. Where smaller plants are desired, the cuttings may be put in at any time up to the end of June. It may be grown in any ordinary soil and gives little trouble either in propagating or growing on. The greatest difficulty lies in keeping some healthy stock through the winter. If only a few plants are kept and properly cared for, better results will be obtained than keeping a large number and putting them in an unsuitable position. After cutting the flower-stems off, the plants should be placed in a light open position in an intermediate house, taking care that they are kept free from red spider and other insects. Some cuttings may be put in early in the year, and if potted on as soon as ready they will soon give healthy cuttings and the old stock can be discarded. During the summer the plants will do well out of doors or in a cold frame. If plenty of room is given, no stopping will be necessary, as the plants will branch out naturally. Being subject to the attacks of red spider, the syringe must be used freely. One great advantage in propagating from healthy young shoots late in the season is that they are not so liable to get overrun with insects. Although this *Salvia* will do well out of doors during hot weather, it will show the effects of the first cold nights, and should therefore be housed not later than the end of August. As soon as flowering commences, liquid or artificial manure may be used freely. *Salvia* Bethellii and *S. Hoveyi* are good companions to the above, and deserve more attention than they often get. The bright blue *S. Butcheri* is also a very useful plant. F. H.

USEFUL WINTER PLANTS.

THE work of potting up and housing the various subjects useful for winter work, as *Salvias*, *Eupatoriums*, *Bouvardias* and *Solanums*, is now completed, and they all promise a capital display. I have planted all these out during the summer months for several years, and although the result, perhaps, is no better than that obtained from pot culture throughout, the plants always do remarkably well, and a considerable saving is effected in the way of labour in watering, especially if the summer prove hot and dry. They are planted in shallow trenches, allowing sufficient room to develop into nice bushy stuff, and, beyond one good soaking and a mulch, get no other attention until the time comes to cut round them preparatory to lifting. One or two of the scarlet *Salvias*, of which more plants were put out than are required for potting, remain in the trenches, and having escaped the frost are flowering finely. They are grand autumn flowers, and very effective for occasional dinner-table work. I remember a row some years ago backing up some finely-flowered plants of *Bouvardia Humboldti eorymbiflora*, and the effect was very fine. With me this *Bouvardia* is very uncertain, sometimes developing into fine bushes and flowering freely. In other seasons the growth is ragged and irregular and the heads of flower few and far between. Whilst on the subject of failures I may note that another grand winter-flowering plant, *Lasiandra macrantha*, is not a success with me if planted out. I have seen this system advocated, and have tried a small batch

on more than one occasion with other things, but they never did well. Two or three varieties of late *Chrysanthemums* are always included in the list of planted-out stuff. They make nice bushes and furnish a lot of cut bloom. There are doubtless many varieties suitable for the purpose. I rely chiefly on *L. Canning* and *Golden Dart*. Pots of sufficient size not being to hand, I have this season placed this batch of *Chrysanthemums* along the back wall of the Peach house. A 9-inch board on edge was run along parallel with the wall and about 12 inches away, with just a few stakes on the outer side to keep it up. The *Chrysanthemums* were then placed inside the board and soil packed tightly about them. Such a batch of *Chrysanthemums* will be found very useful towards the end of the year, especially in those places where there is little opportunity of producing a quantity of forced flowers. The weather experienced through the summer and early autumn was very favourable to a firm, short-jointed growth on winter-flowering *Pelargoniums*, and they are now showing a grand lot of bloom. If material for cutting as well as a display is required, the doubles are much the more serviceable. E. BURRELL.

Clarcmont.

NOTES AND QUESTIONS.—STOVE.

Pelargonium Souvenir de Prince Albert.—On page 277 mention is made of an Ivy-leaved *Pelargonium* under the above name, which, I think, must be intended for *Souvenir de Charles Turner*, as the other is quite unknown to me, and I fail to find it in any list or catalogue available. If *Souvenir de Charles Turner* is the variety intended, I can fully confirm the favourable opinions expressed by "H. R."—H. P.

Swainsonia galegifolia alba.—Like "E. M." (p. 258), I can strongly recommend planting this out in summer. I recently saw fine plants in this condition at Streatham Hall, Exeter. Mr. Franklin told me this was his usual custom. As the days got cold these were potted up and removed into a cold house, where they continued to bloom a long time. This method differs from that adopted at Dillington Hall, in Norfolk, where the plants are cut back in spring, shaken out, and potted when starting into growth. About June these are placed in the open. I have seen plants fall of bloom in December at this place.—DORSET.

SEPTEMBER IN SOUTH DEVON.

DURING the past month rain to the amount of 0.80 of an inch has fallen on 6 days against 3.09 inches on 15 days during the corresponding month of 1897, the average for September being 2.42 inches. In the past nine months of the present year 13.96 inches of rain have fallen on 96 days, against 26.93 inches on 132 days during the similar period in 1897, the average for the nine months being 22.83 inches. We are thus at the present time 8.87 inches below our average rainfall for the year, with only three months left to make up the remaining 20 odd inches between the 13.96 inches already fallen and the yearly average. The month has been a remarkably bright one, 213 hours 25 minutes of sunshine having been registered, or 55 hours 40 minutes in excess of the month's average of 157 hours 45 minutes, while the amount recorded for September, 1897, was 156 hours 35 minutes. The large amount of sunshine in the past month has raised the record for the first nine months of the year considerably above the average, which is 1479 hours 30 minutes, the present year's sunshine aggregating 213 hours 25 minutes, while that for the corresponding period of 1897 amounted to 1495 hours 35 minutes. During the past September there was not a single sunless day. The mean temperature of 61.8° is high for the month, the average being 57.9°, and the record for September, 1897, 56.1°. The highest sun temperature of the month was 119.8° on the 15th, and the highest screen reading 76.3° on the 8th. The lowest screen temperature was 46.2° on the 29th, and the lowest grass reading 41.3° on the same date. The month has been very windless, almost

as much so as the record month of five years, September, 1895, when only 3175 miles of horizontal movement was recorded. The total movement of the wind has been 3827 miles, against 6291 miles in the corresponding month of last year. The highest daily run was 332 miles on the 30th, and the greatest hourly velocity of 25 miles was attained between the hours of 6 and 7 a.m. on the same date. The wind was south to west on eighteen days and north to east on the remaining twelve, though on some days there was so little wind movement that it was practically immeasurable. The average amount of ozone in the air during the month has been 51 per cent. of the possible, running from 80 per cent. on three days during south-westerly winds down to zero on days with an east wind. Notwithstanding the extreme dryness of the month, there is as yet but little sign of autumn in the foliage of the trees. The Chestnut that in 1897 was showing traces of crimson and gold before August had departed in this year of a uniform green tint on the last day of September. The swallows and martins are still numerous, the latter on still afternoons soaring at such an altitude, that those unacquainted with their diverse modes of flight might easily mistake them for the swifts, which have long since deserted our shores.

In the garden, *Achillea ptarmica* fl. pl. The Pearl has continued to blossom, and the light blue of *Agathæa celestis* has been conspicuous in the border, while, until the closing week of the month, the white Japanese *Anemone Honorine Jobert*, in many situations over 5 feet in height, has been flowering profusely, and in the wild garden the *Aeanthus* still rears its tall bloom-rods. The Starworts have been particularly effective during the past month, since no rough winds have arisen to mar the tall, graceful flower-sprays, although the dry weather has, perhaps, curtailed the beauty of the individual blossoms. *Aster Amellus bessarabicus*, which is one of the most lasting of the Starworts, often being in bloom for close upon three months, has been very attractive; indeed, this, the earliest, and *A. grandiflorus*, the latest of the Michaelmas Daisies, exceed in size of flower all other varieties. Three white varieties have bloomed in quick succession, *A. Novi-Belgii* Harpur-Crewe leading the way, followed by *A. N.-B. niveus*, and a few days later by *A. polyphyllus*. *A. puniceus pulcherrimus*, lavender-white, has had its tall sprays thickly studded with flowers—so thickly, indeed, as in some cases to impart a slightly heavy appearance to the flowering shoots. *A. N.-B. Robert Parker* holds the palm as the most elegant in growth of all the larger flowered Asters, the blossoms, too, with their pale mauve tint, being large and shapely and not too thickly set upon the graceful sprays. Long flower-stems of this *Aster*, loosely arranged, form an exquisite indoor decoration. *A. N.-B. Pluto* is a good dark-flowered variety, the blossoms being of a purple-blue. Of the smaller flowered kinds, *A. cordifolius* and *A. cordifolius elegans*, the former white and the latter pale lilac, both became very ornamental by the close of the month, when *A. erieoides*, with its numberless minute Daisy-like blooms, commenced to approach perfection. The red *A. Nova-Anglie ruber* and the purple *A. N.-A. Melpomene* have also been blossoming, but Starworts of this section do not possess the decorative qualities, either for garden work or as cut flowers, that the *Novi-Belgii* section exhibits. The dwarf *A. dumosus* has been a clump of bloom only from 6 inches to 9 inches high, and the old cottage favourite, *A. diffusus horizontalis*, has produced its countless small maroon and white flowers. Neither of the two last-named varieties are worthy of culture except in collections or for the sake of associations, their places being easily filled with worthier and showier subjects. *Aster* (*Chrysocoma*) *Linosyris* has produced its bright yellow inflorescence and amply justified its English name of Goldilocks. The tuberous *Begonias*, unmindful of the drought, have formed a glorious sheet of vivid colour, edged with a

salmon-pink hanging fringe of Ivy-leaved *Pelargonium* *Mme. Crousse*, and backed, towards the conclusion of the month, by a deep row of pale pink *Belladonna* Lilies. Varieties of *Campanula carpatica* have been in good bloom in many gardens, and the large-flowered *Cannas* are still bright, while *C. Ehmanni iridiflora* is producing spike after spike of drooping rose-pink blossoms. The *Marguerite Carnations* are largely used in gardens now, and pretty pictures they make when grown in masses, the dense blue-grey foliage forming a base of soft colouring, to which the many-tinted blossoms act as accessories without disturbing the broad colour-effect of the setting. The *Valerian* (*Centranthus ruber*), in its three colours, pink, red, and white, is to be seen blossoming on the railway embankments and on cliff ledges. The early-flowering *Chrysanthemums* are in bloom, and the Autumn *Crocus* (*Colchicum autumnale*) has produced its pale purple chalcices. Autumn-sown plants of *Cosmos bipinnatus* have been in bloom since the end of the summer, and those sown and brought on under glass have also been flowering for some time, but those sown in the open have not as yet expanded a blossom. *Crimum* *capense* has been blooming well, several large-flowered umbels being in perfection at the same time on a bed in the vicinity. *Cactus Dahlias* have been exceedingly decorative throughout the month, some especially telling flowers being *Arachne*, cream, shaded red; *Charles Woodbridge*, bright crimson; *Daffodil*, pale yellow, very good; *Esmeralda*, orange-scarlet; *Harmony*, apricot; *Island Queen*, lilac; *Lucerne*, orange-red and yellow; *Magnificent*, fawn; and *Mary Service*, salmon. Here and there a blue flower-spike of *Delphinium* shows, and a few large golden stars expand week by week on clumps of *Doronicum plantagineum excelsum* Harpur-Crewe, while *Dianthus Napoleon III.* was still flowering brightly at the commencement of the month. *Erigeron speciosus*, after a prolonged season of bloom, has produced September blossoms, and the little Mexican Daisy (*E. mucronatus*) is, if anything, a still more persistent bloomer, having flowered steadily on from the early spring. The Coral Tree (*Erythrina crista-galli*) was a fine sight early in the month, with its long spikes of crimson blossoms, two or three of which were still bright at the commencement of October. *Fuchsia Riccartoni* is to be met with in huge bushes, crimson with bloom, in many a cottage garden, fine specimens being especially common at the mouth of the river Dart. *Gaillardias* are still bearing their blossoms of crimson and gold, and *Gazania* are not yet flowerless, while the Cape *Hyacinth* (*Galtonia candicans*) has borne many a late spike of ivory bells, and the double scarlet *Geum* makes at intervals a bright spot in the border. Yellow is a prevailing tint in the autumn garden, the Golden Rod (*Solidago ambigua*) holding its own and flowering profusely in out-of-the-way corners of the wild garden, while the perennial Sunflowers throw a yellow glow over the borders. *Helianthus rigidus* Miss Mellish and *H. latiflorus* have both been very decorative with their bright golden blossoms, and a long group of *H. giganteus*, whose tall heads are fringed with a galaxy of pale stars, stands out well against the green background of the distant Elms. Many of the annual Sunflowers are still beautiful in September, though the earliest brown discs are already rayless, and where they are allowed to remain on the plants droop lower and lower beneath the increasing weight of the seeds. In warm corners *Hedychium Gardnerianum* has perfected its lemon-tinted spikes of fragrant blossoms, and in some gardens the Everlasting Flowers (*Helichrysum*) with their bright artificiality are blooming freely. In the favoured climate of South Devon the *Hydrangeas* assume gigantic proportions, and may be seen in all colours from bright pink to Forget-me-not blue, edging shrubberies, growing by the great boles of Elms and other deciduous trees by winding drives, or spreading billows of massive blooms beneath the latticed cottage windows. *Hypericum Moserianum* has also been in flower, and the scarlet heads of the *Kniphofias*

have associated well with the gold of the Sunflowers. For brilliancy, however, there is nothing to compare with the vivid colouring of *Lobelia fulgens*, whose flower-spikes last in beauty for many weeks, and will still be bright when October has well-nigh waned. The deep pink blossoms of *L. rosea* are also pleasing in colour, but are killed by the glowing hue of the last-mentioned variety if the two chance to be growing in proximity to one another. Marigolds are here and there still in bloom, and the double variety of *Matricaria inodora*, with its Fennel-like foliage, is white with blossom, while early in the month the orange-red flower-scapes of the *Montbretias* were in evidence. The sweet-scented Tobacco plant (*Nicotiana glauca*) has flowered with undiminished beauty and fragrance, and the pale yellow blossoms of the giant Evening Primrose (*Oenothera Lamarckiana*) have expanded their frail petals in the background of borders and in the wild garden.

The Tufted Pansies have continued blossoming in some situations, but the dry weather has in many cases rendered them flowerless. Paris Daisies, where the old flowers have been removed, are now in bloom, and the Ivy-leaved *Pelargoniums* *Mme. Crousse* and *Souvenir de Charles Turner* have been objects of beauty throughout the entire month, while the *Pentstemons* have been blossoming freely. *Phygelius capensis* has been a striking plant with its branching racemes of scarlet blossoms, and the Winter Cherries (*Physalis Alkekengi* and *P. Franchetti*) became conspicuous towards the end of the month as the calyces assumed their bright orange-red hue. Some of those borne by *P. Franchetti* are particularly large, one that I measured the other day being 9 inches in circumference; in spite of this, however, it is doubtful if the older variety is not to be preferred for indoor decoration. In the early part of September the herbaceous *Phloxes* were bright in gardens not too dried up, while occasional blooms were produced by members of the Poppy family. *Plumbago* *Larpetense* flowered profusely, covering rockery and border with the soft blue of its blossoms. *Polygonum capitatum* has also been in bloom, and *Pyretbrum uliginosum* has produced on its tall stems a host of narrow-rayed, white star flowers, much in request for floral arrangements in tall vases. The Tea Roses have been blooming uninterruptedly throughout the month, and have yielded many a bowlful of fragrant suavely-coloured blossoms. The white *Macartney* Rose has also flowered abundantly, daily expanding fresh blooms charming in the simplicity of their single petals and golden-stamened centre, while their faint perfume, resembling that of a ripe Pear, is very pleasing. *Rudbeckia Newmanii* has been and still is a handsome sight, a 3-foot wide clump being literally covered with black-centred, orange stars. The lasting qualities of these blossoms are remarkable, the petals being of such consistency that they withstand even heavy rains without injury. *R. purpurea* was in flower during the earlier part of the month, but does not approach *R. Newmanii* in the abundance of flowers produced. The deep Gentian-blue of *Salvia patens* has been conspicuous in the border, and is extremely effective in conjunction with the bright vermilion of *Lobelia fulgens*. Other *Salvias* in bloom are *S. coccinea* and *S. fulgens*, both of the latter often living through the winter in South Devon. Spring-sown plants of *Scabiosa caucasica* have borne their lovely pale blue blossoms, and both *Sedum Sieboldii* and *Stokesia cyanea* commenced to bloom in mid-September, while the Sweet Peas, where they have not been allowed to seed, are still bearing their softly coloured blossoms. *Tradescantia virginica* has exhibited the deep purple of its blossoms in the border, and towards the end of the month I saw at Kingswear, growing in a garden overlooking the entrance to the river Dart, *Tuberoses* in flower that were the produce of bulbs planted in the open border in the late spring, and which had had no protection from

the time of their planting. As a rule, Tuberoses that are flowered in the open border are started comparatively early under glass and planted out when tolerable-sized plants in the early summer. *Zauschneria californica*, which grows like a weed in most South Devon gardens, is again bright with its vivid scarlet flowers. Many annuals still brighten the garden with their varied hues, the scarlet *Zinnias* being most effective when massed in considerable quantities, while the yellow and white of Sweet Sultans, the blue of Cornflowers, the orange and gold of *Eschscholtzias*, and the shot-silk lustre of the velvet-petalled *Salpiglossis* have combined to enhance September's floral attractions. Of

SHRUBS,

Abutilon vexillarium has kept up a succession of crimson and yellow blossoms on its slender arching shoots, and *Aralia spinosa* has produced its ivory-white inflorescence. In cases where this *Aralia* is grown as a standard, with a straight stem some 10 feet or 15 feet in height before it is allowed to branch, its effect, with the large spreading leaves, is quite Palm-like, its appearance being especially attractive when the foliage is crowned with the long flower-clusters, which from a little distance have almost the appearance of parchment-coloured ostrich plumes. *Caryopteris mastacanthus*, generally treated as a greenhouse shrub, is now in flower, the colour of its blossoms being much similar to that of the blooms of *Agathaea euclestis*. It has now lived out for two winters, but would doubtless be killed in a severe winter if not given protection. *Ceanothus Gloire de Versailles* is a delightful sight when large bushes are seen laden with their light blue flower-panicles, as they have been during the past September. Another attractive shrub that blossoms at much the same period is *Escallonia montevidensis*, whose white flower clusters have a wonderful fascination for the butterflies, which resort in numbers to quite small specimens. Late in the month I witnessed a pretty sight, fourteen red admirals having settled on the flowers of one bush, the velvety black and bright scarlet of the butterflies' wings contrasting delightfully with the *Escallonia's* white blossoms. Early in the month the pure white Rose of Sharon (*Hibiscus syriacus totus albus*) was in blossom, and the Venetian Sumach (*Rhus Cotinus*), with its iridescent clusters of purple-red inflorescence, was a picture of surprising beauty. This Sumach is not nearly so well known as it should be, its autumnal effect being unique and striking in the extreme. The Sea Buckthorn (*Hippophae rhamnoides*) towards the conclusion of September was responsible for a charming colour effect, the orange berries contrasting pleasingly with the grey-green of the foliage, while *Yuccas* of several varieties threw up great spires of bloom, *Y. gloriosa* in particular perfecting flower-spikes 4 feet and more in length. The great standard *Magnolia* continued to produce its fragrant white chalcids with undiminished prodigality, and during the past six years has never flowered so profusely as it has this season, many of the sprays being terminated with two instead of one bloom-bud and scarcely a single spray over the whole tree being flowerless. The month closed with scarce a sign of autumn in the colouring of the Virginian Creeper (*Ampelopsis hederacea*) or its clinging variety, *A. Veitchi*, but the seed vessels of *Clematis Vitalba* are already growing grey on tree and hedgerow. *Clematis graveolens* has been in bloom, as has *C. songarica*, which possesses flowers smaller than the former variety and of a rather paler shade of yellow. The seed vessels of *C. graveolens* have a pretty effect when seen against a dark background, and the plant is a rapid grower, soon covering a large space of wall. The Virgin's Bower (*C. flammula*) has produced its odorous flower-wreaths in profusion, and the purple of *C. Jackmani* is still apparent in places. *Convolvulus mauritanicus* has been blossoming, and the Passion Flower is displaying both flower and fruit simultaneously. The oval orange seed-pods hang amid the pile star flowers, while both are backed by the dark green of the leaves. A fine plant of *Plumbago capensis* which

has lived unharmed through two winters, planted against the face of a cliff in a sheltered position, is covered with blue flower-clusters through its 10 feet or so of height and breadth. This plant is in rude health and is growing in an exceptionally vigorous manner, its shoots being very different in appearance from the spindly growth generally made by these plants when given a position in the open in specially favoured localities.

The Flame Nasturtium (*Tropaeolum speciosum*) bore its brilliant scarlet flowers during the early portion of the month, its purple seed-berries being now beautiful. *T. tuberosum* has commenced to show its blooms of bright orange and red, and the Canary Creeper (*T. canariense*) has spread bright trails of gold over rock wall and trellis, while a variety of the scarlet *T. Lobbianum*, that passed through the winter uninjured, has covered the side of a small house with a sheet of glorious colour. *Solanum jasminoides* becomes more beautiful with each succeeding month. It is now, perhaps, at its best, and has been in bloom since April, and will to all appearance flower profusely throughout the whole of October. Undoubtedly this *Solanum* is the flowering creeper *par excellence* for the south-west of England.

There has been a moderate crop of Apples, but many varieties have borne unusually large fruit, bush trees of Bramley's Seedling, Peasgood's Nonsuch, Lord Derby, Bismarck, and Warner's King bearing a quantity of fruits each between 1 lb. and 1½ lbs. in weight. Cox's Pomona has produced very large and highly-coloured fruit, and Cox's Orange Pippin a fair crop, but mostly small-sized. Apples on the Paradise stock do not succeed well on this soil and make scarcely any growth, while those on the Crab have done excellently and have made fine growth, besides bearing well.

S. W. F.

KITCHEN GARDEN.

DWARF BEANS IN PITS IN AUTUMN.

I HAVE so far never been able to grow a profitable crop of Beans in what may be termed the mid-winter months, and provided a good plant is secured and flowers set, one may get a fair crop by sowing in September or the first week in October and growing on quickly. Few vegetables bear more quickly, and with good weather the plants set their crop before the dark days of December. Even in frames or pits one does not get full crops like those in the open, but Beans at the season named are valued in the kitchen. I fear we shall not have very much choice as regards the early winter vegetables, as, owing to the heat and drought, Cauliflowers and early Broccoli do not look at all promising, and there has been a great difficulty, delay also, in getting the winter vegetables planted, so that a supply of Beans will be valuable at the period named. No time must be lost in getting the plants up, and for this purpose I always use new seed. The seed is sown in 4½-inch pots filled with rich soil, as root-action must be rapid. Five to eight seeds are sown in each pot, these when up being thinned as may be found necessary. The pots are placed in Cucumber houses over hot-water pipes to assist rapid germination, and in a few days are ready to move into another place. Of course a heated pit is necessary at this time of year, and if there is heat under the bed so much the better. Much is not required, but a little warmth helps to set and swell the pods. A great depth of soil is not required, 6 inches to 9 inches being ample, but this should be good. I use bonemeal with spent Mushroom soil if the loam is at all poor with a liberal addition of wood ashes or old mortar rubble. In heated pits or frames the growth is rapid, and when a fair set has been secured there is no trouble in getting the pods to swell, as food may be given freely in the shape of liquid manure or a quick-acting fertiliser. A liberal temperature with ample supplies of atmospheric moisture is needed from the start. The

pipes, however, should not be overheated, as if this is the case red spider will be troublesome. An early variety should be sown. Early Favourite, Syon House, and Sutton's Forcing I have found very good. G. WYTHES.

Imported Onions.—I have lately been surprised at the large quantities of Onions of the Giant Rocca type that have been hawked through the city of Norwich. The vendors are Frenchmen, and one of them stated that a shipload of Onions was brought to Yarmouth from France and then disposed of in the nearest East Anglian towns. The bulbs are by no means large, but splendidly ripened, and being strung on cord are shown off to advantage. They are offered at a cheap rate, and it is to me a wonder, after the cost of growing, shipping and vending has been defrayed, that it pays.—N.

Winter Kales.—I would advise those who have a large demand for spring vegetables to pay a little extra attention to the late-planted breadths, as these will give a supply at a time green vegetables are none too plentiful. In many gardens water is difficult to get, and the late plants that followed summer crops are feeling the effects of drought badly. I have placed litter over the roots to conserve the moisture given. Fortunately, I have been able to give an occasional supply of liquid manure, and the plants, though not at all gross, are of a good colour and repay for the extra attention given. I fear the early Cabbages will be none too good if the drought continues, so many plants going blind.—S. M.

Rosette Coleworts.—Acres of these are grown by market growers in the neighbourhood of London, but around most other large towns they do not seem to be much grown. Market growers would, however, find them answer well during the winter months, as they are most delicious after a few frosts. One sometimes sees them in private gardens in use in autumn when there is plenty of Cabbages, Marrows, and Beans still to be had, consequently they are of little value. This is due to sowing the seed at the wrong date. About the second week in July is a good time for sowing for the production of nice-hearted Coleworts during November and December, a second sowing being made for a batch for January cutting. I always plant a lot on plots from which two-year-old Strawberry plants have been cleared off. No digging is required, merely putting the plants in with a trowel.—J. C.

GARDEN FLORA.

PLATE 1193.

THE ALPINE STARWORTS.

(WITH A COLOURED PLATE OF *ASTER ALPINUS* AND VARS.*)

ASTER ALPINUS and the several varieties thereof are undoubtedly among the most valuable things in or near the rock garden. The value of any such plant, regarded of course from the point of view of effect, can have nothing whatever to do with its rarity or costliness. Rather should it be considered from the standpoint of easy culture. The alpine Starworts, all beautiful dwarf free-flowering subjects, require perhaps the least care of any plant in the open rock garden. It is here, indeed, that we note the value as well as the beauty of these plants, the varieties of which need no elaborate description whereby they may be recognised. In this respect the coloured plate in the present issue is so faithfully representative that detailed description is superfluous. Even were it otherwise, the plants generally are so well known that few who have a hardy plant garden will be

* Drawn for THE GARDEN by H. G. Moon in the Royal Gardens, Kew. Lithographed and printed by J. L. Goffart.

found without them. It so happens, however, that at times ease of culture acts to the disadvantage of the subject, and this is not altogether untrue in the present instance. Plants that are proverbially difficult to manage, be their value great or small, frequently receive every attention, while those that are hardy and enduring are allowed to take their chance.

It is so with the alpine Asters figured to-day, for while among the most beautiful of early summer alpine, it is only rarely that we find them in the best condition. Despite the fact that these plants are recommended for the "rock garden or border," most of them are best suited in the former, provided they are well planted in good soil. Of some of them it is quite easy to form a patch 3 feet across in a season or two, yet for some reason or other these alpine Starworts are usually planted in single clumps. Nothing could possibly have a better effect early in the summer than broad masses of these showy subjects in good positions in the rock garden. Why they should not be so grown it is not easy to say, seeing the rich and varied display the large flower-heads give. One of the chief drawbacks, if not, indeed, the only one, is the fondness of slugs for certain varieties and in certain seasons and localities. In the rock garden, however, the plants are usually more free of this pest, and luckily so, as once slugs take to a clump they are so secure from observation as to be able to pursue their work of destruction undisturbed. The plants thrive best in good rich sandy loam about 15 inches deep and made quite firm. In light sandy soils that are usually dressed heavily with manure each year I have planted some hundreds of seedlings, that have made splendid tufts 6 inches to 8 inches across in a year, putting forth a display of blossoms quite surprising for the age of the plant. To some extent, of course, this freedom would be due to their being seedlings, though to some extent also to the rich, deeply-worked soil. Where large borders exist it is a good plan to raise seedlings freely and form edgings of them, at flowering time selecting a few of the best and most striking shades. In this way a strain of some excellence may soon be secured, though as a rule the proportion of poor weedy forms is very considerable.

The accompanying plate gives three of the most distinct of the cultivated forms, all of which are worth growing freely.

ASTER ALPINUS, which has been known nearly 250 years, is worth growing as an early spring bedding plant, flowering in May. Thus employed a very pretty effect may be secured from the numerous flower-heads and the varying tints of lilac and blue-purple seen in the ray florets. It is about 6 inches high. The white variety, growing about 6 inches high, is a pretty and useful kind, but open to considerable improvement, both in form and size. The pink variety is perhaps the most charming of all, the warm rosy pink hue being very pleasing. Indeed, in the rock garden at any season this shade would be welcome among the dwarf plants, and every attempt should be made to secure a good stock of this kind. The plant usually flowers in May and is known as *A. a. ruber* and *A. a. roseus*.

A. a. SUPERBUS is a large and showy kind and an improvement on the original: it is also generally bolder and stronger in growth. The most vigorous member of the group, however, is

A. a. SPECIOSUS, which will in good soil attain from 9 inches to 15 inches in height. In any position, however, its superiority may at once be seen, more particularly in the large and richly-coloured flower-heads, the latter of a clear violet-blue shade and nearly 4 inches across. This is a fine addition to this section and shows the value of raising seedlings of such things.

In their distinctive colours these plants can

only be reliably increased by division of the roots in the early spring. E. J.

THE WEEK'S WORK.

FRUIT HOUSES.

POT VINES.—Where pot Vines are depended upon for first early forcing no time should now be lost in doing what little pruning is required, such as cutting away any lateral growths or foreshortening the rods if too long, or if not quite ripened to the apex. After this work is done, dress all the wounds with styptic if at hand, or with painter's knotting, which is equally as effectual. Do not allow the Vines to become absolutely dry at the roots, nor, on the other hand, give them too much water. If it be doubted as to the canes being properly ripened, let the Vines be kept in a well-ventilated house where a little warmth in the pipes is available. This, however, should not be the case after the weather of the past four or five months. Do not think for one moment about re-potting these Vines now; it will only end in failure in nearly every case if it be done. A selection of those most fit should be available for starting by the beginning of November. My own practice has been to start them steadily about November 9. Previous to starting the canes let them be dressed with an insecticide, not too strong, as a safeguard against such insect pests as red spider and thrips. It is to be hoped nothing worse in this way is in evidence. Mildew needs to be looked after also very closely. Young Vines raised this year from eyes may now be put away for the winter in a fairly sheltered spot, where the pots can be plunged in litter of some kind to protect the roots from frost. A semi-pruning can also be given them at the same time. It should be noted that no Vines in pots ought ever to be exposed to frost, otherwise the many fibrous roots around the sides will in all probability suffer. I remember such an instance happening on one occasion with Vines for forcing, the after results not being at all satisfactory. Take care of the labels on all young pot Vines where many kinds are on hand, otherwise when planting time comes round some confusion may occur.

ESTABLISHED VINES FOR EARLY FORCING.—Whether these be young canes planted out in the spring, being grown on to form fruiting rods for early forcing, or older Vines previously forced, the pruning should receive immediate attention. To have pruned early in the present month might have been better, perhaps, but such warm weather as we have had, if followed by rain, might have induced them to start too soon. If, however, the partial pruning previously advised was adopted, the final touch, if given now, will be quite in time, assuming that none are started before the date already given. Should they be young Vines, great care will be necessary to guard against exhaustion by bleeding, which these canes, if vigorous, are often predisposed to do. Do the pruning with discretion and run no risks, dressing the wounds as soon as dry. In dealing with older Vines, the pruning should be done in accordance with the circumstances or condition of the Vines in each case. I am no believer in the orthodox system of pruning every spur hard back to the old wood, leaving, perhaps, one or two buds to break when dealing with early-forced Vines. Old Vines in particular will resent this and often break weakly. Instead, therefore, of the close pruning, cut back to the most prominent eye or two; never mind if these be 6 inches or 8 inches from the old spur or last year's pruning point. We grow our Vines for the sake of fruit, not for appearance only; therefore there should be no hesitating to adopt any methods whereby we can accomplish the desired end. Everyone must have noted how well the topmost growths of old Vines will break when the rod is slightly extended; the same thing applies with equal force to the spurs lower down the rods. I strongly recommend this system of pruning for all early-

forced Vines, which are giving signs of having been too severely taxed. It may be asked, Why for early Vines and not others? The answer is, Because the first few leaves upon early-forced Vines, where these are aged, are not always so well developed as one could wish through the root-action being weakly or backward; hence the buds formed at their base are not so good as they should be. It may be urged against this practice that the Vines will become so unsightly, or, in other words, so unlike what one is accustomed to see. This may be so, but it is no valid reason against its adoption, nor is it any obstacle in the slightest degree. If any grower needs to inspect a case before being convinced of the soundness of it in practice, let such an one call and inspect the Vines so treated by Mr. Speed at Penrhyn Castle, and he will there see what he has accomplished. When any spurs so extended reach the top, cut them off and start fresh ones from the base. Vines that are kept for many years closely pruned often lose their natural vigour of growth, hence from this cause alone any system of extension is commendable. If anyone is not convinced of the soundness of this treatment, let him at least give it a trial upon one Vine, letting that one be even the weakest in the house.

AFTER PRUNING.—Let the first operation be that of a thorough cleansing of first the Vines themselves, if insects have given any trouble, and then of the woodwork, walls and pipes, at the same time looking after the state of the glass and putty. Let every nook and cranny be penetrated with hot water, as hot as it can be used comfortably for the hands, such an insecticide as Bentley's soluble paraffin oil is excellent as an addition, taking care not to use it beyond the prescribed strength, then even it will loosen the paint if not washed down immediately afterwards; a very slight amount of scrubbing will then complete the work of cleansing. After all this has been done, see to the state of the inside borders, examining them first as regards moisture, then adding a fresh top-dressing where the roots are upon the surface, in which case there will not be much that can be removed prior to its being applied, but should the top soil appear to be inert, then remove it down to the roots and add fresh in its place. If fresh soil has in the previous year been added, a light surface-dressing of cow manure will now be an excellent change. Then water all such borders thoroughly, more especially near hot-water pipes. Vines that are confined (or thought to be so) will often find a means of egress. To search for these wandering roots is not always expedient, but at any rate, when they are found to exist, they should, if possible, be stimulated in their good work. Outside borders should have received attention before now if in need of renewal, but if a top-dressing is all that is needed it should be applied at once. Here again the same advice applies as that already given. In addition, however, a covering afterwards is needed to conserve the warmth and to prevent the surface-soil from becoming frozen later on. Dry leaves from the Oak or Beech make a good covering, these being kept in position by some stable litter. Do not be led astray as to the state of the outside borders by any rains that may now fall, but make sure of their state by watering them thoroughly before being covered.

MIDSEASON VINERIES. Vines from which all the fruit has been cut should at once have a partial pruning, removing, as previously advised, all the unripened wood first, and shortly afterwards a portion of the rest, so as to leave for the present and until the leaves fall about 1 foot or so on each spur. It should be borne in mind that it is advisable to retain the rest of the foliage, which, until it falls, has its proper functions to fulfil through the receding sap, which undoubtedly assists the latent buds at the base of the leaves. Vines on which a portion only of the crop is now left should have the rest of the bunches cut and afterwards bottled, so that the houses may be thoroughly ventilated, being pruned as previously advised. Any Vines which show indications of not having the wood well ripened should be

assisted by keeping the pipes warm, but never close the house at such times. Many vineries, no doubt, will now be filled with Chrysanthemums, possibly to the detriment of the Vines themselves, first by too early pruning, and then by being kept too warm, to suit some of the Chrysanthemums. These vineries ought rather to be called Chrysanthemum houses, in which Vines are grown as a catch-crop.

LATE VINERIES.—Vines which have a full crop still hanging (or nearly so) will, with the change of weather, need somewhat closer attention. The superfluous wood that is not ripened ought to be thinned out, as it only tends to foster more moisture near the bunches. The pipes should be warmed up every morning so as to thoroughly aërate the houses and dispel the moisture. Check the fires by midday so as to cool down to 50° at nightfall. Keep a close and constant watch for any signs of a berry decaying before it has time to contaminate those around it. HORTUS.

KITCHEN GARDEN.

GENERAL WORK.—Fortunately since my last note we have had some rain, and, though not enough to reach the roots of large plants, the much-needed moisture has freshened up the growing crops, and they are now looking much better. Now will be a good time to go through the various crops, giving the surface a light hoeing, as owing to watering and drought the surface is in a hard, baked condition. This will admit the moisture and promote growth. Many small weeds will now start, the soil being warm and the surface moist, so that land just cleared of crops will soon present an untidy appearance if the hoe is not kept going. There is a lot of work needing close attention. It is useless to leave the old Vegetable Marrow plants that are now fruitless. These, if cleared, will often give space for other plants. Old Pea and Bean sticks, if the crop has been cleared, should be removed, and though in some districts there may not have been much frost, I note in many places owing to drought the plants are over, many having ceased to bear. At this season of the year it will be a good plan to place on one side the stakes good enough for another year's work, getting rid of those that are decayed. Manures will soon be needed in quantity, and these will need turning to hasten decay. I find it necessary to assist fermentation by giving a liberal supply of liquid. This is a good outlet for liquid manure running to waste. Weeds and rubbish may be placed in bulk and mixed with a liberal quantity of lime to kill seeds. I use gas-lime in a fresh state. This mixture is very useful for digging in early in the year when any treading is going on. Now is a suitable time to secure gravel for new paths or to improve old ones. All seed should be cleaned when ready, ripening being facilitated by hanging in a shed or drying under cover.

GREEN VEGETABLES.—The supply is none too plentiful in many parts of the country, owing to the heat and drought of the last few months, and it behoves growers who need a large supply to look well after those plants which turn in after Christmas. With the tender vegetables, such as Beans and Marrows, cleared, there will soon be more demand on the green crops, and to eke out these, if at all short, one may often make use of such things as Celery, Endive, and Cucumbers. Few vegetables if well cooked are superior to Celery, this forming a welcome addition to the supply from now to next April. Endive is not reliable after this month in the open ground unless protected, but with a short vegetable supply it will be well to preserve any breadths not needed for housing for salad by covering these with mats. Cucumbers make a delicious vegetable when boiled. In a short time there will be a good supply from forced vegetables. Seakale, in spite of the drought, has made a free growth this season, owing to the deep rooting of the plants, and where food in the shape of liquid manure was given there is no lack of good forcing roots. I have referred to the deficiency of the

autumn Cauliflower crop, and growers will do well to pay more attention to the early kinds of Broccoli by giving a quick-acting fertiliser to hasten the growth, as the plants are not nearly so strong as usual. This advice is not applicable to the later kinds, as it is not advisable to foster a soft growth with those needed to stand the winter. Autumn Cabbage will continue growing freely for some time, indeed, such kinds as St. John's Day and the Christmas Drumhead, having a dwarf growth with well-protected heads, are little influenced by autumn frosts. The Coleworts this season are a short crop, but with cooler nights I find the quality is improving, and late plantings, though small, will be valuable. To make up for loss of green vegetables in the early spring, it may be well to plant more Cabbage. I have made use of all plants large and small. The larger ones will be useful to eat as greens, in advance of the others.

LEEKs.—These are making more headway, and will this year be very valuable. The early plants will now do with a little earthing up to blanch the stem. Unless, however, they are needed for present use, growth will be stronger by leaving them fully exposed. The Leek is one of our most reliable winter vegetables in a hard winter, and with plants in different sizes there is no difficulty in keeping up a supply well into May. Liquid manure will now be beneficial, and this given weekly will build up stout plants. Fish manure or guano is excellent for these plants if the same be well washed down to the roots. I grow a goodly number of plants on the surface, only using shallow drills. These are useful for soups and flavouring, and save the large ones, which are used for stewing. In heavy soils the food supply may be more varied, and with large plants fit for use it may be well to mould up earlier, as the soil is now in better condition than if too wet.

ONIONS.—Advantage should be taken of wet days to go through the store and remove decaying bulbs. Owing to other work needing attention I have not been able to give this crop the time needed, but if placed thinly in a cool place the bulbs will not have suffered, and in inclement weather it is a good plan to bunch or rope those required to be kept late. I do both, and all are suspended to the roof of a cool shed. Failing a roof, they keep well hung on a wall if given a turn occasionally, so that the air can circulate freely round them. Small bulbs may be kept for present use, and picklers should be placed thinly on shelves till needed for use. Any roots at all soft should not be stored, and those inclined to grow out should be used as required. Winter Onions this season made slow progress, but with moisture they are now growing freely. It will be advisable to give an occasional dressing of soot or a good fertiliser. I notice that mildew has attacked the best plants rather badly. I have checked it by dusting with dry wood ashes and a small portion of sulphur. I observe mildew this season is more troublesome than usual with most of the autumn-sown crops.

CHILIES, CAPSICUMS, AND AUBERGINES.—From Chillies and Capsicums, if there was no lack of moisture, there will this season have been a good return from plants in the open. Plants in the open will not be safe after this date, and it is useless to allow half-ripened pods to get frosted. I remove to a dry house, pulling the plants up by the roots. The pods then colour without shrivelling badly. Even the small green fruits are valuable for mixed pickles. Plants in cold frames will ripen their fruit more quickly if pulled up and suspended in a warm, dry house free of moisture. The Aubergines in the open did well this year, but are not safe now. I am gathering the fruits and placing them in a cool room. Plants in pots will continue to grow if given a shelf near the light and watered sparingly. Fruits on these will swell more freely if the shoots were at all gross are stopped. By having pot plants, a supply may be kept up till the end of the year, when many persons prefer them.

PARSLEY AND MINT.—Parsley was much affected in light soil in the latter part of the summer, and

the supply was none too plentiful. There will be a good supply if the seedlings sown for the autumn supply have been well fed. The plants delight in the cooler nights, with heavy dews, and if occasional supplies of soot or liquid manure can be given before frost checks growth, there will be a good return. I am much later than usual in lifting the plants for the winter, owing to growth being so much later. A goodly number of the plants intended for lifting will now be covered with frames in their growing quarters. Seedlings sown late will benefit by being thinned, and after doing the work it will be well to give the plants left a dressing of soot, doing the thinning in showery weather. Mint intended for forcing should now be cut over as close to the soil as possible, and a small portion placed under glass. I find boxes the best for a small, early lot. For a larger supply I place roots in front of a vinery or Peach house started next month, covering with light soil and watering freely. Plants in borders needed for early supplies in the open will now benefit by being cut over, cleaning the surface and giving a good dressing of light manure. S. M.

ORCHIDS.

PAPHINIAs.

THIS is a very interesting, if not particularly showy, genus, and one that is well worth growing. There are not many species, and these are all natives of different parts of South America. The plants should be grown in an intermediate house, and being of a rather small habit, it is important that the atmospheric conditions be kept as regular as possible, and no alternations of drought and moisture, cold draughts or insulcious air be allowed, for all these are very injurious to the tender foliage and apt to bring a plague of insects in their train. Paphinias, more than most Orchids, are subject to insect attacks; hence this care with the atmosphere; but this will not be sufficient of itself, and frequent fumigations and sponging will be necessary as well. The plants are epiphytal, and as the flower racemes are mostly pendent, the smaller pans or shallow baskets make the best receptacles for them. The base of the pseudo-bulbs must not be buried; it is better to elevate them a little, but they need not be kept very high. The crooks for drainage may come up nearly to the rim, only a very thin compost being needed, and, as the roots of these Orchids are very liable to injury through the material being sour, it is best to add more hard material, as crocks and charcoal, than usual. When the very best of peat is used, the plants go on for a couple or even three seasons without any renewal, but this description of peat seems to be getting scarce, and many of the samples sent out by dealers are not first-rate by any means. Surface dressing is not, as a rule, advisable, or only to a limited extent, for when such a thin compost is used, most of the roots are naturally close to the surface and easily injured. When repotting, take every bit of sour material away, but if there are a few of the newer roots in the upper part of the compost healthy, let these remain, and they will save the plants from distress to a certain extent. A moist atmosphere is always essential, especially after repotting, and it is then that light dewings overhead are desirable.

PAPHINIA CRISTATA, the best known species, is a dwarf plant with pseudo-bulbs each about 1½ inches high, the leaves about 8 inches in length on strong plants. The flower-spikes bear about three flowers, the sepals and petals of which are yellowish shaded brown, the lip deep chocolate-purple and of very peculiar structure. There is

a variety of this species having pure white flowers with the exception of a yellow marking on the lip. Great care is necessary in shading the house for this species, for the leaves are so thin in texture that, although they like plenty of light, they are easily damaged by direct sunshine. It is a widely distributed plant naturally, not only on the mainland of South America, but also on some of the islands adjacent. It was first imported from Trinidad in 1834.

P. GRANDIS (*grandiflora*) is a very handsome species, also dwarf in habit, and bearing richly coloured flowers. These occur on three flowered spikes, and have the sepals and petals creamy white, with irregular bars and markings of deep chocolate-purple. The lip is yellowish and dark purple, the blade being covered with greenish white hairs. This is occasionally imported from Jamaica and different parts of South America, the first occasion of its flowering in England being in 1883.

P. RUGOSA is a good deal like *P. cristata* in habit, and is an uncommon species discovered in New Grenada in 1876, but not introduced to this country until a few years later. It bears pendent scapes, the individual blossoms being about 4 inches across, pure white, with spots varying in colour from bright red to dull purple. The lip is reddish purple, with a tuft of white hairs in front. This also requires a rather dense shade and more warmth than any other kind.

Cattleya Gaskelliana picta.—A very fine form of this useful *Cattleya* under this name is now in flower. The blossoms are large, of a pretty rose on the sepals and petals, the lip having a finely-coloured blotch almost as deep as in the best varieties of *C. Trianae*, which it somewhat resembles. The plant is of strong, vigorous habit, and at first sight with its broad foliage looks a good deal like *C. Warneri*. The plant was purchased at a sale in the neighbourhood some two years ago, and missed flowering last season.

Odontoglossum grande superbum.—This fine variety well deserves its name, the blossoms being very large and brightly coloured, and produced rather earlier in the season than those of the type. A fine plant of it opened its blossoms on September 20, but this is not earlier than usual. There is little difference in this and the type regarding the disposition of the colouring, but it is like a very large edition of it, and all the segments are broad and of great substance. It is a species that cannot be too highly recommended to gardeners or amateur growers.—H.

Cattleya Schofieldiana.—This is a useful and pretty *Cattleya*, and I have noted it in flower in several collections. The sepals and petals are yellow, spotted with crimson, the downy lip rich purple, fading to white. It must be as strongly grown as possible during the earlier part of the season, large plants requiring good root room. The flowers appear on the apex of the growth, and when these are over a lowering of the temperature and rather less moisture serve to keep the eyes dormant at the base of the stem like bulbs. The usual *Cattleya* house temperature suits it well, and the compost—peat and Moss—must be rough and well aerated.—H.

Cypripedium Ashburtoniæ.—Though one of the oldest of hybrid kinds, this is still a useful and fine plant that one cannot well have too many of. The better varieties are well worthy of extended culture, such kinds as *C. A. expansum*, with its immense dorsal sepal, or *C. A. majus*, one of the most healthy-growing *Cypripediums* in existence, being far before many of the newer and very expensive species and hybrids. It is a cross between *C. insigne* and *C. barbatum*, and was first raised by Mr. Cross when gardener at Melchet. It does well in the ordinary plant stove or in an intermediate Orchid house treated as advised for *Cypripediums* generally.

Pleione lagenaria.—The earlier plants of this useful species are already in flower, and very

bright and pretty at this dull season. The largest flowers are each 3 inches across, rosy lilac on the sepals and petals, the lip marked with rich purple. In a house kept a little warmer than the *Odontoglossum* house proper this species thrives well, and when in bloom is arranged with small Ferns, as its own foliage falls as the flowers open. It blooms from the base of the bulb and should be repotted directly the blossoms are over, reserving only so much of the old roots as is necessary to hold the pseudo-bulbs in position. Peat, loam and chopped Sphagnum Moss are the best compost.

Vanda tricolor planilabris.—The better varieties of these large growing *Vandas* are very beautiful plants, and this is a very pleasing form. The colour of the sepals and petals is variable, but it is usually of a yellow tint, more or less heavily spotted with reddish-brown. A large plant recently noted with two fine flower spikes was very beautiful, each of the spikes carrying a dozen flowers. The plant is easily cultivated in an intermediate house, and should be given large pots or baskets, so that the long air roots may find their way eventually to the compost. The best time to repot is in early spring, keeping the plants a little closer and warmer afterwards, and watering with care until new roots are formed.

Mormodes buccinator.—I think it would be very difficult to name an Orchid with a greater variety of colour in it than is present in this pretty species. Not only is the number very large, but the colours are beautifully contrasted, making a most interesting flower when carefully looked into. The spikes grow erect from the base of the rough-looking pseudo-bulbs, are about a foot in height and many-flowered, the ground colour of the sepals being yellowish with crimson spots, the lip a combination of green and white and of the peculiar form seen in this genus. Its culture is simple, a light position in a moist, warm house suiting it well as long as it is growing, keeping the roots well supplied with water. It likes a complete rest after the leaves have fallen, and must then be kept quite dry.—H. R.

Oncidium flexuosum.—None of the branching-spiked species of yellow-flowered *Oncidiums*, beautiful though many of them are, can compare with this grand old species for cutting. The contour of the spikes is more graceful than that of any kind I know, even the small side branches having an elegant appearance, only partly shared by such as *O. pulvinatum* and similar kinds. The culture is simple; the plant is cheap and plentiful, and as it will grow and flower profusely in ainery or ordinary plant stove, it ought to be grown in every garden. I saw it used very effectively at a local show not many weeks since. The lower part of an epergne and several small specimen glasses were dressed with *Anthurium Andreanum*, and the *Oncidium* was used with good effect among the spathes, standing well above them and giving all a light and airy effect that could not be had by any other means. If I were tied to a dozen varieties of *Orcids* useful for cutting, this beautiful old *Oncidium* would certainly be one of them.—H.

Phalænopsis violacea.—It would be difficult to name a more generally useful yet beautiful Moth Orchid than this, and the fact was strongly brought to my notice when visiting a neighbouring collection recently. Here was a nice batch of the species imported a few years since, and among the plants in flower was considerable variation, one plant coming very near the rare and lovely albino form, *P. violacea alba*, so seldom seen. Not that this is any more beautiful than a good form of the typical plant, for the pretty violet-purple tint on the lower sepals and lip gives life and brightness to the flower, and when a good spike is seen the effect is very fine. Those who are in the habit of exhibiting groups of stove and greenhouse plants often find a difficulty in getting enough *Orcids* to give the group that character which only these plants can

impart, and this species may well be recommended to such, its bright and telling appearance being a great help at this season. It is not difficult of cultivation as *Phalænopsis* go, and the treatment advised for the genus as a whole will suit it admirably.

Burlingtonia granadensis.—This is distinct in habit and a pretty, small-flowered kind, the racemes bearing about half a dozen white flowers stained on the lip with yellow. These are pendent, and when well flowered the plants have a very pretty appearance with the racemes hanging round the baskets or pans in which they are grown. These form more suitable receptacles for them than pots on the stage, as only a little compost, and that of good quality, is needed. The cool end of the *Cattleya* house suits it well, and the atmospheric moisture should be kept as regular and constant as possible, these small growing *Orchids* being easily incommoded by alternations of drought and moisture or heat and cold. Although not a large-rooting plant, it likes an abundant water supply when grown in these small receptacles, the roots interlacing and growing one over the other, occupying every bit of compost and drainage, and often pushing roots out into the congenial atmosphere. The growing and resting seasons are not very clearly defined, and, as a matter of fact, watering depends more upon the state of the weather and external atmosphere than the growth. The plant is a native of Pamplona, in New Grenada, and was discovered by M. Linden in 1842, but not introduced to cultivation for many years afterwards.

NOTES ON ORCHIDS.

THERE is plenty of finishing growths now, and the more sunshine and light allowed the better. In the warmest house many of the *Dendrobiums* are finished, and a few have already been taken out. *Catasetums*, *Cyanoches*, *Mormodes*, and other species of this class must be brought right up to the glass, and the removal of the *Dendrobies* will facilitate this. All the New Guinea *Dendrobies* must be kept warm now, more especially those that are pushing young growths. Keep the *D. Phalænopsis*, *D. bigibbum*, and similar kinds right up until the flowers are open, as the full light has a certain bearing upon the colour of the blooms, but when fully open the plants may go to the flowering house or to a cool, shady structure where there is not too much atmospheric moisture. Here they retain their freshness over a long season. The *Catasetums* may, if flower-spikes show, be well moistened and kept warm, but it is imperative that as soon as the flowers are over the plants be placed in the full sun either out of doors or close up to the roof-glass in a light house. It is different with *Aerides* and *Saccolabiums* growing, perhaps, in the same house. These, of course, like a resting season, but the conditions during growth and rest are not so widely different as are those needed by the pseudo-bulbous kinds named. As long as the hot weather lasts they will probably keep growing, but when cooler conditions occur the roots will soon begin to cloud over at the points, and after this a greatly diminished water supply must be gradually brought about. *Deciduous Calanthes* will by this time be able to stand the full sun, provided they have been gradually inured to it by slightly lessening the shading. In any case the more sun they get the better, as it hardens the pseudo-bulbs and foliage. No liquid manure or other stimulant is necessary after the buds begin to show on the flower-spikes, and it is still necessary to exercise care in watering about the base of the spikes. When the flowers show colour little or no water will be needed, and while the foliage is going off keep the plants turned occasionally to allow of the sun reaching all parts of them. The more sensitive *Phalænopsis* and *Anæctochili* must not be forgotten when the other plants are beginning to be rather hardly treated. A separate compartment should, of course, be set apart for these where possible, but if grown in the same house as those named

above they must be arranged in the warmest and shadiest position. As yet no fire-heat has been necessary, but as October draws on a little warmth will be allowed, not so much to keep a high temperature for exciting temperatures at night at this time of year are dangerous—but to make the air in the house more buoyant and allow of free ventilation by night and day. From 60° to 65° at night is quite high enough for this house where the growths are finishing.

The Cattleya house is getting very interesting, and will now continue to do so as the autumn-flowering kinds come in. The beautiful *C. aurca* is in good condition now, and there are still a few late flowers of *C. gigas*, *C. Gaskelliana*, and *C. Eldorado* of the *labiata* group. Among the taller-growing kinds, the prettily-tinted *C. bicolor* is always welcome, while *C. Scholfieldiana* in its better forms is a very fine thing. Many of the hybrid forms having *C. Loddigesi* as one of the parents are flowering now or just going over, and there is a strong family likeness in all these. There is still ample time to repot any Cattleyas that need this attention—*C. Eldorado*, for instance, and even *C. Bowringiana* if the growths seem inclined to root. Late plants of *Laelia purpurata* and *L. elegans* may still be put in order, but such as *L. superbiens* and the *Schomburgkias* ought not to be potted about now. Water all these very freely where pushing their flower-spikes, and the latter especially may be encouraged by a little more warmth if the spikes do not seem to move freely enough. In a house not kept well up, such a species as *S. tibicinis* sometimes refuses to open its blossoms at all, and the strength of the plant is simply wasted on the production of a long barren spike. After the blossoms are past, place the plants in a cool, light house and decrease the water supply considerably. All this class of plant must by now be very nearly exposed to the full sun, only lowering the blind for an hour or two in the middle of the day, but *Vanda suavis*, *V. tricolor*, *Cologynis* of such kinds as *C. speciosa*, *C. barbata*, *C. cristata*, and others should as yet be more closely shaded. *Mittonia spectabilis* and its many varieties must have a little shade, or the foliage will suffer, but the less applied the better. All the species of *Laelia* in the Mexican house may be fully exposed to the sun, but if such kinds as *Odontoglossum grande* and *O. Inseayi*, *Vanda Kimballiana*, and others are included, the shading must be carefully managed; on the one hand not to injure the latter kinds, on the other to allow the greatest possible amount of light to the *Laelias*. Here the temperature may run up fairly high in the daytime, but from 50° to 53° is ample by night, and all the air possible must be kept on. Owing to repotting operations in the cool house, the shading must be well attended to now; but when the plants are again established, allow as much light as is consistent with a day temperature of about 60° to 65°, 50° being ample by night.

Habenaria Susannæ.—Where there is enough heat at command the *Habenarias* are very interesting. This species is exceptionally so, the tall spikes of white flowers, with the pure white lip cut up into long filaments, being very distinct from anything now in bloom. The spikes on strong plants are 18 inches or more in height, leafy, and each spike bears about three flowers. The plants should be grown in the East India house, in a compost such as suits terrestrial Orchids generally, equal parts of loam, peat, and chopped Sphagnum Moss, with abundance of finely-broken crocks and charcoal. The most frequent mistake in the culture of *Habenarias* is drying the roots too much in winter, yet there is a danger of the root-stocks decaying if kept in the soil and watered as usual. Many successful growers are in the habit of crushing charcoal and crocks, placing the mixture around the roots when potting. It keeps them clean and fairly moist without being stifled, so to speak, by the closeness of the compost. A shady position in a warm, moist house should be chosen, and light dewings over the foliage help to keep this in order and

insects in check. *H. Susannæ* is a widely-distributed plant, naturally occurring on the islands about the Malay Peninsula and also low down on the Himalayas. It was introduced about 1833.

ACINETA BARKERI.

This, the species illustrated in the accompanying cut, is a very fine Orchid, and it is a great pity that this genus should have gone so largely out of cultivation. Collectors seldom send *Acinetas* home, and when they are offered there is no great rush for them, while Cattleyas, *Odontoglossums* and other more popular kinds are very eagerly bought up. It is this continual duplicating of well-known kinds that makes present-day collections of Orchids far less interesting than they used to be, for on visiting nine places out of ten during any one week one comes across the same species and varieties in

Acineta Barkeri.

them all. This beautiful plant bears long pendulous racemes of golden yellow flowers, each marked with a bright red spot on the lip, and during the whole of the time it is in flower it emits a very pleasant fragrance. The foliage and bulbs are of a deep green when the plants are healthy, and they are very attractive even when out of bloom.

The culture of *A. Barkeri* is not very difficult. The plant is rather a strong feeder for an Orchid, so the compost must be substantial. Owing to the direction taken by the spikes, baskets or some other receptacle that may be suspended from the roof must be chosen, and well-placed drainage is essential. Use equal parts of peat, loam fibre, and chopped Sphagnum Moss for compost, adding thereto plenty of roughly

broken charcoal and crocks to ensure a free passage for the water. The roots delight in this open, yet substantial medium, and it is a noteworthy fact that good fibrous loam not only does not sour quickly, but it seems to have the effect of keeping the peat in a healthier state. A frequent mistake in the culture is to be always pulling the roots about. These, if healthy, are longer-lived than those of many Orchids, but, being of a thick fleshy nature, are easily damaged. It is all the more necessary, then, to do the rebasketing thoroughly, and to make sure that nothing sour or decayed goes into the new basket. Keep the plants up a little above the level of the rods, as unless this is done the spikes are occasionally injured. After basketing healthy plants, no trouble will be found in getting the roots to start, but should they seem slow, moisten them only very slightly until they become more active.

If roots are really plentiful, it is surprising what an amount of water is needed while growth is going on. No Orchid, in fact, requires more, but to water a compost containing but few healthy roots is wrong. It silts the finer particles down among the drainage and fines down the peat, making the whole sour and unsuitable for the roots when they do appear.

Plants that are in really a bad state at the roots would be far better shaken right out of the pots and laid on a moist stage until new roots appear. I have seen this Orchid very successfully cultivated on flat blocks of wood placed horizontally and given an inch or so of compost. It is a good plan, but apt to lead to a lot of trouble in watering. While at rest the moisture will naturally require to be somewhat lessened, but here it is well to be on the safe side, for anything approaching shrivelling will in all probability be followed

in the ensuing season by weak and badly coloured foliage, while many of the older leaves will often drop in spring. The East India house is not too warm for the plant provided plenty of atmospheric moisture is present. During the early part of the season especially, shading is very necessary, for the foliage is exceedingly liable to injury when young and tender, though liking abundant light and air later in the year. *Acineta Barkeri* is a native of Mexico, where it was discovered in 1837.

Odontoglossum citrosimum.—Knowing how many fail to flower this Orchid, I thought the experience of Mr. Simon, gardener to Mr. Ravenswood, Bexley, who so successfully cultivates it, might be of interest to some of your readers. The following is the treatment given to

his plants: They are put into baskets and pans in Orchid peat, with Sphagnum Moss on the surface, suspended from the roof of an intermediate house, and dipped in water when the Moss looks a little dry on the top. During the growing season great care is taken not to wet the young growths when dipping the plants. When they have finished their growth, water is gradually withheld until they are quite dry. They remain so for four or five months until the flower-spike shows. The plants remain in the same house all the year.—J. CARVILLE.

FLOWER GARDEN.

ANTHEMIS STYRIACA.

The accompanying illustration very clearly shows one of the best of composite plants, though, unfortunately, one also of the shorter-lived section of these flowers. In its flowering the plant is usually so profuse that it dies when the blooming is over. The illustration shows a large group of the plant, which flowered in the rock garden at Kew during the early part of the summer of this year. The plant is best

Anthemis styriaca. From a photograph by Mr. J. Gregory, Croydon.

regarded as a biennial, and when afforded plenty of room will produce a rather close spreading tuft of somewhat silvery leaves, soft and woolly to the touch. As may be gathered from the picture, the blossoms are large and pure white, the heads being borne singly on the stems, which reach to 9 inches or thereabouts in height. The plant flowers for a long time during late spring and early summer. Some authorities consider it identical with *A. carpatica*, but for garden purposes the two are sufficiently distinct. E. J.

Salvia splendens grandiflora in the open.—Quite large bushes of this glorious plant can be seen in bloom in the open ground at Gunnersbury House. They are in a somewhat sheltered spot, but despite heat and drought they have flowered with remarkable freedom and still are doing so. The brilliant scarlet colour gives a striking hue during the gloom of the waning summer days. Mr. Hudson finds the best way to propagate this plant is by means of seed, as plants so obtained bloom so much better than those reared from cuttings. Out of doors the flowers appear to take on a more brilliant tint than under glass, and the size

of the inflorescence is equal to that on house-grown plants. R. D.

Zauschneria californica. This is again flowering grandly this year, the autumn drought and heat suiting it well. If those who complain of the plant running wild and giving but few flowers were to plant it at the base of a sunny wall, confining the roots to rather poor soil and using ample drainage, they would find that it would not encroach much on its neighbours and would flower magnificently; indeed, it is surprising to see such a continuous supply of bloom from such little growth. I find it very easy to propagate either from cuttings, which must not have much water, or by division. A little care in dividing is necessary, as the root-stalks are very brittle, but, on the other hand, the smallest bits will grow. It can be happily placed in crevices on the upright portions of a rock garden, and in the extreme west of England, where the fences are built up with sods and faced with vertically placed thin stones, gorgeous effects would be possible by planting it freely between the stones.—CORNERIAN.

Helianthus lætiflorus.—Though the flowers of this are not so chaste in form as those of some others of its relatives, notably that lovely form of *H. rigidus* named Miss Mellish, the plant has such

grown and those which are allowed to remain unlifted year after year. L. P. G.

VIOLETS AND HOT WEATHER.

Mr. Crook's note (p. 211) is particularly welcome after such a dry season. There are various opinions as to the position best suited for the summer growth of Violets, and I must say that after a good many years' experience I do not agree with those who advocate an aspect fully exposed to the sun, as the plants as a rule do not receive the attention Mr. Crook bestows on his plants. I mean in the way of mulching and constant syringing, which are absolutely necessary in seasons like the present if the curse of the Violet grower (red spider) is to be kept at bay. The idea that exposure to hot sun in order to mature the crowns and ensure a good yield of bloom is, I think, more imaginary than real. I prefer a position in which the plants get the benefit of the sun for a few hours only in the morning. It may be thought that plants grown in hot quarters stand the winter better, not suffering so badly in damp or foggy weather, but I have never had any great difficulty in that respect provided the plants were well grown and the foliage stout and leathery and regular attention to surface-stirring and airing given. It is the poor, flimsy, half-starved plants that succumb during the winter months. Of course there is not the risk of partial failure from growing the plants in the open where the subsoil is cool. Mr. Allan's Violets at Ganton generally occupy a north border throughout the summer months. Mulching and syringing, as mentioned by Mr. Crook, are two important points in summer management, and where the garden engine cannot be conveniently got to the plants, a hose should be employed so that the water plays with force on the underside of the foliage, that being where the pest secretes itself. Mere sprinklings overhead with an ordinary syringe or watering-can may be practised and spider thrive nevertheless. When on the subject of Violets, I may mention that a friend of mine whose Violets were diseased obtained from me a fresh stock of runners. Amongst other sorts I sent him some of Lady Hume Campbell. To my surprise, after they had flowered, he informed me that the latter was simply *De Parme* under a fresh name, a variety he had grown for years. I have always thought them distinct, but perhaps some other gardeners will give their opinion. J. CRAWFORD.

NOTES AND QUESTIONS.—FLOWER.

Lobelia Carmine Gem.—This can now be seen in full beauty at Gunnersbury, several plants forming a central group in one of the flower beds. What strikes one is the freedom and continuity of bloom shown by the plants. In addition to throwing up a strong central stem, the plants put forth many side ones. Not long since it was given an award of merit by the floral committee of the Royal Horticultural Society, when exhibited by Mr. W. Bain, from Burford Lodge Gardens. R. D.

Begonia Corbeille de Feu.—This very free-flowering Begonia, one of the *ascotensis* type, deserves notice for its value for growing under trees. Mr. J. Hudson has in Gunnersbury House Gardens two beds of it under the heavy shade of tall trees, where it is full of bloom and apparently quite as free as in the open. Around it there are several types of the zonal *Pelargonium* without a truss of bloom on any of the plants. We have but few flowering subjects which will do well under trees, and this Begonia is one of the best of them.—R. D.

Dahlia Rising Sun.—Despite their showy blossoms, all the Dahlias are not suitable for planting in a bed or mass, but this is one that can be recommended for the purpose. It reaches a height of about a yard, or sometimes a little more, while the large and full, but not particularly lumpy blossoms are of a rich scarlet colour. Occasionally tipped flowers will be produced, but they are not sufficiently numerous to be taken into consideration. Altogether this Dahlia forms a bright and effective bed, the flowers standing well up above the foliage. H. P.

good and distinct qualities as to make it very valuable at this season. Perhaps its greatest claim to notice is its lateness in flowering, it being a contemporary of that other valuable hardy plant, *Pyrethrum uliginosum*, and just now these and a few of the *Michaelmas* Daisies are the finest flowering plants in the outdoor garden. Under good culture it grows about 8 feet high and bears twenty or more flowers on each stem. It is very useful for cutting to fill quite large vases, and lasts longer in water than any other perennial Sunflower that I know. The flowers are deep rich yellow in colour, the disc brown when the flowers open, and changing to yellow as they become fully developed. The petals are irregular in number, averaging from fifteen to twenty; the stems brownish purple, slender and wiry; the leaves deep green, fullest at the middle, narrowing to a point at each end, and borne thinly in pairs. The plant is an aggressive and persistent grower, spreading underground and coming up year after year from the thong-like roots, but this is of little moment, as to grow both it and all of its class well the strongest single crowns should be taken up yearly and replanted on a fresh piece of ground or on the same site after clearing it of surplus roots and manuring well. There is no comparison between the plants so

INDEX TO COLOURED PLATES.

The following is a list of Plates that have appeared in "The Garden" up to the end of the Fifty-Second Volume, ending December 25, 1897.

ORCHIDS.

ODONTOGLOSSUM HARYANUM.

DURING the ten or twelve years that have elapsed since the late Mr. Horsman, of Marks Tey, imported this fine species it has rapidly advanced in favour, and is now one of the most popular of Orchids. It is also one of the most distinct and beautiful, the disposition of colour being unusual in the genus. From a pale green pseudo-bulb it throws up tall semi-erect scapes of flower, these varying somewhat in size and colour. Good forms have the blossoms each upwards of 3 inches across, the ground colour of the sepals and petals chocolate-brown, irregularly streaked with bright yellow. The latter have in many cases a large white area at the base, this being lined with bright purple. The lip is principally white, lines and bars of purple radiating from the centre, where there is often a fine yellow crest. It is a Colombian species, and therefore does not require any great amount of heat, but I have always found that newly-imported plants for the first season, or even two seasons, make a far better growth and larger pseudo-bulbs in a house kept nearly as warm as the Cattleya house. They get a better hold upon the compost, and this is very important, for unless an Orchid takes with a will to its adopted home the first season or two the probability is it never will.

O. Haryanaum is not a difficult species to grow when well established, but it is always well to keep it healthy, for once out of health it is difficult to bring it back again. Often fine plants have been ruined by overflowering, the plants being allowed to perfect and carry the large, vigorous spikes that are produced from healthy plants before they are properly established. It is not always they do so, and the probability is that a good deal depends upon the time of year the plants are collected. Often newly-imported plants push up poor spikes, but these do not distress the plants much, and the

latter go on and increase in vigour annually; whereas a fine healthy plant may throw up a large spike which, if allowed to remain on until it fades, will paralyse the growth of the plant, so weakening it that years of careful culture are necessary to bring it round. Far better cut the spikes as soon as the flowers open, or even pinch them out and let the plant gather strength before flowering at all. It is always best and cheapest in the end to purchase fairly strong and large plants of this species, for though the small bits sometimes offered seem remarkably cheap, they are not really so, and they will be many years before they reach flowering size, if ever they do. Being a fairly free-rooting species, the pots may be of medium size. The best material should be used for potting, equal parts of peat fibre and Sphagnum Moss being a good mixture. Place this thinly and firmly, with plenty of finely broken crocks over free drainage. Plants well potted will remain two years, or even three, without needing any further disturbance, so room may be left for two years' growth at least before the bulbs reach the rim. O. Haryanaum requires ample moisture when well established, and as soon as the roots have taken a firm hold and one pseudo-bulb has been made, the plant may go to a rather cooler house. Such an one as suits O. grande and O. citrosimum will do it well. Not only the roots, but the head of the plants must be kept moist while growing, and for this reason light dewings from the syringe are very helpful in dry, hot weather. In no case must the least sign of shrivelling take place, this being very weakening to the plants and leading to small growths and puny flower-spikes. Less moisture is needed, of course, when the plants are at rest, but as they are not very constant in their time of growing and resting, no exact time can be laid down. A plant resting in autumn would naturally need more water than when resting in the middle of winter, while by the same token, a growing plant in winter needs more care in watering than when growing during the summer months.

VANDA CERULEA.

THERE is not among the many fine species flowering at this dull season of the year a more striking Orchid than *V. cerulea*. Its azure-blue flowers are always admired, either on the plants or when cut. It is usually considered a somewhat difficult plant to keep in good health for many years after importation. It grows freely enough for the first two years in almost any position, but it is generally after that period that any difficulty is experienced. This difficulty may be overcome with a little forethought. I am afraid that the too liberal supply of water and high temperature we so often give the plants during the resting season must account for the destruction of the majority of the plants that are imported annually. Is it to follow that, because this is an evergreen species and coming from the Khasia Hills, its requirements are met by keeping the plants in a growing atmosphere throughout the whole season of the year, and thus attempting to induce unnatural growth? In my opinion this is one of the greatest mistakes made in its culture. I find that if the plants are treated with due consideration during the resting and growing seasons there is no Vanda that gives a better return or is less difficult to manage. I usually add some Moss to the plants in March, when they are removed from their winter or resting quarters into the East India house, where they are suspended near the roof glass in baskets. They get a good watering as soon as they have been attended to, after which they are kept in a reasonably dry condition until growth and root action set in. Then the plants are liberally supplied with both atmospheric and root moisture, which is continued right up to the time the flower-spikes appear and continued until the blooms have been removed. The plants are then gradually worked into cooler quarters and a drier condition of the roots is maintained. One of the best positions that can be given during the resting season is a vinery where there is always a free circulation of air and from which frost is excluded. The watering will be the principal item to be considered. Especial care is required in dull, cold weather, for the least excess of moisture at the root during such conditions is liable to cause the dreaded black spot on the foliage. This Vanda does not produce its

flowers satisfactorily in the London area, owing, no doubt, to the dull, smoky atmosphere to which we are subject. The flowers do not come nearly so fine in point of colour as we see them in a purer atmosphere and under favourable conditions. I have had flowers of what I have known to be exceptionally fine varieties come almost paper-white when the outside conditions have been dull and sunless. H. J. C.

Epidendrum inversum.—The pretty whitish and purple flowers of this species make it worth a place in all collections where variety is looked for. The plant is easily grown, and if properly treated flowers freely enough, though it is not unusual in some places for it to remain year after year without showing a flower-spike. This is owing to giving too much heat and moisture and insufficient light after the growth is made up, for it is as fond of light and air as are the evergreen Dendrobiums.

Miltonia Lamarckiana (*M. candida* × *M. Clowesi*).—This is a natural hybrid. The sepals and petals are deep brown, barred and tipped with bright yellow, with some purple at the base. The front half of the lip is pure white, with a broad blotch of purple in the centre. There are several prominently raised ridges at the base, white, shading to purple. The habit of growth has the intermediate character of both the parents. A plant with two spikes of flowers and buds was recently exhibited at the Drill Hall from Sir T. Lawrence's collection.—S.

Cypripedium Leeanum.—This lovely hybrid is still one of the very best and most showy. The fine dorsal sepal has a small bright green area at the base, from the centre of which a line of spots reaches nearly to the apex, the rest of the segment being pure white, the lower part having many small purple spots. The petals are yellowish, streaked with brownish purple, wavy on the edge, and the pouch is yellowish brown. The plant is one of the best growers and thrives well in an intermediate house. Its parents are *C. insigne* and *C. Spicerianum*, the original plant having been raised in Messrs. Veitch's nursery, where it flowered in 1884.

Lælia Dormaniana.—The habit and flowers of this *Lælia* are quite distinct from those of any other, and apart from this it is a pretty species that ought to be freely represented in all collections of Orchids. It is not of the strongest constitution, but still with ordinary care it may be induced to grow satisfactorily and flower freely. It should not be given too large a pot, for the roots, though fairly fleshy, do not seem able to push through a great thickness of compressible compound. The ordinary *Cattleya* house temperature suits it well, and no special treatment beyond careful watching of its growth and resting seasons is necessary. The flowers are a brownish or olive tint in the sepals and petals, these being marked purple, the lip bright rose and purple, an effective bit of colouring.

Lælia anceps Schreöderiana and Schreöderia.—In "H. J. C.'s" note on *L. anceps alba* (Oct. 15, p. 296) he refers to this variety in Mrs. Lea's collection at Parkfield as *Schreöderia*. I have no doubt it was but a slip of his pen, but as there are yet many who are not aware that the difference in termination of the specific adjective entirely alters the case, and means two varieties, very distinct from each other, it will be as well to refer to it ere the *anceps* season commences. *L. a. Schreöderia* is a dark form of good proportions with a very dark small lip; its petals and sepals have dark tips, shading to light rose at bases. *Schreöderiana* is a white form that came with *Stella* and *Sanderiana*. It is pure white everywhere with the exception of the crimson lines in the tube of the lip and the pale yellow ground colour on which they are pencilled; its lip is large, broad and flat. This description will read the same as that for *Stella*, and in colour there is no difference. The distinction lies in form. *Stella* has a long-stalked lip, an extension of the ordinary dark *anceps* lip. *L. a. Schreöderiana* has a very

broad, almost oblong ovate lip, with no stalk to it. Moreover it has the peculiar overlap of the side and front lobes at their junction more marked than in any form of *anceps* I ever saw. Having studied *L. anceps* specially, I can fully appreciate how easily mistakes may be made by those who only superficially observe the many forms that have been named. It would have been far better had Reichenbach not named *Sanderiana* as a species. Had he called it *Dawsoniana* var. *pacifica* (it comes off the Pacific or western slope of Mexico) he would have done better, as no one who looks at the two can find out any difference which is enough to make another species of it. It is only a geographical form of *Dawsoniana*. There are those who rely on the shape of the latter to make it distinct from the former. Is not a bad form from *Fusagamga* as much *Odontoglossum crispum* as a fine form from that very elastic place, Pachó?—DE B. CRAWSHAY.

NOTES AND QUESTIONS.—ORCHIDS.

Odontoglossum Schreöderianum.—On page 297 "Stelis" mixes two distinct plants in one name. The *Odontoglossum* is a supposed hybrid found in Colombia, thought by Reichenbach to be between *O. tripudians* and *O. Pescatorei*; it is a unique plant in Baron Schreöder's collection. The *Miltonia* comes from Central America. Under *M. Schreöderiana* in Veitch's "Manual of Orchids" this prevalent error is pointed out. Both plants are recorded there in proper positions.—DE B. CRAWSHAY.

Dendrobium Parishii.—This variety is quite unsuitable for pot culture on account of the horizontal character of its growth. If small plants in pots are stood near the pathway, they are almost sure to come to grief if knocked by the hand or coat. The best receptacle for them is a basket or pan, this being suspended from the roof. I have found that it requires thorough ripening ere it will flower at all freely. I once had a plant which for years refused to flower when given the usual *Dendrobium* treatment. At length I placed it as soon as growth was completed in a Pine stove and gave it a thorough baking. The following spring it bloomed.—J. C. N.

FLOWER GARDEN.

FORMING A BOG GARDEN.

I HAVE a shady corner at the angle of north and west walls at the end of a lawn. I want to make a bog garden of it. There are about 4 or 5 square yards. How shall I go to work? Is it necessary to put in a cement bottom? The soil is rather stiff and retentive.—A. E. GIBBS.

* * * The position named appears a capital one for the suggested bog garden, and with a selection of suitable plants could be made a most attractive spot. The "shady corner" referred to will accommodate many good things, though a shady place is not an absolute necessity, so far as life is concerned, but it is material in the prolongation of the flowering subjects which, in every garden, it is desired to retain as long as possible. There is no food for plants in a cement bottom, there is no drainage, and unless the drainage is made accurately a possible stagnation of the whole is neither improbable nor impossible. Moreover, it is an added expense, from which no adequate return is likely to ensue, and it may, therefore, be dismissed altogether from the subject. As no idea is given concerning the moisture supply, I take it such is forthcoming either as an overflow from an adjacent fountain basin, or it can be laid on and, therefore, placed under control. For present purposes I will assume it is under control. This being so, "A. E. G." may go to work in the following manner: Excavate the original soil for the space of two-thirds of the whole area at disposal to a depth of 2 feet, sloping the remainder to the sides all around in such a way that the shallowest portion could be given 8 inches or 9 inches of prepared soil, and allowing that the surface-level of the bed shall be 4 inches or

6 inches below the ordinary surrounding level. In this way the rainfall is secured and is often helpful. A moderate firming when in a moist state will make the bed sufficiently secure for retaining the moisture. In the lowest part of the bed, 4 inches to 6 inches of clinkers, broken pots, &c., may be placed for the sake of drainage, and, if possible, a slow drain may be also connected therewith to take superfluous moisture. This to some may seem a sort of contradiction to the term "bog," which naturally is more or less always of a swampy nature. The artificially arranged bog bed differs from the swamp or bog in nature, chiefly by devoting acres to perhaps a solitary species or genus, whereas the artificial bog is an endeavour to grow in a few yards some fifty or more species, all more or less moisture-loving, but not in the same degree. Experience, too, has shown that artificially supplied moisture is best for the subjects when a more or less frequent and constant change is going on, though at a comparatively slow rate. Again, a shallow piece of soil held constantly in artificial saturation will not long grow plants well; the initial cost, therefore, of the drainage suggested will be much best in the end. With the drainage inserted, a few thickly-cut grass turves should cover the whole, grass side down, and be tightly trodden in position. Should this be deemed insufficient, an inch or two of the original retentive soil will assist a slower percolation of the moisture through the turves to the drainage.

With such preparation an ideal spot will be formed for some of the most beautiful of shade and moisture-loving plants. The sloping sides of the bed will need no such preparation, as the drainage is secured to this portion by the deeper central section. All is now ready for the prepared soil. For the deeper part, peat, roughly broken, may be used for the bottom, taking care to rid it of Bracken roots where such exist. The remainder may be in the following proportion: Rough peat and half-decayed leaf-soil in about equal parts, a sixth part of good turfy loam, with a free addition of sharp sand and old mortar rubbish passed through a half-inch sieve. Such a soil is suggested in the face of the position given, and the exceptional opportunities thereby afforded for accommodating some of the best Lilies, otherwise many bog plants are as perfectly happy in wet loam as in any soil. This, however, is not the soil best calculated to grow a variety of things. The whole of the soil should be made tolerably firm and sufficient given to allow of settling and decay consequent upon saturation. In the shallower parts, or at least, a portion, the soil may be peat, loam and leaf-soil in equal parts, with an addition of sand. Provided no better means are at hand, such a bed may be amply supplied with moisture from a perforated pipe around the margin and in one or more directions across the centre of the bed.—E. J.

Propagating Acantholimon.—Coming across Mr. F. H. Neve's note in your issue of August 13, describing how he successfully increases *A. venustum*, I told the grower who has charge of the alpine plants here. He said nothing, but led me to a cool Orchid house, and there showed me a pan with about fifty cuttings of four different species of *Acantholimon* looking the picture of health. These cuttings, single rosettes, with half an inch of stem to each, from which the leaves were removed, were taken in June and dibbled into a layer of 1 inch of sharp river-sand, underneath which the pan contained a suitable compost for the young roots to penetrate into. The pan was placed close to the glass in the Orchid house (but in a position where the sun could reach only for a short time), covered over with a pane of glass, and given an occasional very slight sprinkling. When signs of growth appeared the glass covering was gradually removed. Out of the whole lot only five failures were indicated by vacant spaces. Another pan contained cuttings of *Armeria cæspitosa*, likewise a troublesome plant to strike. These also were doing well.—E. HEINRICH, *Munich*.

DELPHINIUM SULPHUREUM (ZALIL).

THE advent of the yellow-flowered Larkspur created an amount of surprise on a par perhaps with the first announcement of the scarlet kind, when the latter, in the shape of *D. nudicaule*, made its appearance many years ago. The point in common between the two species now mentioned, while differing widely in colour, in habit and stature, is due to the fact that a similar treatment is necessary, and both species are possessed of a somewhat similar tuberous kind of root. As may be gathered by a glance at the accompanying illustration, the species is somewhat tall and freely and distinctly branched. In this latter respect it is quite unique, as it does not form one strong central spike, with numerous smaller as well as much later lateral branches, as in the florists' kinds generally, but instead inclines from the first to develop what is obviously characteristic of the species, a decidedly forked habit of growth and flowering. All this is well shown in the picture, and equally so the apparent absence of foliage, which, to say the least, is an unfortunate drawback in a plant so unique and yet so amenable to culture in British gardens. Would the growers of the plant will doubtless be pleased to learn that the plant possesses the valuable characteristics of seeding freely as well as flowering freely. At the same time it should be pointed out that only in exceptional seasons and in the earliest flowered examples is there much hope even in the south of England of obtaining anything like a full crop of seeds. The latter are, however, to be purchased at a cheap rate from specialists in hardy seeds, which fact will make the plant worth growing freely and in groups in various positions in the garden. It will, however, be advisable to select rather sheltered positions, owing to the manner of growth and the widely-spreading habit of the inflorescence. The plant is a native of the hill districts of Afghanistan, where it is found in a wild state covering large areas.

One of the good features of the species, so far as concerns its culture in our gardens, is its freedom of flowering, an unusual characteristic of these tuberous kinds. To make sure of flowering plants, however, it is best to treat it as an annual, sowing the seeds in a warm manure frame quite early in each year. As soon as the seedlings are up and of sufficient size, give a liberal shift into 4-inch pots in good soil, made rather sandy and light. In the month of May the plants may be put out in groups in warm, sheltered positions in the garden, half-a-dozen or so plants making a fine feature when in flower. A few of the more vigorous seedlings may flower the first season, but the best results are secured when the flowering is delayed till the next year. The flowers are generally so abundant that the plants are more or less exhausted. At the same time, if the winter prove a mild one, a few of the roots may survive, if protected by leaves or a handful of cocoa-nut fibre. During the past summer the plant has been shown in capital condition before the Royal Horticultural Society. E. J.

Mr. M. Kingsley, Bourne Orchard, Hertford, sends us the following note *re* this *Delphinium* :—

I send you a photograph of a group of *Delphinium sulphureum* in the rock garden here. The plants were grown from seed sown in January, 1897, and are now flowering for the first time. The largest is over 6 feet high. They have received very little care beyond occasional watering and a dressing of manure, but their success has given a special charm to that part of the garden.

LILIUM OCHROLEUCUM.

(L. SULPHUREUM.)

THE opening up of some parts of Burmah a few years ago was the means of introducing a few distinct Lilies into British gardens, the first to flower being the striking *L. nepalense*, which was so different from previous descriptions of it, as well as from any other Lily in cultivation, that it attracted a very great share of attention when first exhibited. After that came the magnificent

certainly difficult to understand that a botanist of Wallieh's experience should ever have given the specific name of *ochroleucum* to the Nepal Lily, while it might be appropriately bestowed upon that previously known as *L. Walliehanum superbum*. However, further controversy was silenced by Mr. Baker reconsidering his previous decision, and assigning the Lily specific rank under the name of *L. sulphureum*, which must therefore now be regarded as the correct name of this stately Lily. Its prominent characteristics are well shown in the

Part of a group of *Delphinium sulphureum* (Zalil). From a photograph sent by Mr. Kingsley, Bourne Orchard, Hertford.

Lily figured on page 259 as *L. ochroleucum*, also totally distinct from anything else. The nomenclature of this aroused a good deal of controversy, as when first flowered by Messrs. Low it was named by Mr. Baker *Lilium Walliehanum superbum*, a very inappropriate name for a Lily that differed in nearly every particular from *L. Walliehanum*. I pointed this out at the time and suggested it might be the *L. ochroleucum* of Wallieh, which has been referred to *L. nepalense*, but it is cer-

tainly difficult to understand that a botanist of Wallieh's experience should ever have given the specific name of *ochroleucum* to the Nepal Lily, while it might be appropriately bestowed upon that previously known as *L. Walliehanum superbum*. However, further controversy was silenced by Mr. Baker reconsidering his previous decision, and assigning the Lily specific rank under the name of *L. sulphureum*, which must therefore now be regarded as the correct name of this stately Lily. Its prominent characteristics are well shown in the illustration on page 259, where several of its most distinctive features may be noted. Particularly prominent is the great number of its rather narrow leaves, the presence of bulbils in the axils thereof, the large massive flowers, and the bold and striking appearance of the entire specimen. The colour of the flowers is a kind of ochre-yellow in the interior of the tube, the recurved portion being of a milk-white hue. The three outer segments are usually tinged with purple on the exterior, but this feature varies a good deal according to the amount of exposure they have received. The leaves, too, in a young state are tinged with reddish brown. The bulbs of this species are large, compactly built, and of a deep brownish colour, a tint but little represented among its immediate allies. The before-mentioned bulbils in the axils of the leaves are particularly interesting, as this species is the only one belonging to the Eulirion or tube-flowered group of Lilies in which this feature occurs. In this the bulbils are a good deal larger than those of the Tiger Lily, which is the best known example in our gardens of this peculiarity. I was extremely pleased to hear that this grand Lily had withstood the last two winters in the open ground in Dorset, and hope it will continue to improve and become permanently established. It certainly succeeds much better under cultivation than any other species from the same region.

H. P.

Phygelius capensis.—I am surprised to

see some doubt cast on the hardness of this plant. Certainly it does best in places where the winters are mild, that is if it gets an open position with plenty of sunlight, as it then commences to flower earlier and keeps on throughout the autumn, besides which the colour is brighter in such places. As to its hardness, I may say that it has been grown here in the open border without any protection for the past eleven years, during which period it has experienced a tem-

perature below zero many times, and early in 1895 no less than 7° below for several successive nights, which is a test sufficient for most places, and it has always grown away strongly again and flowered more or less freely each autumn. It is only fair to add that the soil is sandy and light. One group stands within a very few inches of water level, which is not the most desirable position for the plant. It was simply planted there to test its hardiness.—J. C. T., *Livermere Park, Bury St. Edmunds.*

Plumbago Larpentæ.—I have never tried this plant on a sunny wall as suggested by Mr. Arnott (p. 260), but can quite imagine that it could easily be made a success in such a position, and I think the suggestion a valuable one. In a very dry border, the soil of which is shallow, of a peaty nature and filled with the roots of shrubs, it is one of the happiest of plants and shows no signs of distress even in this dry season. Just now it is well in flower, and many of the leaves have assumed a brilliant orange-red colour. These will remain after the flowering is over and continue to make the plant interesting. Mr. Arnott gives a very interesting account of the difficulties found in cultivating it during the early period after its introduction, but I think that its scarcity even now goes to prove that its requirements are not yet thoroughly understood. When planted where the soil remains moist for many months of the year, it has a way of dying out, and is consequently looked upon as a difficult plant to keep, but by changing the position and planting in a dry and rather poor soil it gives no trouble. The spot selected need not be a sunny one, as it does well with me in comparative shade, but the other conditions for its welfare are imperative if the plant is to become established and live on for years without much care being expended on it.—*CORNUBIAN.*

PLANTAIN LILIES FAILING TO FLOWER.

I HAVE been growing Funkia subcordata grandiflora under a south wall, but it does not blossom freely. The flowers do not come out well. Would it do well under a wall in a half shady place?—*W. W.*

* * * A position "under a south wall" is too hot to suit the requirements of any of the bolder kinds of Plantain Lilies unless the soil is particularly good and deep and considerable attention paid to watering in summer. A partially shaded position would suit the plant well provided the shade is given from a distance and the soil not greatly impoverished by tree-roots. All these Plantain Lilies are quite easily grown, and you would do well to select a rather more open spot if possible with distant shade in the hottest part of the day. Your failure has more to do with soil and heat than aught else, and suggests the desirability of a rather deep bed at least 2 feet of good loamy soil rather holding than otherwise, and abundantly enriched by rotten manure. It may be well also to divide the plants and replant them in one large group, allowing a fair distance for future development rather than replanting the example bodily. The division may, however, prevent the flowering of the plant for a season. In any case the group would show a decided improvement a year later by the increased vigour of the crowns, which in turn should flower the season ensuing. Bold and vigorous by nature, great rooters, and gross feeders also, these plants should always be liberally dealt with if free-flowering is required, or even where the best results are expected from them even as fine-foliaged plants. In the case of established clumps, either a liberal mulching or frequent soakings of liquid manure during winter will prove beneficial. In dividing large clumps pieces of 6 inches or 7 inches diameter would be small enough, grouping these a foot asunder or rather more, and so forming one large irregular group. When replanting in the open do not bury the crowns too deeply, 2 inches or 3 inches of soil above them being sufficient, making all quite firm. These well planted with mulchings each year would remain several seasons in excellent con-

dition, and for a space of three or four years continue to improve. This is especially the case where there is no lack of summer moisture. This year, however, not a few of such vigorous rooting perennials are suffering from the want of rain.—*ED.*

FLOWER GARDEN NOTES.

THE present season seems likely to establish a record for the duration of summer-flowering tender plants, as up to the present time (October 20) nothing is injured, if we except the browning of a few Dahlia tips, and there is still a very fair amount of bloom. The Dahlias were only partially hurt, and it has not interfered with the flowering to any appreciable extent; the back blooms have pushed up quickly, and I am cutting very fair supplies two and three times a week. Tropæolums, both single and double, and Heliotrope plants, that rank among the most tender, are uninjured, whilst hardier things, as Ageratums, Marguerites, Fuchsias, Begonias, both tuberous and fibrous, are not only unhurt, but are still quite a mass of flower. We had 5°, 6°, and 7° of frost on successive nights in September, but everything was at the time wonderfully dry, and so escaped. It is, however, quite certain that, although one may regret the necessity of removing plants still well in flower, the operation must be performed if a spring display is required, as those things prepared for this are more than ready; also where bulbs are to be planted it is quite time they were in, and if the season is allowed to get on too far, a spell of bad weather will cause further delay. Elaborate autumn planting is only available in public parks or in private places where labour is plentiful, and I hardly think the result is so satisfactory as when beds are filled in a simple manner. If they are fairly close together, it will be well to fill each with the one shade rather than attempting edgings or mixtures, and a judicious selection will give both great variety and a fine display. Wallflowers may be represented by good strains—dark red and deep yellow, sulphur-yellow, Harbinger, and Ruby Gem. Polyanthus, if sown in separate colours, will give white, primrose, yellow, terra-cotta, purple, and crimson, both light and deep, whilst Silene will supply the pink and Myosotis the blue. If it is thought advisable to relieve the flat surface inseparably to all the things above mentioned, a few small conifers may be dotted among them, regulating the number of the small trees by the size of the beds, so that just sufficient are employed to break the carpet, and not so many as to suggest crowding. Retinosporas in various shades of green, gold, and silver are best for the purpose. Where a stock of them once acquired is held over for several years they will require a little special attention through the summer months, especially in seasons like the present, to see that growth keeps well on the move and there is no sign of getting brown and subsequently bare patches. When lifted at the end of spring, both head and root should be trimmed over to regulate straggling growth; they should be planted on a border with a northerly aspect, mulched, and well supplied with water if the weather renders this necessary. If more bright colour is required than is likely to be furnished by the things mentioned above, Tulips, Hyacinths, and Daffodils may be planted in more or less numbers, as may be deemed advisable. The practice of mixed planting seems to be increasing in favour quite as much in spring as in summer bedding, and Polyanthus beds of all shades, also Silene and Forget-me-not, are found thickly studded with Tulips and Daffodils. There is no mistake about the brilliant display, but it looks artificial, and this should be avoided as much as possible in the spring garden (at least that is my idea); if the mixtures are required, the gardener has no alternative but to cater in this direction.

PERMANENT EDGINGS that are getting thin and ragged may be taken in hand at the present time whilst the weather is suitable, and if there is any

doubt as to their ability in their present form to furnish the ground thoroughly another season, it will be advisable to lift entirely and replant. Long herbaceous borders that I am gradually filling up with clumps of different things in various heights to within a foot of the walks have been fronted with stretches of Chamomile, dwarf Sedums (both green and variegated), Veronica incana, Tufted Pansy Violetta, Saxifraga umbrosa, Phlox setacea, the newer Aubrietias, with smaller bits of Gentiana acaulis and Heuchera sanguinea. With beds on grass I would not suggest any regular lines of dwarf subjects for the outer edge, but, given long borders on either side a gravel path where there is a considerable amount of traffic, it is the better plan, as taller things are apt to get in the way, and the outer stretches can always be so planted as to harmonise with the things immediately behind them. All propagation by division of any good species and varieties on the hardy plant border may now be pushed forward, as, with the exception of a few Helianthus and Starworts, the flowering season is nearly at an end. *E. BURRELL.*

Claremont.

Morina longifolia.—When looking through Mr. G. F. Wilson's Wisley garden in July last I saw some clumps of this in full bloom, and in the middle of September they were still effective. Any hardy flowers that will remain attractive for so long a period in a time of great heat and drought are of much value. This Morina is handsome and distinct, throwing up flower-stems each about 2½ feet high, the white and rose-coloured flowers being shown off to great advantage by the bright green foliage.—*J. C. B.*

Carnation Celia.—Of all border Carnations, I know of none that in hardiness of constitution and free, stout habit of growth surpasses Celia. I had some plants from Mr. Allan, of Gunton, with whom this variety is a special favourite. Well-rooted layers form quite large plants by November when transplanted in August, and flower freely the following summer. The flowers are of extra large size, the colour being a beautiful bright shade of pink. The blooms are borne on extra long stems and are not soon damaged by wet. A good-sized bed filled with Celia has a charming effect when the plants are in full bloom. Its sweet scent adds greatly to its value. It continues to yield a succession of bloom until late in the autumn.—*C.*

Aster alpinus.—In the account given last week of the alpine Starworts by "E. J." I am surprised to read that they require perhaps the least care of any plant in the open rock garden. I can only say that, though I have succeeded in growing and flowering admittedly difficult alpine subjects, I have not as yet been successful with these charming plants. Judging from the freedom with which Aster alpinus grows in the Dolomites, I surmise that it is a lime lover, and the account given by "E. J." prompts me to try a richer soil than is usually given to alpine. At any rate the alpine Asters are so beautiful that I must not acknowledge failure, but go on trying until I do succeed, as I have done at last in the case of Gentiana verna. It will probably prove that it is easier to grow this plant from home-reared seed than by importing plants from the Alps, the plan I have hitherto adopted.—*HERBERT MILLINGTON, Bromsborne School.*

Wintering Brompton Stocks.—As a rule cottagers grow the finest Giant or Brompton Stocks, the reason for this being that the seed is sown pretty early, fine plants secured, and if they survive the winter, grand spikes of bloom are produced the following season; whereas many gardeners, knowing the liability there is to damage or complete destruction from frost, sow later, pot off the plants say in August, and after giving frame or pit protection through the winter, finally plant in the open ground as soon as danger from frost is past. If large enough pots are given to this strong, free-rooting variety and spring planting carefully performed, good soil being

given, good spikes of bloom will be forthcoming, but not equal to those from strong autumn-planted batches, especially after winters like last. It is a good plan to plant some out in their permanent quarters and pot up others; by these means a blank is avoided. The finest Bromptons I ever saw were grown by a cottager in warm loamy soil in the sheltered angles of his cottage. He had saved the seed for years and the strain was grand.—J. CRAWFORD.

FUNGI'S ON VIOLETS.

I WILL be obliged if you could tell me of any cure for the fungus on the enclosed Violet leaves. The Violet plants suffered from the same attack last year in the frames.—C. M.

* * * Your Violets appear to be attacked by a fungus unfortunately too well known amongst Violet growers. Your plants are not very vigorous, and weakly plants more readily fall victims to disease. When once it sets in there seems really no cure, although its progress may be checked by careful airing and watering. There are market gardeners around Norwich who have had to abandon Violet culture altogether on account of the fungus, and a very successful private grower in East Anglia had his plants so badly attacked by the disease, that he was obliged to destroy them and procure a fresh stock from a distance. Since then his plants have, I think, been free from its ravages. I should advise the same course being followed in your case, the new plants or runners being planted in a fresh place, or if in a border occupied by the affected plants either last year or this, the old soil to be entirely removed to a depth of a foot or, better still, 15 inches, this being either burnt, so as to render it harmless, or buried, and replaced with a fairly retentive loamy soil, to which add freely either leaf-mould or spent Mushroom manure and road grit, mixing them thoroughly. The soil in the frame must also be removed and the wood-work painted, as to put fresh plants in without this renewal would be to court failure. In order to keep the fungus as much in check as possible and give the plants a chance of partly growing out of it, be careful in airing the frames throughout the winter. While checks from cutting winds must be guarded against, as much fresh air as possible must be admitted, and even on wet days tilt up the lights sideways so as to admit of a free current passing over the foliage. Water thoroughly when necessary, choosing a sunny, breezy day for the operation, but avoid constant dribbles, which keep the atmosphere overcharged with moisture. On foggy days, however, keep the lights quite closed rather than admit the obnoxious vapour. I have known plants of weakly growth to which no ball of soil could be secured when lifting have to be kept close for some time and syringed after being put into the frame. This treatment predisposes the plants to disease. *Bona fide* runners, rooted early by working fine soil amongst the plants in March or early in April, are far better than divisions of old plants planted out with wigs of roots. These may look more promising for a time, but they seldom do satisfactorily and generally lift badly.—J. C.

NOTES AND QUESTIONS.—FLOWER.

African Marigolds.—These have been for several weeks quite a show, and will continue till frost destroys them. When sown early, planted in good soil, and attended to with water in dry weather, they attain to 3 feet high and each give from six to a dozen large heads. When used as I now have them in masses in mixed hardy plant borders they are most useful.—DORSET.

Anemone japonica.—Opinions differ as to whether there are two forms of this. Some growers contend the difference arises from soil. I am convinced there are two forms of it. The one has much deeper-coloured flowers and more petals. The paler form is not worth growing compared to it. I was under the impression the soil caused the difference

till some eight years ago I received a plant of the better-coloured form.—DORSET.

Crocus speciosus.—This beautiful species—to my thinking the most lovely Crocus grown—is now flowering in my garden, and so fine is it that I may assume that the drought has not affected it injuriously in any way. When at Gumpersbury House a few days ago I noticed that Mr. Hudson had planted the small circular beds round the standard Roses in the flower garden with *C. speciosus*. There is no vernal Crocus I am acquainted with that can rival this fine autumn-flowering form for such a charming tint of blue, and yet how seldom one sees it in gardens, or even hears of it. It requires to be planted deeply in rich soil and let alone, taking care not to disturb it. It will do in sunless as well as sunny spots, but appears to come finest under a wall with a west aspect.—R. D.

TREES AND SHRUBS.

THE HAZELS.

(CORYLUS.)

JUST now, whilst it is autumn, the Hazels are noticeable chiefly for the rich yellow of the decaying leaves, and whilst there are other trees and shrubs whose autumn tints are brighter, there are few that retain their beauty so long.

Hazel catkins.

I can call to mind a large patch of planted Hazels that clothes the lower slopes of one side of a steep north-country valley and fringes the stream at its base, and when seen in "the serene and yellow leaf" from the summit of the opposite side it forms in its soft and quiet beauty one of the most characteristic and, therefore, satisfying English autumnal scenes I know.

Like the Alders, the Poplars, the Birches, and the Willows, the Hazels belong to the great catkin-bearing family, and of the shrubby catkin-bearers native of this country, the common Hazel (*Corylus Avellana*) is the first to flower. The male or pollen-bearing catkins appear in autumn; they are, indeed, already an inch or so long, little, dark, cylindrical bodies clustering in the axils of the leaves all over the plants, whilst the nuts of the current year are still hanging. Sometimes the male catkins will be in full flower before November comes in, but

that is premature. The proper time for them, and the time when most of them appear, is about the middle of February. Then, or it may be a little later, they grow to be some 2 inches or 2½ inches long, the anthers burst, and they become a pretty soft yellow. A Hazel bush, covered with its slender yellow catkins swaying gently in the breeze, is one of the most delightful pictures of early spring. The female flowers burst later and are less conspicuous than the male; they are produced in bud-like catkins which, when they open, disclose the crimson styles. The beauties of the Hazel flowers are only of a modest kind, depending more on their peculiar grace than on their colour. It is the season at which they come that makes them so welcome and cheering.

There is a certain individuality about the habit of the Hazel that makes it one of the most picturesque of our native shrubs. Its largest stems (often springing out of a thicket of slender wand) are mostly crooked and do not branch much till near the top, then ramify into an irregular, more or less bushy crown of leaves and shoots. It makes an admirable undergrowth. It has also been used for the making of arbours, pleached alleys, and such like. The covered walks that so frequently may be seen in the grounds of the old châteaux of France were often made of the Hazel. For such purposes the great pliancy of its branches, as well as its hardiness and longevity, admirably adapt it. It may by artificial means be made to assume the form of a tree. Loudon mentions trees of Hazel in Eastwell Park, which, having been drawn up by neighbouring Thorns, Crabs, &c., were upwards of 30 feet high, and had trunks 1 foot through. As a rule, however, it sends up a number of branches, none of which ever get very big. In consequence of its small size the wood is not of much value in manufactures, but it is sometimes used in the finer cabinet work. Large roots, too, furnish a very pretty veneering wood. The varieties of

CORYLUS AVELLANA are numerous, many of them depending on the size and shape of the Nut, the thickness of the shell, &c. Others, however, have no distinctive qualities as fruiting shrubs, but differ in habit, shape, and colour of leaf, &c. Of these the following are the more noteworthy:—

C. A. VAR. AUREA, with yellowish leaves.

C. A. VAR. CONTORTA.—This is remarkable for its curiously twisted, distorted branches. It was discovered in a hedgerow near Gloucester about thirty-five years ago, but it is still uncommon.

C. A. VAR. HETEROPHYLLA (syns., *C. laciniata*, *C. arcticafolia*).—A very pretty variety whose leaves are deeply cut into numerous pointed lobes, these lobes being again sharply and irregularly toothed. This variety must not be confounded with *C. heterophylla*, a distinct species from Japan.

C. A. VAR. PENDULA.—This is a weeping form of the common Hazel, and trained up as a high standard makes a very graceful, small tree.

C. AMERICANA.—The common American Hazel differs but little from *C. Avellana* in general appearance. It has leaves and fruits of about the same size and character, and the shrub itself is of much the same type, but not so tall or sturdy in habit. It is a native of the eastern side of North America, being found in thickets and low, shady woods. It was introduced to this country in 1798 by the then Marchioness of Bute.

C. COLUBINA (the Constantinople Nut).—This is noteworthy among the Hazels on account of its size, being the only one in this country that naturally forms itself into a tree. I have seen specimens upwards of 40 feet high, and Loudon states its height to be 50 feet to 60 feet. It is a native of the Levant, whence it was introduced to Britain in the seventeenth century, some time prior to 1665. It seems to have reached Central and Western Europe almost a century

earlier, having been sent to the botanist Clusius from Constantinople about 1580, possibly at the same time as the common Horse Chestnut, which first became known through him about that date. Its leaves are narrower than those of our native species and have more deeply-cut margins. The nuts are small, rounded, and covered with a large calyx, which is cut into numerous long, narrow segments and fringed. It has occasionally produced good fruit in this country and has been raised from English seed, but is of no value as a nut-bearer. At the same time it makes a very interesting and handsome tree. There is a good specimen not far from the main entrance to Kew Gardens about 35 feet high, the trunk well formed and straight, measuring 4 feet 6 inches in girth at 2 feet from the ground.

C. MAXIMA (syn., *C. tubulosa*) is the species that produces the Ceb Nuts and Barcelona Nuts, which are distinguished from the Filberts by their thicker shells and more rounded shape. The plant itself is a native of Southern Europe and is of bigger growth than our native species. It has figured under various names, and by some authorities (including Loudon) has been considered to be merely a variety of *C. Avellana*. The present name was given to it by Philip Miller. It has many varieties, but the only one that concerns us as an ornamental shrub is the well-known

C. M. VAR. ATROPURPUREA (the purple-leaved Hazel). To these who are fond of shrubs with coloured leaves this may be recommended as one of the best of the purple ones. Its leaves are of a brighter shade than many of the same class.

C. ROSTRATA, the Beaked Hazel, is a native of Eastern North America. It is a bushy shrub, rarely more than 5 feet or 6 feet high, and chiefly remarkable for the curious hairy calyx, which is prolonged $1\frac{1}{2}$ inches beyond the apex of the Nut and forms a curved beak. It has fruited at Kew during the last few years. It was introduced to Britain by the Duke of Argyll in 1745. There are two other species in cultivation at Kew, viz.,

C. HETEROPHYLLA AND *C. MANDSCHURICA*. Both are natives of Japan and the neighbouring countries and have been raised from nuts sent by Dr. Bretschneider from Peking. They are shrubs of apparently the same character as *C. Avellana*, and it is not likely they will prove to be of any greater value than it is. But at present there is nothing to be said on that point.

The Hazels are very accommodating plants and will grow in any loamy soil, preferring that, however, of moderate richness and of a calcareous nature. This matter of soil is more important where they are cultivated exclusively for the nuts, but the Hazel may often be made to serve its useful purpose as a fruiting shrub and play its part in the landscape as well. Every garden can grow the purely ornamental varieties mentioned above. Propagation of the true species should always, if possible, be effected by means of seed, or, failing that, layers. In planting *C. Columna* especially, care should be taken to see that it is on its own roots. It is sometimes grafted on *C. Avellana*, which, being a shrub, is quite unsuited as a stock for so large a tree as this. The purple-leaved Hazel should be increased by layers or by division, methods that are also suitable for the other varieties. W. J. B.

Cotoneaster frigida.—This Himalayan species of *Cotoneaster* is a decidedly ornamental plant in the spring when laden with its clusters of white blossoms, but it is far more attractive just now when the flowers have been succeeded by fruits, which are about the size of small Peas and bright red when ripe. While many members of the genus are remarkable for their ornamental fruits, this is one of the best of the larger growing kinds. The berries remain fresh and bright for a longer period than they do in the case of many of our fruiting shrubs.—T.

Planting Hollies by roadsides.—I have often thought it a pity for young Holly trees to

be planted close to public roads in the vicinity of large towns, as they get damaged as soon as they arrive at a fruiting stage. This is especially the case for a distance of thirty miles round London. I know of some trees growing in the hedge of a churchyard facing the high road, and they are invariably damaged as Christmas approaches. One clergyman used to have the berries picked off when the trees were small, which, of course, spoiled their appearance. I have heard of young trees full of berries being cut off at the base and carried away entire. The same remarks apply, though perhaps in a less degree, to Laburnums, Lilacs, and Flowering Thorns.—C.

Ligustrum Walkeri.—"B." in a recent issue is deserving of all thanks for his outspoken remarks concerning the above weed. Like "B.," I was astonished at so unattractive a plant receiving recognition of any kind, and must confess my surprise when I found that the first-class certificate was really no error of the attendant in placing a wrong card, but that the floral committee, or at least a majority of that body, had really made the award in question. So far as my judgment permitted, I could not see one redeeming feature in the plant, and it is doubtful whether those who voted the first-class certificate in question could really point out any merit in the plant at all. Something should be done to save, as "B." puts it, the honour of the society, and to make its awards of some real value in the eyes of the world of horticulture. At times the table devoted to plants for the committee to sit in judgment upon is simply loaded, and frequently things are brought to the meetings with the full knowledge that they are neither new nor rare, or even possessing any special merit, but simply because this or that has never been certificated at all. Quite recently an award of merit was given to *Hibiscus totus albus*, a plant that over and over again has been shown in full flower in large plants in baskets, yet finally meriting (?) recognition when half a dozen sprays were shown in a jar, the entire exhibit being about 8 inches high. Such doings cause one to wonder and to ask, What next?—A FELLOW OF THE R.H.S.

ROSE GARDEN.

ROSE Mlle. EUGENIE VERDIER (H.P.). THIS Rose, one of the loveliest of the Victor Verdier race, has been exceptionally fine this autumn. Its bright flesh-coloured flowers and exquisite buds are attractive at any time, and the silvery white shade upon the reverse side of the petals appears to me to constitute a sufficient distinction between this Rose and Marie Finger, a variety with which it is bracketed as being too much alike by the National Rose Society. It may be that both varieties are not required in an exhibition box, but no one will regret adding the two kinds to his collection for garden decoration. Its growth is robust, not vigorous, but it will in a good Rose soil make a very fine bush, and is better adapted to this mode of culture than as a standard. It is a fine variety for pot culture. The climbing form is an excellent free-growing sort for pillars or fences. It is not a rampant climber like Climbing Jules Margottin, and its growth is rather stiff and formal, but yet it is very valuable for its colour. As might be expected from its parentage, Mlle. Eugénie Verdier is quite scentless, but, although we deplore this fact, it does not warrant us in discarding such a beautiful variety—at least not until it is superseded by a fragrant one.

Great confusion is caused in these "Verdier" Roses owing to the similarity of names, and to obtain what one desires it is very necessary to stipulate class and colour. For instance, there is the variety under notice. This was raised by Guillot in 1869. As the prefix Mademoiselle

is most often dropped, it makes it uncertain whether this variety is intended or one raised by the same individual six years previous, the colour of this latter being a deep red. Then, again, there are Mme. Eugénie Verdier, a rose-coloured Hybrid Perpetual, and Mme. Eugénie Verdier, a golden yellow, semi-climbing Tea Rose. To increase the confusion there are a Souvenir de Mme. Eugénie Verdier, a very large, flat, bright rose, and also a Souvenir de Mme. Eugénie Verdier, a lovely, nearly white kind belonging to the Hybrid Tea section. Then, of course, there are the old rose-coloured Victor Verdier, the crimson Mme. Victor Verdier, and another crimson Souvenir de Victor Verdier. It seems a great pity our French neighbours, through their excellent Rose Society, cannot do something to mend matters by asking raisers to give simple names of about two syllables to their Roses, and if they require examples, there is plenty among recent English and American novelties. PHILLOMEL.

Red rust on Roses.—Would "S.," who in your issue of the 17th ult. so kindly gave the readers of THE GARDEN his experience and a recipe against mildew on Rose trees, express an opinion as to a safe mode to extirpate red rust from Rose trees? This pest appeared among my Roses some two years ago, and all attempts to stop its ravages have thus far proved fruitless. The soil is dry during six months in the year, and has to be artificially watered very often. The atmosphere is parched during such months through a clear and cloudless sky, thus exposing the plants to a fierce sun for about fifteen hours a day.—MALTA.

Autumnal Roses.—What a wealth of bloom is often seen in autumn on well-established trees of Gloire de Dijon. Not many yards from where I write is a tree occupying the front wall of a cottage, and in August it was laden with blooms of good size and colour. Gloire de Dijon has justly been termed the poor man's Rose, thriving as it does in any kind of soil, and succeeding either as a standard, dwarf bush, or trained to a wall. Another good autumn Rose seldom seen now-a-days, but which deserves a place in every garden, is Souvenir de la Malmaison. It is not of exhibition form, perhaps, but of delightful colour and fragrance, being of a lovely pale flesh shade, strong shoots on large bushes furnishing a wealth of bloom over a long period in autumn. This old Rose, though somewhat stiff, has a good effect arranged by itself in large vases. It is a capital grower, and where room can be spared in the Rose garden it deserves a bed to itself.—NORWICH.

Tea Roses in the flower garden.—At the end of the summer I called at Honeycott House, near Minehead, and when walking round the flower garden was struck with the number of hardy plants used. Some long beds were devoted to Tea Roses, with Mignonette growing amongst them. The Roses were full of flowers and growing very freely. Evidently the soil, a sandy loam, suited them. A few of the best in bloom at the time of my visit were Anna Olivier, Comtesse Riza du Parc, Dr. Grill, Grace Darling, Homère, Luciole, Isabella Sprunt, Mme. Charles, Mme. Lambert, Papa Gontier, Safrane, Perle des Jardins, and Catherine Mermet. The situation is sheltered from the north and east by big trees, and not more than a mile from the sea. Where this lovely class of Rose will thrive in this way, nothing is more useful for the flower garden.—J. CROOK.

Autumnal Rose shows.—The recent splendid displays of Roses at the Brill Hall meetings of the Royal Horticultural Society show what one might expect if Rose societies organised autumnal exhibitions. It is true the drought has been responsible for somewhat thin blossoms, but there has been a glorious profusion. I think Rose societies should encourage the general public to take up Rose growing for its decorative possi-

bilities rather than from an exhibitor's standpoint. They do not wish to become exhibitors; they want to know what to grow and how to grow it, and the fat, dressed-up blossoms at the summer shows only tend to dishearten the non-rosarian, for he knows full well that he can never hope to produce anything like them. But show him a bunch (not artificially dressed) cut with all the buds of such kinds as Caroline Testout, Viscountess Folkestone, Mme. Hoste, G. Nabonnand, Camoons, Marie d'Orleans, Mme. Abel Chatenay and the like, and tell him such kinds are practically perpetual and of easy culture, then may new recruits be added to the ranks of Rose growers.—PHILOMEL.

Roses White Pet and Red Pet.—These are both excellent garden Roses. The former is by far the showier variety, its immense corymbs of blossom being probably unsurpassed by those of any other dwarf Rose. The flower is almost an exact counterpart of that of the grand old climber *Félicité-Perpétue*, and everyone knows what a delightful little rosette each flower of this Rose makes. White Pet is almost as attractive in autumn as it is during the summer; whereas *Félicité-Perpétue* is summer-flowering only. The delightful tiny crimson buds, no larger than peas, give an additional charm, and are brought into much prominence when seen peering from among the white blossoms. There is no better white Rose for small pots, and market growers employ it largely for this purpose. The Red Pet has not much in common with the above, as one might suppose from its name. Its colour is rosy crimson, the inner petals having paler edges, but the older blossoms change to quite a maroon colour. The flowers are not borne in such large trusses as in White Pet and they are not so perfectly formed.—P.

Rose Perle des Jardins.—This variety is certainly the best of all the dwarf-growing yellow Teas, the blooms, although not large, being very double. It has also lovely formed buds which find a ready sale. For the private grower this Rose would be found most useful where a constant supply of blossom is required. Even if a small house were devoted exclusively to it it would be found to well repay for the sacrifice, especially if the plants were planted out. Such plants will last for many years, and will eventually become in a good Rose soil immense bushes a yard or more through. In some localities this Rose succeeds well outdoors, but it is not a general success. It appears to require a steady artificial heat. *Perle de Lynn* closely resembles this Rose, but its blooms usually come quartered. It really is not necessary to have both varieties, and certainly *Perle des Jardins* is the better. It has given a delightful sport in *Sunset*. The colour is rich apricot, something in the way of *Mme. Faloot*. The climbing form of *Perle des Jardins* is a most luxuriant grower. It is unfortunately rather tender and much addicted to mildew outdoors, but, given a sheltered spot and a good root run, it should prove a valuable kind where *Maréchal Niel* fails. Under glass it would make a grand climber for lofty conservatories or green-houses.

Yellow climbing Roses upon standard Briers.—Probably no varieties of Roses give such satisfaction upon standard Briers as do the climbing Tea-scented and Noisette tribes. They produce graceful arch-like shoots in such rich profusion that all formality is absent. This is not the only advantage of thus growing these Roses. One cannot well have too many yellow Roses. The demand for them exhibits no sign of abating, and if this be so, where can we look for them save among the so-called climbing kinds? Should wall space be limited, it is an excellent plan to have a goodly number of such standards. Give them ample space for development and feed them liberally with liquid manure: they will then make most beautiful objects either for beds skirting the lawn or as isolated specimens. In pruning them it must be borne in mind that the long one-year-old growths, if well ripened, give the best and most blossom, therefore they must

be left a good length. If the plants are lifted every four or five years their somewhat over-luxuriant growth will be partially checked and the quality of blossom greatly increased. Everyone knows what a fine standard *Gloire de Dijon* makes. In many respects this Rose is unsurpassed for the purpose, although for refinement of blossom it is eclipsed by *Belle Lyonnaise* and *Bonquet d'Or*, the latter one of the best and most reliable yellow Roses grown. *Le Soleil* is also good. It is wonderfully like the white *Maréchal Niel*, which is not white, but the palest creamy yellow. In the autumn the edges of the petals of *Le Soleil* have a beautiful tinge of carmine. *Mme. Berard* is another excellent kind, and although it can hardly be called yellow, it is generally classed among Roses of this colour. Its lovely rosy apricot buds are invaluable for cutting. Then there is *Celine Forestier*. What a delicious shade of primrose-yellow we have here! It flowers best upon lateral growths; these should therefore be preserved when pruning. Then again there is *Maréchal Niel*. Given a sheltered nook this will make a glorious weeping tree. It is advisable not to have the stem too tall: about 3 feet high is best. If very severe weather threatens, the heads may have some slight protection.—P.

PRUNING TEA ROSES.

I WOULD be obliged if a Rose grower would tell me if it is best to prune the Tea Roses severely or not. My own experience would dictate that most of the Tea Roses require very little pruning, but my gardener insists on pruning them severely every year, and though they flower pretty freely, the plants remain very small and stunted. Some of the more vigorous growers, such as *Mme. Nabonnand*, *Gloire Lyonnaise*, and *Mme. Lambard*, seem to throw up stalwart growth, but most of the plants seem to succumb to the severe treatment and to remain extremely small.—D.

* * * In our country the question of pruning in all hard winters is settled by the Tea Roses being cut down by frost. If on their own roots or grafted very low, and the junction of the graft and stock buried, they escape and come up again; so in this way the pruning is simplified. In mild winters when not affected by frost, they must be cut back so as to remove all the small shoots that in many kinds break into too many buds, but this need not be done severely. The cause of some of the kinds being very small is their being worked or grafted on the *Manetti* or some other unsuitable stock. As we go now, every Rose is grafted in the same way, so that if the Rose does not like the stock, it must make the best of it. If the Roses are worked very low, sometimes they free themselves. We are continually being told by the trade that Tea Roses will not grow on their own roots, which anyone who cares about Roses can disprove for himself by taking some of the good half-ripened wood of the best kinds in September or October. This will often strike in the open air with success. A greater number need bell-glasses or hand-lights. Such kinds as *Princesse de Sagan*, *Mme. Hoste*, *Georges Nabonnand*, *Anna Olivier*, and *Gloire Lyonnaise* are among the best kinds ever brought to this country, and might be taken for trial in this way.—ED.

NOTES AND QUESTIONS.—ROSES.

Rose Marguerite Bondet (H.P.). What a pity this free-flowering Rose is not a better grower. Its exquisite form is its strong point, and for this reason it is a favourite with exhibitors. I have seen it has more than once secured the silver medal as the best H.P. in the show. The colour is delicate silvery white, shading to pale lilac in the centre. This Rose is said to be a cross between *Viet* or *Verdier* and *Virginal*, and it certainly bears a striking resemblance to the *Ermer* in bud.

Rose Louise Darzens (Hyb. Noisette).—This excellent little Rose, introduced by Lacharme nearly forty years ago, is very distinct even among the dozens of white varieties already in commerce. Although

for all practical purposes the flowers may be termed white, yet there is a charming tinge of flesh-pink pervading their petals. The habit of growth is rather spreading, so that if plants are set out 2 feet apart they quickly meet each other. The flowers, which are double and regularly formed, are produced in fair-sized clusters, and like the whole of these Hybrid Noisettes, they are very freely produced during the autumn months.

Rose Ferdinand Batel.—Further acquaintance with this beautiful Hybrid Tea strengthens the favourable opinion formed of it when under glass. Its delightful colour pleases everyone who has seen it. There is much of the rich nankeen-yellow in this Rose that is so conspicuous in that fine climber *Mme. Chauvy*, and this colour is intensified in autumn in the flowers borne upon the secondary shoots. The edges of the petals, moreover, are of a pale chambré-yellow, which is an additional attraction, as it lightens up the flower immensely. In the early summer the blossoms vary in colour from rosy flesh with yellow base to rich apricot-yellow.—P.

STOVE AND GREENHOUSE.

RIVINA HUMILIS.

I AGREE with all that "T." says as to the value of this fine old berried plant, which should never be trained out of its lovely growing natural habit. As to varieties, there are none in cultivation comparable to the type. The yellow-berried *Rivina flava*, for instance, is hardly worth growing in comparison. From its character and habit, *Rivina humilis* is one of those plants that should never be grown in quantity in larger than 6-inch, 7-inch, or at the most 8-inch pots. Of these three sizes, the smallest are the best. In the few gardens where the graceful scarlet-berried shoots are appreciated for the decoration of baskets, vases, and dinner-tables, it is a good plan to furnish the gable end of plant stoves with *Rivinas* planted out in two parts of fibrous loam and one of leaf-mould. The plants grow, flower, and berry freely in a heat of from 65° to 75°. Permanent plants of this sort look very attractive in winter when covered with scarlet berries, which have earned for the plant the popular name of *Bloodberry*, or *Rouge Plant*. These planted-out stock plants are also exceedingly handy for furnishing cuttings at any season of the year, and also have a very striking effect when their shrubby stems and berried racemes are allowed to scramble up pillars or rafters, and droop back, which they mostly do, in abnormal profusion towards the floor.

Dwarf bushes on side or overhead brackets are also very bright. The *Rivina* also readily lends itself to growing into loose pyramids. "T." is quite right in saying the plants are most freely propagated either from seeds or cuttings. However, most growers prefer cuttings, as saving a good deal of time and favouring a more uniform and more densely berried plant. D. T. F.

— "T." (p. 299) does well to notice this too-little-grown plant. Its value is enhanced by its being in full beauty at a somewhat dull season of the year. As "T." observes the plants, though doing well enough in a warm greenhouse up to a certain date, must be removed to warmer quarters before cold nights have turned the leaves yellow. When the pots are full of roots, a liberal supply of weak liquid manure is necessary to prevent the lower leaves giving way. In a conservatory the temperature of which can be maintained at from 55° to 60°, this plant is most serviceable placed amongst Ferns or graceful foliaged plants. I have seen it used with capital effect in dinner table decoration, as, for instance, when a *Coccos* is placed for a centre-piece, small plants

Rivina being arranged in a mound of Moss at the base, this being furnished with light Fern fronds. The plants are useful for placing in receptacles in the drawing-room, but they must not be left there more than a few days, or the berries will fall.—NORWICH.

The Eucharis mite.—A good many remedies have at different times been prescribed for the dreaded Eucharis mite, some of which take a good deal of preparing. Mr. Webb, the gardener at Kelham Hall, Newark, has found the best and most lasting cure in merely sprinkling fresh soot on the surface of the soil and watering it in. Only a little is applied at a time. A good-sized batch of plants affected with the pest being so treated was cleared of it in a very short time, the foliage afterwards becoming vigorous and the colour improved.—C.

Double-flowered forms of Begonia semperflorens.—In his autumn catalogue M. Lemoine announces the disposal of four varieties of Begonia semperflorens with double flowers, which are in all probability destined to become the forerunners of a popular class, as several single-flowered varieties of this Begonia from the same source, particularly *B. semperflorens gigantea* and *carminea*, are very largely grown, and now double flowers are once obtained great improvements on these early forms may reasonably be anticipated, especially when the results in the tuberous-rooted section are borne in mind. The varieties sent out at the present time are *Boule de Neige*, clear green foliage, large double flowers, pure white, sometimes slightly edged with rose in the open ground, stamens clear yellow; *Gloire du Montet*, foliage slightly bronzed, flowers double, petals imbricated, rose-lake, buds carmine; *Nancy*, leaves deep green, flowers medium size, double, soft rose, stamens chrome-yellow; *Triomphe de Lorraine*, foliage bronzed or reddish-green, flowers with imbricated petals of a carmine-cerise colour, with scarlet buds.—T.

Tree Carnations.—What a pity it is so many alike Carnations are sent out under different names. One is apt to buy a much lauded variety, watch its progress with interest until it flowers, when he finds out he has had it in his garden perhaps for years. Mme. Thérèse Francoe is now generally considered the same as Mrs. Leopold de Rothschild. This was to supersede Miss Joliffe, but on my first seeing it growing I did not think it would. It is of a somewhat wiry habit, and does not make grass enough to produce what a grower for market would call plenty of bloom. Still it is a useful Carnation for the private garden, and one thing in its favour is its long season of flowering, producing a few blooms late into the spring. It is very useful not only on account of its colour, but also size for button-hole work. I do not think the idea of some that the well-known scarlet variety *Alegatière* is wearing out is correct. Not long since I saw a fine lot of plants producing in quantity large, full, highly coloured blooms, very few having any trace of the white flake, and borne on long stems. Many now-a-days seem fond of giving heat to winter Carnations, but this soon weakens and spoils the stock.—C.

Saintpaulia ionantha.—There is a great sameness in the plants used for the margins of greenhouse and conservatory benches, and the choice of suitable plants for the position is generally confined to fine-foliaged plants and grasses, so that any addition, especially in the form of a free-flowering plant, to the list is acceptable. The *Saintpaulia* is just the plant wanted for this purpose, for it does best in small pots, is neat in growth, and lasts in flower quite late into the autumn. It is easily raised from seed, and though a little inclined to be miffy at first, though not so much so as *Streptocarpus* and some others that might be mentioned, it soon grows out of the delicate stage and becomes a charming little-flowering plant, quite out of the common. It may be grown in pans, several plants together or singly

in pots up to 6 inches in diameter, but it never is more pleasing than when grown in 3-inch or 4 inch pots, as its growth is very dwarf and suits a small receptacle best. The flowers of the type are deep blue, but there are at least two varietal forms—*S. i. celestis* and *S. i. rubra*—the former sky-blue and the latter ruddy purple. The plants like a little shade from bright sunshine and are quite at home in houses devoted to the ordinary run of flowering plants shaded to preserve the flowers as long as possible.—J. C. T.

ARUM LILIES TURNING YELLOW.

I QUITE agree with the remarks on the subject by "J. C. T." (p. 300) and of the causes mentioned. The undue mutilation of the roots at lifting time is calculated to do a large amount of injury—injury that cannot be easily or even quickly remedied, inasmuch as the plants have of necessity to exist on their stored-up energies till either new roots are formed or fresh root-fibres are produced on the main roots broken through lifting. This is always a drawback to the planting-out system, and its danger is naturally increased when the plants are very forward in leaf-growth before lifting takes place. It is evident "E. A. T.'s plants were vigorous before lifting was attempted, and, no matter how carefully the work is done, there is always a considerable loss of roots. I do not in the least understand why "E. A. T." placed his plants after potting "into a shed for a few days," for surely no more uncongenial surroundings than this could possibly be chosen for freshly-lifted and recently-potted plants. Robbed of light of the right sort, and what is equally bad probably, exposed to draughts also, I am strongly of opinion that the check causing the trouble began in the shed referred to—the very worst possible substitute for a cool greenhouse that could be conceived. Far better that the plants had flagged in the ordinary greenhouse, for then with the aid of the syringe recovery would have been more quick and more complete. The atmospheric conditions of air, &c., for these moisture-absorbing subjects are not easily imitated in a shed, and the chilling influence of such a place during many of the cold, frosty nights so recently and generally experienced would undoubtedly have an equally chilling influence on the plants. An excellent place for recently lifted plants of these Arums is a cold pit, and having given one good root watering at the time of potting, endeavour to maintain the foliage in a moistened state for several days. Over-much root-watering when the roots themselves are comparatively inactive is an error, and had the leaves been kept in a more or less moistened condition, the failure now complained of would possibly not have occurred.—E. J.

—Rottenstable-yard manure, which "E. A. T." says he added to the soil when potting up the Arums, is a most uncertain compound alike in quality and quantity. It might prove the most powerful stimulant, the most wholesome food, or an arid poison to the roots. Anyhow, the Arums did not need nor could they use it at that stage. Up to lifting, the roots had had ample supplies of food, we may safely assume. They were suffering if at all from a surfeit; they could not have had too little food. And then all of a sudden the roots were lifted and offered a new bait, compounded of a half, or a third possibly, of stable-yard manure. Is it any wonder that the roots failed to act and the leaves turned yellow? Wounded roots hate stable manure. Had some sweet leaf-mould been added to the loam there would have been no yellow leaves. If the Arums had been potted up at once in the soil that they had grown in through the summer all would have been well with the roots, and the leaves have remained as green as Leeks. It is always a mistake to offer fresh and rich food to lately disturbed or wounded roots. Better cut off the supplies by running a sharp spade round and under the Arums a week before potting them up. After they have got over the check incident to potting, it is easy to feed the roots or top by top-dressing or liquid manure to any required

extent. The plants were put into a shed for a few days. Who shall describe the cutting draughts, the heat or cold, the wetness, the parching drought, the light or darkness of the shed? The whole shed incident is one of mystery, and almost certainly one of dire mistake. It is not even recorded that they were sprayed overhead or watered at the roots. We are told they were well watered with plain water and kept in a greenhouse. But this was after they came out of the shed. Nothing is said as to watering or otherwise treating them before standing them in the shed or during their stay there. From the fact that all the plants, with one exception, are now looking sickly and turning yellow, and have never recovered from the potting which was done some three weeks ago, I have the strongest suspicion that the trouble arose in the shed.—D. T. F.

GARDEN FLORA.

PLATE 1194.

EVERLASTING PEAS.

(WITH A COLOURED PLATE OF LATHYRUS PUBESCENS. *)

ADMIRERS of hardy flowers cannot afford to overlook the Everlasting or perennial Peas. *Lathyrus odoratus*, the annual Sweet Pea, exquisite as it is in form and colour, and pleasing as it is because of its fragrance, cannot be used in all positions. Even if it could, our desire for variety would induce us to grow its congeners of perennial habit. The best known of the perennial kinds are *Lathyrus grandiflorus* and *L. latifolius*. In some districts the former is very common, almost, indeed, to the exclusion of the latter. In other places the position is reversed and the broad-leaved Everlasting Pea is more largely grown. Were I asked which of the two I prefer, I should decline to say. Each has its uses and its beauties as well as its failings, and both may be grown with advantage in our gardens. Descriptions in a contemporary a few years ago of three new Everlasting Peas from California led me to seek to make their acquaintance. This I did through the kindness of Mr. W. E. Gumbleton, who sent me plants of each, viz., *L. latiflorus*, *L. sulphureus* and *L. violaceus*. Unfortunately, none of these has proved a success in our climate, and I have not flowered them, although *L. sulphureus* survived for some two or three years beside a warm wall. I believe they have been a failure at Queenstown also, so that I fear we shall have to content ourselves without them. For hybridising I should, however, think these Californian Peas would be likely to prove valuable.

LATHYRUS GRANDIFLORUS.—The great fault of this, which has the finest flowers of all our hardy Peas, is its running habit at the root, which soon makes it obnoxious in some positions where it has been planted without full consideration. It is, I think, seen at its best rambling over a hedge or growing on a trellis, covering either with its fresh green leaves and its bright flowers. I know one of those cold, hard, unsightly iron railings still too often seen in gardens which is in summer beautifully draped with this large-flowered Pea, which veils its ugliness with bright colouring. It seems to me, too, that *L. grandiflorus* is less needful of sunshine than some of the other species. I know a hedge some 20 yards long which only receives a few hours' morning sun, and this is covered every summer with the large flowers of this Pea. Like others, it appears to prefer a poor and rather dry soil. So far as I am aware we have as yet no pronounced varieties

* DRAWN FOR THE GARDEN by H. G. Moon from flowers sent by Mr. S. Arnott, Carsethorn, Dumfries, N.B. Lithographed and printed by J. L. Goffart.

of this fine Everlasting Pea. It produces seed but seldom in the south of Scotland, so that one has had little opportunity of testing its constancy from seed. Rarely, however, is it seen with more than two flowers on a peduncle. Very distinct from *L. grandiflorus* is

L. LATIFOLIUS. It does not run at the root and is not so easily increased. Its flowers are produced in racemes, and in some districts it is well known as the Cluster Pea, to distinguish it from *L. grandiflorus*. It is a fine plant for similar purposes as its congener, and, like it, appears to enjoy the dry soil at the roots of a hedge or shrub. When once established in this medium it grows vigorously, and I have it on a sunny hedge in dry soil growing some 9 feet or 10 feet high, and freely producing large bunches of bright pink flowers. This colour may be said to be the normal one, but, unlike *L. grandiflorus*, the broad-leaved Pea has become subject to the law of variation, much to our gain. Some charming white varieties exist, and from these there are shades passing from blush to almost crimson, and a striped variety also. Some of these have received names, and seed has been sold of these

Lathyrus latifolius albus.

under name. I regret to say that the colours do not yet appear to have become fixed, and, much to one's disappointment, from the same packet several shades have come. Perhaps we may consider this a gain. Among my seedlings from Italian-grown seed is a pretty white one tipped with pink. Where well isolated from other colours, seed from the white variety, *L. latifolius albus*, yields a large proportion of white flowers. *L. latifolius* seeds very freely, but in order to prolong the bloom, it is desirable that the decaying flowers should be picked off. If anything,

L. TUBEROSUS is even more pronounced in its running habit than *L. grandiflorus*. It is also one of the plants for which slugs have a preference, and as it is less ornamental than either of the foregoing, I am quite pleased to be without its rose flowers. *L. tuberosus* is easily raised from seed.

L. DUMMONDI is a beautiful Everlasting Pea, and I recollect how pretty I once saw it on an old

gnarled Apple tree, where its bright carmine flowers looked exceedingly well among the branches. It is one of the Cluster Peas, and can be readily raised from seed. It is also of robust character and admirably suited for growing on hedges.

L. SUTHERI I have not grown, but have admired its rosy purple flowers. As it grows little more than 3 feet or 3½ feet in height, it is of value in places where the more rampant growers would be out of place.

Some seven or eight years ago I came across an Everlasting Pea named

L. ARMITAGEANUS in a catalogue. At Kew this is considered synonymous with *L. magellanicus* (Lord Anson's Blue Pea), and as I much wished to have this, I procured a plant. I have never seen the plant grown at Kew as *L. magellanicus*, and the last time I visited the gardens neglected to look for it. The description in the "Dictionary of Gardening" is, however, quite unlike that of the plant I have as *Armitageanus*, which is a poor-coloured and small-flowered Everlasting Pea. It may not be out of place to remark that the seeds generally offered as those of Lord Anson's Blue Pea are only those of the annual *L. sativus*. A Pea known as Lord Anson's was in cultivation in Ayrshire years ago, but Mr. James Service, of Maxwelltown, Dumfries, who knew it there, has ascertained that it is no longer in the garden in which it grew when he was there. The nearest approach in colour I have yet seen to a blue in the Everlasting Peas is in

L. PUBESCENS, figured in the accompanying plate. The pubescence on the stems and leaves it has been impossible to reproduce. The plant from which the flowers were cut was the only one out of several raised from seed which escaped the ravages of slugs when in a seedling stage. It was planted out in 1896, I think, against the s.w. gable of an outhouse and on a trellis. The soil is light and the position a dry one. It came into flower the following June, its sole protection in winter being a few old stems and branches of Michaelmas Daisies over its stems and roots. The same protection was afforded last winter. This year it came into bloom very early in June and continued in flower for some time, although my allowing it to seed this year shortened its flowering season. It is of a semi-shrubby habit, growing about 6 feet high here, and produces some of its shoots from the old stems. The seeds ripened this year, and it may save trouble to say now that they have passed from my hands by arrangement. I had an impression that I obtained the seed originally from Mr. W. Thompson, but I cannot see it quoted in any of his catalogues in my possession. The charming colour of this Pea, which is a native of Chili, will render it acceptable to many. Should it prove hardy with others, as one has reason to expect now that so many Chilian plants survive our winters, it will be an acquisition to our gardens, and may, moreover, be one of the factors in giving us colours and tints yet unknown in our hardy Everlasting Peas.

S. ARNOTT.

Carsethorn, by Dumfries, N.B.

Vitis inconstans.—Very lovely just now is this well-known creeping plant, and with all looking dull around it we admire it the more. The upper part is still of the brightest green, the centre of varying shades of red, the older leaves becoming a deep bronzy purple. All these shades are prettily graduated, and what looks fine at a distance is even more beautiful on closer inspection. Even in winter after the foliage is gone the delicate tracery of the clinging stems over old mullioned windows is charming. This creeper is one of the very best for hiding unsightly walls or for covering old mansions, its free-growing character enabling it to soon cover a large space, and what is of still greater importance, it thrives in any description of soil or situation. In very shady places it will not, of course, take on the same beautiful tint in autumn as it does in positions more exposed to sun and air, but even there

it is attractive. It is always best to give the young plants a start by digging out a couple of barrowloads of the old soil if worn out and replacing it with good new compost. They may be planted either in spring or autumn, the latter for preference. Young plants are easily raised from cuttings of the half-ripened shoots, these being taken about 6 inches in length and rooted in pots in a close frame in late summer.

THE WEEK'S WORK.

KITCHEN GARDEN.

CROPPING THE LAND.—Much may be done at this season as regards the preparation of the soil for next season's crops. With gardens of limited extent, and where there is a heavy demand, there cannot be the needed rotation of crops. Much may be done at this season to determine next year's crops and prepare the soil for the same. In my case, having a large acreage under cultivation, I can rest a goodly portion. By resting I mean giving an entire change of crop. By so doing one can always give more thorough cultivation. Garden land so soon sickens of such crops as Cauliflowers, Cabbages, or, indeed, any of the Brassicas, that it is well to change the quarters as often as possible. It is not possible in the case of sheltered borders. I have a border that has furnished early Cauliflowers for at least forty years. This is under a south wall with a glass range in front of the border. To get good crops I am obliged to occasionally give a good coating of fresh soil, and dress freely every autumn with lime, soot, wood ashes, or other materials. By doing so there is a good return. I always endeavour to study the summer crop, as this is important. I only grow salads or such plants as are soon cleared, so as to allow of good cultivation for the winter subjects. In many gardens a change of crop may be given, even with sheltered borders. Peas or early Potatoes may follow Cauliflowers. Open quarters now cleared may be dressed for the next crop. I always determine now what crop shall occupy the quarters next season, as, by so doing, the work is easier. Roots do not need fresh manure. These may follow a crop that has been well manured. Onions may follow early Celery if the land is well exposed. Celery will follow early Cabbage, which next autumn will occupy the Onion quarter. Some vegetables, such as Brussels Sprouts, need deep rich soil. Peas, French and kidney Beans need generous treatment. The heavy soil should be reserved for Broad Beans and for summer crops needing a holding soil.

MANURING SOILS.—With the ground in better condition after the much-needed rain, the cultivator will do well to prepare the same for next season's crops. At no time of the year can the soil be improved so well as at the present. I am greatly in favour of autumn digging, especially in light soils, as if turned up roughly now it is sweetened for the crops. Many who are anxious for the best results have been disappointed by trenching some soils too deeply. In many gardens the subsoil is so poor that when deeply trenched and brought to the surface it does harm, as the roots do not reach the better or deeply buried soil. Trench or double dig such soil, but do not bring the poor, inert soil to the surface: keep it where it is, place the manure between the two spits, and dig the lower one as deeply as possible. Where animal manure is none too plentiful, my advice is to dig now and feed in the spring, using fertilisers freely during the growth of the crop. Heavy clay land needs more care, much depending upon its condition, the crop it is to carry, and other details, as some very wet, heavy land is best left till needed for the crop. Many soils are badly infested with wire-worm, this attacking the crop just when least expected. For this I have found nothing better than a good dressing of gas-lime at this season, spreading it, if fresh from the works, on the surface for a few days before digging in. A few

years ago I had an instance of the great havoc wireworm caused in a short time. A lot of turf was taken from an old pasture to enrich an old kitchen garden. The turf was a mass of wireworm, and for two years the crops were poor indeed till gas-lime was used in good quantities in September and the soil not cropped till spring. Ordinary lime, soot, and wood ashes are excellent. These may be used and a crop follow immediately. I fear after the drought last summer garden pests will be so numerous that it will be well to pay more attention to their extermination. I have suffered badly from elbbing in several of the Brassicas, and the dressing advised for the wireworm will apply here. Gas-lime used in moderate quantities in the autumn and winter will elzar the soil, and at the same time if charred refuse, old mortar rubble, or lime can be given as a top dressing, it will do more good than rank animal manures. Land cleared of exhausting crops that root deeply will be greatly benefited by being turned up roughly before winter, and in manuring it will be well to study the crop to follow. Now is a good time to make use of any good soil there may be at hand. This spread over the surface after digging will be beneficial. A good supply of decayed manure should be at hand. Other manures should be turned and prepared, and if at all dry, liquid from stables will cause rapid fermentation.

PROTECTING TENDER PLANTS.—To eke out the vegetable supply it will be necessary to protect those plants at all tender. It is full early to lift Cauliflowers; indeed, I do not advise doing so, as owing to the drought the growth of these plants is much later than usual. I find it a good plan to tie up rather loosely the leaves over the flowers. This will ward off several degrees of frost and prevent the heads being spoiled. Peas grown in frames so far have done well. These need ample supplies of air, so that free ventilation is necessary both night and day. If mildew is at all troublesome dust with sulphur. French Beans will be benefited if more warmth is given. It will be advantageous to cover the glass at night if the frames are much exposed. So far there has been no break in the supply from open borders. These will continue to bear if given protection at night. I think Beans grown thus or in frames far more valuable than those forced hard, as the crop of the latter between now and the end of the year is not a profitable one.

STORING ROOTS.—In many gardens the orthodox way is to lift Carrots at the end of this month and store. No matter how mild the season, the roots are lifted in full vigour, the result being they grow out and lose flavour, and by the end of March, often earlier, are useless. My advice is to leave the roots in the soil if the land is light and well drained; if otherwise, I would lift much later and place in a clamp in preference to a dry store. Carrots are quite hardy. For the past half dozen years I have always sown in July for winter and spring use, and the plants have not suffered during severe weather. It may be said that in severe weather it is a difficult matter to lift roots. This I admit, and it may be well to be prepared by lifting a few in advance, or by covering the surface with litter. Beetroot is not nearly so tender as often thought. I allow mine to remain in the growing quarters till November is well advanced. The greatest difficulty is that too much moisture causes the roots to split if they are at all large. It is much better to store in soil or sand if under cover, as if the air can circulate round the roots they shrivel badly. The best store is an underground cellar just free of frost. Such roots as Sal-afy and Scorzonera suffer more from wet than frost, and it is necessary to lift on this account. There need be no hurry, as the plants are still growing freely. These roots need much the same treatment as Beetroot in the winter, though in some favoured localities they will do well in the open ground. Turnips, I fear, in many gardens are none too plentiful this autumn. In my case, owing to the drought, it was a difficult matter to get the seeds to germinate. Turnips do much better in the open

ground for some time yet, though it is not advisable to leave very large roots. These may be clamped, as they soon lose flavour. I do not advise large Turnips for storing or winter use. Those the size of a cricket ball are much the best, and unless the supply is short, I would place coarse ones on one side. The yellow-fleshed kinds winter grandly, and in very severe winters I have found the white roots keep well by merely drawing up soil round the roots. S. M.

FRUIT HOUSES.

FRUIT TREES IN POTS.—These, which if potted when advised, will now have become settled down in their fresh pots, with root-action again on the move. In my own case they are promising well, the wood showing every sign of being fully ripened. The leaves have all fallen during the past ten days, having assumed prior to falling those beautiful tints one likes to see. The trees are now housed owing to the rather continuous rainfall, too much of which is decidedly prejudicial to the early-forced plants in particular, as it also is generally to the rest if care be not taken. For the present the early trees are stood rather closely together from want of room, but this is immaterial with a thorough ventilation always going on around them. There is a slight warmth in the pipes to prevent a too humid condition of the atmosphere. After the soaking these trees had before being housed they will not require any water for some time to come. When it is seen that they are becoming dry on the surface, they may be examined and sounded, paying the closest attention to those in proportionately small pots. If these trees are not started before the new year or thereabouts, it is a good plan to work some dry stable litter in around the pots when the trees are brought in. This will prevent them becoming dry upon the surface when, perhaps not so, lower in the hall. Do not do any pruning yet, but rather leave it until starting-time, and then only foreshorten such shoots as have prominent fruit-buds at the bases of the shoots.

LATER TREES.—Those from which the crop has not long been taken should all be potted up by the end of this month, or at the latest by the middle of November. I hope to complete it before this is in print if possible. The same course is pursued as with the early ones in every particular as regards potting and soils, but these later trees will, as soon as they have had a good watering, be placed in a sunny position. Mine, from want of room, are stood upon the Vine border, no more water being given, therefore no harm can well be done, the pots being stood upon bricks to keep them well off the soil with stable litter closely packed between the pots, but with more around the outer ones, against which boards are placed for greater convenience in keeping the litter in its place. Here the trees will remain until showing signs of making a move in the spring, being safe against harm from frost. If I had an absolutely cold house without any piping I should prefer to house these also, but it is not of very material consequence. Retarding in the case of late trees is what has to be aimed at, and this is accomplished by keeping them outside. If trees have been lifted from the borders and transferred to pots, then it is a safer and better plan to house them for the first season.

EARLY FIGS IN POTS.—These have also been housed for some ten days or so, owing to the rains and in order to save any further trouble with them as regards protection when frosts come. A selection will now at once be made of the most promising-looking plants for first early forcing. These will be calculated as started from November 1 in order to have ripe fruits by March 1. This is earlier than usual in some establishments, but as the Fig is highly esteemed, the plan is adopted, knowing that some amount of risk is run. In selecting St. John and Pingo de Mel, however, the risk is reduced to a minimum, as these varieties are not nearly so much disposed to east their fruits as other and older kinds, valuable

for later work as these latter are, but the two just named are by far the best for first early forcing in pots. I do not advise either of them to be planted out, being doubtful as to their behaviour under such conditions. They are vigorous growers in pots, but owing to restriction at the roots, they succeed admirably. Planted out they would in all probability grow too luxuriantly unless in quite a restricted border. The same treatment as that accorded to early Vines in pots will be followed, the syringe being used freely. For the first fortnight no bottom-heat will be given, and then only to a moderate extent before another fortnight has elapsed. The night temperature will range at 50°, and that for the day at 65°, and 70° when favourable. A careful sponging or brushing with a soft brush will be resorted to, using Gishurst compound (or any other insecticide if that be not available) at the specified strength as a safeguard against red spider and possibly a little brown scale. As no mealy bug exists, stronger measures have not to be adopted—this of itself is a comforting assurance. Where the younger wood, *i.e.*, the shoots made after the first or second stopping last season, is not well studded with fruit-buds, is weakly, or not well ripened, I shall prune it back. In doing this it does not imply that any risk as regards a crop is being run, as these Figs will push forth their fruit from buds lower down. Indeed, I believe a plant of either of these Figs might be pruned all over and then a crop be had, so prolific are they under favourable conditions.

FIGS FOR LATE FORCING.—These are still bearing some good fruits, and will continue to do so for another month or so. The most conspicuous kinds now are Nebian and Bourjassotte Noir. Negro Largo, which has been excellent, is nearly all gathered. The two first have still good crops on them, which with warmth will finish well. Being so very distinct from each other, these two varieties afford quite a contrast. Great care as regards moisture has now to be exercised to prevent cracking. The night temperature averages at banking-up time 68° to 70°, with 10° to 15° increase by day. Those of the late batch which have been cleared of their fruit are in my case being kept in a light house at a temperature of 5° less than that just given. This is done with a view to thoroughly maturing the wood; a dry, warm atmosphere with a free ventilation will accomplish this. As the leaves fall the plants will be moved to a dry vinery for a time before being kept absolutely cool.

EARLY TRAINED FIGS.—These should receive attention as soon as possible, so as to be in readiness for starting when it is customary to do so. If need be this may be done with safety by December 1. Cleanse the wood thoroughly as previously advised, having done what little pruning may have been found necessary, bearing in mind that it is an easy matter to overcrowd Fig trees, but, assuming that care has been taken in this respect during the past season, there will not now be any great amount of wood to operate upon. If it can be so arranged as to paint all the woodwork and wires once every year, so much the better, but if not, then give it a good washing down. If syringed first with a weak solution of Bentley's paraffin oil insecticide the dirt upon the woodwork will be easily removed. Top-dress the borders wherever possible, using a good proportion of lime rubble or bone-meal, either of which will serve a good purpose. HORTUS.

The break up of the drought.—At last rain has fallen in sufficient quantity to moisten the earth some inches in depth. It will prove of inestimable benefit to all green crops in gardens, although too late for root crops on the farms. The barometer began to fall on the 14th, the wind changing at the same time to E. and S.E., and on the 15th it rained for a few hours. It then cleared up, but rain came on again at night. The fall was heavy throughout the night and the early hours of the morning, and on the 16th there was a further fall in the barometer, the wind still

remaining in the same quarter, which betokened that heavy rain was close at hand. The prediction was verified towards eight o'clock in the evening, when it began to rain heavily, and continued doing so without intermission until nine o'clock on the morning of the 17th. The soil being in such a dry state, it has absorbed nearly every drop which fell, and it may safely be stated that but little or none has run to waste. All the Brassicas have received a good cleansing, of which they stood in great need, for I never in all my experience remember to have seen them so full of aphides before. Coleworts and Cabbage set out for early spring cutting already look the better for the rain, and it is to be hoped that they will now grow away and make up for some of the lost time. Celery and Leeks will benefit considerably by the abundant fall, but the sooner all late Potatoes are lifted the better. Carrots and Parsnips, it is feared, will split under the influence of the sudden accession of moisture, but in my case the matter can be remedied by lifting the roots, they being sufficiently large for general use. Turnip-rooted Beets will also be better lifted and clamped, otherwise there will be a tendency towards second growth. Strawberry plants will now be able to make some amount of growth before the winter sets in, and the foliage of fruit trees looks fresher and cleaner. Although rain has fallen abundantly, we must wait for further supplies before lifting and planting can be commenced.—A. W.

NOTES ON PEAS.

I CONSIDER Autoerat, Duke of Albany, Eureka, Satisfaction, Mainerop, and Improved Ne Plus Ultra the best. The two first-named grow more largely than any other. Autoerat can be depended on to give a continuous supply for a very long time. The pods are not so long as those of many of the other sorts, but the Peas are very large, of a dark green colour and delicious flavour. The above six sorts are all very heavy croppers, resist mildew better than most sorts, and all have a splendid flavour. I consider the best early sorts to be Ringleader, Improved Ringleader, William I., and Early Giant. Improved Ringleader is a stronger grower, more prolific, and the Peas larger and better flavoured than in the type, but it is about ten days later. For mid-season, all the sorts named are excellent. To these may be added Veitch's Perfection, G. F. Wilson, Fillbasket, and Fortyfold, good old sorts, but small compared with many of the newer varieties. To yield a supply into the late autumn, Ne Plus Ultra is, in my opinion, the best, although most of those mentioned for midseason do very well if sown at the proper time, which, I consider, is from the middle of May to the middle of June.—J. IRONSIDE, *Blackadder Gardens, Edrom, N.B.*

— My favourite Pea for an early crop on a warm border is Chelsea Gem, with William I. to follow. I grow Sharpe's Queen, Veitch's Mainerop, and Stratagem for midseason, with Autoerat and Ne Plus Ultra for a late crop. For a late supply I make a sowing of the two last-named varieties the last week in June. These keep up a supply until October, should the weather be favourable.—W. ANDREWS, *Tringham, Truro.*

— The earliest and best as grown here are Chelsea Gem, William the First and Extra Early Selected: second early: Gradus, Criterion, Prodigy and Autoerat. For latest of all I sow, in the middle of July, Ne Plus Ultra, Late Queen, Sturdy and William the First. The last, although an early Pea, often stands the autumn better than any other variety, being a strong grower and, as a rule, free from mildew.—J. SMITH, *Montmor, Leighton Buzzard.*

— Out of the many kinds of Peas now in commerce selection is most difficult, where so many are so good and the returns will differ in a remarkable degree no doubt. I have been growing in two diverse places in Surrey twenty good but not tall varieties, and in each case the results have been the same. All have done well, and

choice for crop or excellence is extremely difficult. A special requirement of Peas now, however, is that they be green, both in pod and Pea; that the latter be closely set in the pod; that the pods open and shell easily, and be not of the broad, puffed order, as these never open well. Generally the greenest Peas give the sweetest and best flavour. A fine selection of dwarfs is Chelsea Gem, or William Hurst; English Wonder, really a wonderful and delicious dwarf; Daisy and Dwarf Defiance. Of taller Peas, Gradus, though not a great cropper; Early Giant, remarkably fine; Senator, Peerless, Sharpe's Queen and Gladstone are hard to beat, but Autoerat, 4 feet, may be added. Of tall Peas—of which I have grown none, but have seen them elsewhere—I have found none better than Alderman, without doubt one of the finest and best flavoured tall Peas in commerce. Judging plates of raw shelled Peas recently, I found one much sweeter and softer than the others, and it was placed first. Then I turned to the Peas in pod and found the same exhibitor showing Ne Plus Ultra, but the pods were small. That showed that in the matter of sweetness and softness none of the new Peas excel that famous old variety. It is, however, small of pod and a moderate cropper. Were I growing three Peas only, early, midseason and late, I should sow Senator, Sharpe's Queen and Late Queen or Gladstone, as both are fine late varieties. From the middle to the end of June is a good time to make a sowing for an autumn supply.—A. DEAN, *Kingston.*

— The kitchen garden being so small, I have little room for trying new kinds of Peas, and depend largely on old and well-tried varieties. I have given up all the round-seeded forms with the single exception of William I., which in most seasons produces an enormous crop of Peas of fair quality only. In place of Ringleader I grow May Queen, a useful kind of exceptional quality and very free bearing. Chelsea Gem is one of the most useful of dwarf kinds and takes up little room, so I sow it freely. Sharpe's Queen is an excellent midseason Pea, and so is Yorkshire Hero, a kind that seems to hold its own in the very driest seasons. East Anglian is a free-bearing local kind. Duke of Albany is of excellent quality in July and early August, but is soon over. Stratagem is a good free-bearing Pea, well filled up and constant. Autoerat is the best late Pea I know, and I grow nothing else for the latest supplies. Before this fine kind was sent out I sowed the small kinds, such as Sangster's No. 1 and others, until the end of July, but my latest sowing now is Autoerat about the first of the month. Sometimes, owing to very dry weather, this is a failure, but usually when the cooler autumn weather sets in the pods are produced in greater or less quantities until the middle of October.—H. RICHARDS, *Cobham Hall, Burg St. Edmunds.*

— The best Peas I consider are Chelsea Gem, William Hurst, Daisy, Criterion, Duke of Albany, Veitch's Mainerop, and Autoerat. I do not think one need multiply varieties, as, like other gardeners, I grow several other varieties just to test them. For instance, I grow Veitch's Perfection largely, but this season it has not done well, neither has Sharpe's Queen. The former, as every gardener knows, is a grand Pea in a season which suits it. Ne Plus Ultra is a fine Pea, and which I also grow extensively. It is, however, altogether too late. In some seasons it does well, others not so. Autoerat is more reliable, although not of such high quality. If I were bound down to three Peas, they would be William Hurst, Criterion, and Autoerat. As a rule, the middle of June suits this district for sowing for an autumn supply. I commence sowing from the middle of May up to July 1 for late crops, at intervals of ten days.—A. YOUNG, *Witley Court Gardens, Storrport.*

— The Peas I consider the best are Exonian, William the First, Senator, Duke of Albany, Dr. Maclean, Dwarf Marrowfat, Autoerat, Goldfinder, and British Queen. For early Peas I sow Sangster's No. 1, Exonian, and William the First.

For succession crops I sow four sorts at the same time, viz., Senator, Dr. Maclean, Dwarf Marrow, and Autoerat. Dwarf Marrow and Autoerat come in after the others, and ensure a supply in succession. For late autumn supply I sow British Queen or Goldfinder about the second week in June as single rows, and the second early sorts, such as Senator and Harrison's Glory, up to the first week in July. The autumn crops require protection from birds.—JOHN GARLAND, *Kilberton, Eector.*

— The earliest Pea with me was Extra Early, followed by Chelsea Gem and William the First. The best midseason Peas were Veitch's Perfection, Supreme, Yorkshire Hero, Sturdy, and, last of all, Ne Plus Ultra. About June 21 I find a good time to sow the last Marrow Peas. There are many other good kinds of Peas, but it is impossible for most gardeners to grow a large variety of sorts. If only three kinds were needed for a garden, I should choose William the First for an early, Veitch's Perfection for a midseason, and Ne Plus Ultra for a late kind.—A. HARDING, *Orton Hall Gardens, Peterborough.*

— The varieties I rely upon for a season's supply are Chelsea Gem, Criterion, Duke of Albany, Dr. Maclean, Chelsonian, Veitch's Perfection (true stock), Autoerat, Mainerop, and Ne Plus Ultra. The above are all good croppers and good in flavour, Criterion being the very best in flavour I know. The best early for sowing in pots and planting out is Chelsea Gem. The best early for sowing in the open ground in January or February is Extra Early. The best midseason varieties are Criterion, Veitch's Perfection, Mainerop, and Duke of Albany; for late supply, Autoerat, Ne Plus Ultra, and Chelsonian. I make the latest sowing on or near June 20, and only in one season during the time I have been here have I failed to pull abundantly from sowings made on that date. Personally I do not recommend the sowing of Peas in trenches over manure unless it is on poor, shallow soil, preferring to manure and thoroughly pulverise the whole body of soil, sowing the seed in the ordinary way about 2 inches deep. When sowing in January or early in February I sow practically on the surface, drawing earth over the seed in the form of a mound. In this way I find very few seeds are lost through decay.—J. TUNNINGTON, *Ripley Castle Gardens, Yorks.*

— The names of the varieties of Peas in cultivation are legion, and bewildering to many. I consider the following varieties, for cropping and quality, amongst the best: William the First, Gradus, Duke of Albany, The Baron, Veitch's Perfection, The Duchess, and Ne Plus Ultra. I consider William the First the best early, Duke of Albany the best midseason, and Ne Plus Ultra the best late variety. About the end of May is the best time to sow Peas for an autumn supply.—A. PETTIGREW, *Castle Gardens, Cardiff.*

— The favourite Pea for early use and growing upon warm borders is Chelsea Gem. This is moderately dwarf, bears very freely, and is of good quality for an early variety. It is succeeded by Exonian and William the First, both of which are hard to beat. Fillbasket, Telegraph, and Duke of Albany form the bulk of mid-season kinds. Champion of England, Ne Plus Ultra, and Autoerat are sown in the order named for late crops. Ne Plus Ultra for many years was the only sort grown for late use, and even yet I do not consider it surpassed by any other for good quality and productiveness for a long season. Autoerat being much dwarfier finds favour in this respect. The seed for latest crops is sown during the first week of June, and although early and second early sorts have been tried by sowing them about the middle of the month, I have not found them worth the labour of so doing, as the sorts named can be had in quantity until the middle of October, and in favourable seasons even later. They are of superior quality to early sorts at that date. One point in the cultivation of late Peas as carried out here differs from that of many, viz., the manuring of the ground. Instead of sowing

in well-manned trenches, a piece of ground that is well exhausted of manure is selected, and after being well dug the seed is sown and no stimulant applied to the crop at any stage. Proximity to the sea necessitates this, as the moisture-laden atmosphere of the autumn months would cause such rank growth, and the Peas would grow to such a height that it would be impossible to keep them upright. Once the top part of the haulm falls over, the rows are greatly damaged, and the weight of crop lessened thereby. I have always observed that Peas which make a sturdy and not over-vigorous growth bear the best and heaviest crops, and are of course the easiest to cultivate.—JAMES DAY, *Gilfooy House, Garlistown, Wigtownshire.*

—The Pea that has gained most favour with me here is Williams' Emperor of the Marrows, a type of the old British Queen. Duke of Albany is also a favourite, but I consider the former the better flavoured and heavier cropper, and I get a longer succession of young Peas. I seldom sow any early variety but William the First. I do not, perhaps, get it in so soon by a few days as I should do some of the other early varieties, but I think the great superiority of this variety over the other early kinds more than compensates for a few days' loss of time. For midseason I still prefer the old British Queen, Magnum Bonum, Williams' Emperor of the Marrows, and Duke of Albany. Ne Plus Ultra is also a great favourite with me both for flavour and appearance. For autumn use I depend on Premier and Veitch's Perfection. I never sow later than the last week of May.—W. MARCHAM, *Wentworth Gardens, Virginia Water.*

—The many additions to the list of Peas introduced by the leading seedsmen have a tendency to lower the value of some of the old and well-tried sorts, yet in spite of this there are a few which still claim a place, even in the most select list. The early rounds, however, are losing ground since the early and hardy race of marrow Peas has become better known and proved. For growing on narrow borders for the earliest gathering I have not found a better than Chelsea Gem; Wm. Hurst, another dwarf variety, being very good. May Queen, Gradus, and Earliest Marrow are excellent for early sowing, and, being hardy, can be sown on warm borders as early as is usual with the round varieties. I have not proved it myself, but Early Morn I have heard good reports of by others. Eckford's No. 1 is an improved William I., growing to a height of 5 feet. When

has a future before it, the large size of the pods, its freedom in bearing, and the dwarfness of the haulm are all points of importance, particularly where a large supply is expected from a garden of limited size. Sharpe's Queen, Shropshire Hero, Pride of the Market, The Echo, and Heroine are all good and reliable second earlies of dwarf

is by this practice regular till autumn rains and frost put an end to them. Drainage, altitude and exposure regulate the Pea season to some extent.—M. TEMPLE, *Carron, Stirlingshire.*

—I do not see the advisability of cultivating an extensive variety, as with periodical sowing a succession of first-class Peas may be obtained. I

Stone seat, *Dropmore.*

Log seat, *Tresserve.*

cooked it is a very deep green, and the quality first-rate. Holloway Rival, a second early, is the most prolific marrow Pea I have grown, the haulm, which reaches from 3 feet to 4 feet according to the season, being literally covered from the ground upwards. The pods are filled with large Peas, and the flavour good. Daisy undoubtedly

growth. In taller kinds, Criterion still commands a high position because of its rare quality and free bearing. Critic, of more recent introduction, will gain favour as it becomes better known. Its pods, which are large, give Peas of the largest size, fine in quality, and freely produced. Epicure is a Pea of great merit, and, like the last-named, produces fine pods in plenty. Autocrat I depend on for late crops in the open quarters, and Chelsea Gem for borders. For autumn use the first-named is sown at ten-day intervals during June. These are ready for gathering from the middle of August onwards, according to the weather. Birds, particularly hawfinches and sparrows, are usually very troublesome. Chelsea Gem is sown on a border up to the middle of July, so that nets can easily be placed over it.—W. STRUGNELL, *Road Ashton.*

—American Wonder and Chelsea Gem have both been of great excellence; Gradus and Criterion, among 4 feet high early Peas, have been first-rate in every respect; Dickson's Favourite, Duke of Albany and Dr. Maclean are unsurpassed in this locality for second crop: Autocrat, Veitch's Perfection, and Ne Plus Ultra stand high as latest kinds; Sutton's Defiance sown late is a free-cropping dwarf with large well-filled pods of the finest flavour. To give a good supply of Peas of best quality, I do not know any which can surpass those I have enumerated. I begin the Pea season by sowing a good dwarf in boxes of turfy loam and leaf-mould, covering with fine soil. They are kept free from frost and well hardened before being planted out, when they are protected by mats on hoops when the weather is frosty. I gain about ten days by this practice, and sow from January every ten days in moderate quantities, to prevent waste, till the first week of June; a very early sort may be sown a fortnight later. The supply

sow for April picking in pots and cold houses American Wonder and Sutton's Forcing as the best, this latter Pea being far better than American Wonder, but not so early by about eight days; following these in the open with Excelsior and Harbinger, a Pea much appreciated for early work, having a good hardy constitution, large in size, of a beautiful green colour and delicate flavour. Following Harbinger are Exonian or Stratagem. For main crop and onward I grow Dickson's Champion and Favourite, Dr. Maclean, Duke of Albany, G. F. Wilson, Supreme, and Senator, and for late use, Autocrat and Ne Plus Ultra. Many of the newer kinds, I find, lack that delicate flavour necessary for the table.—J. LEE, *Gipsall Hall, Leicester.*

SEATS IN GARDEN AND PLEASURE GROUND.

THESE are among those things that tell something of the thought given to a garden. The modern cast-iron seat is about as bad as it can be, and we cannot say that the wooden seats of the English garden are much better. There used to be a simple kind of iron seat made many years ago which was much better, and with some kind of lattice-work over it did very well. Sometimes a very good Oak seat may be made, with the feet and supports only of iron, with laths placed on the iron frame. Of our own woods, Oak is the best; stout heart of Oak laths screwed into a simple iron frame without ornament make a good seat. They are best without paint, in the natural colour of the wood. No seat is so good as one of good stone, simply designed and strongly made, and in our country one objection to stone is met by the use of a mat or light lattice-work in Bamboo, or split laths of Oak held together by cross pieces and placed on the top of the stone. In Italy and France one often sees good stone seats, and there they are not expensive. Some of the French seats are simple and good in

form, and, painted a nice carnation-leaf green, they look very well. One of them at Warley Place is figured in our cut. Bamboos, which come in such quantities now in the sugar ships, might be more used for making pretty garden seats. Sometimes old tree stumps help to make useful seats, and the bole of the tree, if cut, makes a very good rustic seat. Where stone is plentiful, as in many hill and other parts, it is often easy to make useful seats out of blocks of stone in rocky places. Of this sort we noticed some pretty examples at Castlewellan and the rocky district around. Occasionally there are about country houses stone steps which with a little care can be made into very good garden seats.

ORCHARD AND FRUIT GARDEN.

MILDEW ON VINES.

In some places mildew appears to have been troublesome this season, and in one or two instances crops of Hamburgs have been in a great measure spoiled. The best of culture will not always prevent attacks of mildew, but it is in the power of everyone to stop its progress so that the loss is reduced to a minimum. It is where plants are grown with Vines that mildew is most to be feared. It frequently happens that Ferns and things of a similar nature, and which delight in shade and moisture, are grown to a considerable extent in amateurs' vineries. In dull weather, when but little air can be admitted, and when the floor of the house should be kept as dry as possible, the plants have to be frequently watered. The close, damp atmosphere which prevails during the night is favourable to the increase of mildew, which, if not dealt with on its first appearance, will spread with great rapidity over the house. It will, I think, rarely be found that mildew appears simultaneously in various parts of the structure. In nine cases out of ten it originates in one of the corners of the house or close to the bottom ventilators, for, although a close, damp atmosphere will induce an attack, it is equally certain cold draughts of air will bring it on. I had this spring a convincing proof that cold currents of air are alone sufficient to cause mildew. The only Strawberry plants that were attacked stood directly opposite a broken pane of glass. It was but a small opening, and it was curious to trace the passage of air from it to the ventilators above. In a direct line all the leaves were attacked, and in no other portion of a house 100 feet long was there the least sign of its appearance up to the time that the fruit was gathered. I, of course, took prompt measures to destroy the fungus; had I not done so, in the course of ten days or so I should have seen the white patches in all parts of the house. In eight seasons out of ten, mildew makes its appearance on my Hamburg Vines. It invariably comes on a couple of Vines near the door, and if I take it in time, I rarely see it in any other part of the house. The door faces the east, and when open for watering or for any other purpose the cold wind rushes in at times directly on to the Vines just at that end. At the opposite end, where there is shelter from cold winds, I have never known mildew appear. I am, therefore, justified in taking for granted that to the parching air acting directly on the tender foliage I may attribute the presence of this pest on my Vines. In the case of inside borders, where watering is systematically practised, there is but little danger of the soil becoming over-dry, but in a time of heat and

drought there is some danger of the Vines suffering in this way.

In districts where the drainage is free, the soil will get quite dry to a depth of 2 feet or more. This happens just when the berries of Vines which ripen off their crops during the hottest months of the year are swelling up freely, and this is the time when they are most likely to be attacked by mildew. Dryness at the roots is a fertile source of evil, bringing on an attack in the course of the growing season of either mildew or red spider. In the case of outside borders one or two good soakings will be sufficient, but inside borders will, when the Vines are well established and bearing heavy crops, require moderate waterings at frequent intervals. One of our largest Grape growers for market waters his late houses about every ten days, just stirring the surface, and in the course of the summer giving several top-dressings of some concentrated manure. The main point is to keep a sharp watch from the time growth gets fairly active and deal with the fungus the very hour it is perceived. I keep some yellow sulphur and a fine muslin bag in the house, and dust both foliage and berries the instant the disease shows itself. In this way it is soon stamped out and loss and anxiety avoided, but if the disease is allowed time to spread it will be next to impossible to rid the place of it. Vines that have been planted a number of years and which have few fibrous roots are more liable to be attacked than younger ones. The roots are so deep in the soil that they are in a great measure beyond the influence of sun and air; neither can they be liberally fed as is practicable with Vines that have an abundance of active roots near the surface. It is false economy to keep such Vines; far better root them out and re-plant young healthy canes in fresh compost. J. C. B.

Brunswick Fig on open wall.—This is seldom seen bearing well on open walls. I was lately pleased to see it thriving grandly in this position. It was occupying a south wall 14 feet high and from 30 feet to 35 feet long. At the time of my visit (the end of August) there was a splendid crop. The tree was probably fifty years old. I have found this kind unsuitable for planting in the open in heavy soils, as it grows strong and does not ripen its wood. Where it does well it is a most desirable kind.—J. Crook, *Fordes Abbey*.

The Dartmouth Crab.—Those who are anxious to add interesting features to their pleasure grounds should not overlook the above Crab. For weeks past several trees here have been greatly admired, and they will retain their beauty until a sharp frost or high wind robs the long and graceful branches of the mass of highly coloured fruit. The kitchen garden I do not consider is the most desirable position for these trees, as there are so many other parts of the garden where they could be used to better advantage, viz., in the mixed shrubbery and pleasure grounds. Even as a lawn tree it could not possibly fail to please, as it would prove no less interesting in early summer when covered with delicate bloom than later in the season, when the branches are almost borne down with the weight of deep, richly-coloured fruit. There are many trees and shrubs now used in such positions certainly much less ornamental than this and others of the Crab section of fruit trees. Of course, to see the trees in full beauty they should not be subjected to pruning of any kind, which would result in restricted growth and few fruit—a practice often followed so unwisely in the orchard. The habit of the tree is naturally spreading, and the branches, being situated some distance apart, become studded with flower-spurs their full length, and when the trees attain a good size

each branch forms as it were long ropes of fruit. The best form of tree is a standard with a stem not less than 6 feet. The lower branches naturally become pendent with the weight of fruit. In another important way it is desirable to have at least one tree in every garden, as the fruits after having done duty as an ornament may be used for decoration when gathered, as they are so highly coloured, or they may be put to a still better purpose by preserving them, for which they are valuable and worthy of cultivation. There are other varieties which are recommended, especially the John Downie, but here I find the Dartmouth the best.—R. PARKER, *Goodwood*.

MELON NOTES.

PROBABLY there was never a better season for the later crops of Melons. At all events, I have never had better or more finely-flavoured fruit, the continual sunshine having admitted of the freest ventilation up to only a week or so since. A plentiful supply of fresh air during the time the fruit is swelling hardens the principal leaves, and these remain on fresh and good until the last. The fruit from plants that retain their foliage is always of a much finer flavour than that not finished when the foliage begins to fall. It takes a little experience to know just when to diminish the water supply. If kept going too long, especially if the atmosphere is kept dry, the best and largest fruits are apt to crack at the point, this of course ruining their appearance and detracting from the quality. On the other hand, too sudden withdrawal of the moisture is bad for the foliage and stems and also the fruit. I never take a second crop from Melon plants, as when the fruit has well netted, this is considered rather more than the health of the plants. If feeding with any kind of liquid manure has been practised, it is then discontinued and water is given only in moderation, a longer time being allowed to elapse between the time of watering. The roots, however, are well soaked. If this is not done the roots nearest the surface get more than they need, while those lower down get none, and these lower roots are the strongest, of course. The consequence is an early collapse of the plant and a dead, mawkish flavour instead of the rich taste peculiar to a really well-grown Melon. A Melon to be good should be well ripened to the rind, and the depth of flesh depends, of course, upon the variety. There is no doubt many of our Melons at the present day are much too large. There is as much flesh in some of the little solid Melons that used to be grown as in the large hollow fruits now so much in vogue. I have tried several of these during the last few years, and in very few cases can they be described as good, or even fairly good. There is first a hard substance under the rind for about half an inch, then a little flesh—sometimes eatable, but often not—with a great cavity in the centre that one might put a fair-sized Melon into. The best variety I have grown this year in the green-fleshed class is Earl's Favourite. It is rather large, but the flesh ripens quite to the rind, and is thick and of excellent flavour. I am sending it to table now, and it is very much liked. The best scarlet-fleshed kind I have is Eureka, which has been described quite lately. H. R.

Apple Baumann's Red Reinette.—This may be strictly termed a heavy and continuous cropping Apple, and this recommendation, coupled with the fact that the fruits are highly coloured and of good size, constitutes it as being a good sort to grow for market. Young trees come early into bearing, and, when grown in the form of a spreading bush, it is surprising the quantity of fruit they are capable of carrying. I have no experience of it as a standard, but should imagine that it would succeed well as such, as its habit of growth would prevent the trees growing to too great a height, and the produce would not therefore be so liable to damage from high winds. I have seen excellent samples of this Apple at

different times this season, and also noticed a few trees of it well laden with fruit when looking round the Royal Horticultural Society's Gardens at Chiswick quite recently. It is not a first-rate Apple as regards flavour, but it is an excellent keeper, and remains in sound condition a considerable length of time in a cool store.—A. W.

The common Crab Apple in the shrubbery.—The garden varieties of Crab Apples, with their pretty red and yellow fruit, are admirably adapted for planting here and there in pleasure ground shrubberies, or even in groups by themselves, but the wild Crab is specially suited for park adornment. In one nobleman's park in Essex I have seen it towering to a great height and presenting a striking appearance in May, when the dense growth is laden with delicate blossom. When planted in close proximity to Oaks, these form a capital background. Later in the year, when the fruit just turning from a green to a pale yellow colour hangs on the branches, the tree is again attractive. Its rugged form of growth adds to its gracefulness.—N.

BLACKBERRY GROWING.

SOME twenty years ago the introduction of the large American Blackberries, such as Lawton, Wilson Junior and other sorts, gave a spurious spurt for a time to the culture of Blackberries in Britain. For a time at least a lively trade was done in American Blackberries at high prices. With few exceptions these new Blackberries proved failures. Either their size or other merits had been unduly puffed or our climate was unsuit-

Wooden seat, Warley Place. (See p. 356.)

able for them. Anyhow, the boom in foreign Brambles soon came to an end and was succeeded by a reaction in favour of our native species, *Rubus fruticosus*, in its many choice varieties. Of these perhaps the most profitable and ornamental is the cut-leaved Bramble (*Rubus laciniatus*). This is quite hardy, easily accessible to all, and yields a better return than any other known Bramble. Everyone familiar with Blackberry districts should also visit hedgerows and banks, carefully selecting the finest strains for their gardens and allotments so soon as practicable. For years I have been advocating Gooseberries as hedge plants for cottagers' gardens and allotments. In many districts and on many soils Brambles would make the better and quicker fence. These will grow and fruit on almost any site and in any soil with a minimum of culture. Nevertheless, it is equally true that few plants enjoy good soil or a full root larder more than Brambles. Give these 2 feet or a yard of soil and liberal treatment and note the admirable account Brambles will give in growth and fruitfulness. I know of no plants that will yield a better return from a given area under liberal culture than Blackberries, the average price in our large towns being 4d. or more per pound for fair samples. Brambles are also far more free from insect attacks than any other of our bush fruits. The berry-eating birds seldom severely attack ripe Brambles however large and luscious. In many districts Cherry culture has become impossible through the destructive voracity of the birds. Currants, Gooseberries, Raspberries, and Strawberries are also heavily thinned through birds

and other thieves, while Blackberries, however rich and luscious, seem safe. The Bramble has also a longer season than most of our berried fruits. This might also be extended at both ends by adding to the early and extending the late varieties. D. T. FISK.

FIGS—SINGLE STEMS VERSUS SUCKERS.

How frequently do we meet with Fig trees which are simply a mass of succulent, unfruitful suckers. Crops of fruit from such are small and the individual fruits rarely attain the size or ripeness so desirable in really good Figs. The reason for this state of things is not far to seek, when we know that all suckers rob the plant of its legitimate food, and, in the case of Figs, ultimately kill or render them utterly useless as a source of fruit supply. Once suckers are allowed free scope, the Fig tree immediately shows signs of weakness by producing short small wood with unusually small leaves and miserable apologies for fruit which seldom finishes properly. The tree is weakened as the suckers become more numerous. Fig culture after this fashion is unprofitable compared with the results invariably obtained where the essential root conditions are secured and a single stem connects the branches and roots. A striking example of successful Fig culture came under my notice some time ago in the gardens at Keele Hall, Staffordshire. The house was a lean-to with an area of 1050 square feet, the trellis at the same angle as the glass, and about 18 inches under it, and almost completely covered by one tree.

The one stem supported seven varieties. The original tree was a Brown Turkey, planted at the front of the house at about an equal distance from both ends. The trellis being 3 feet or 4 feet above the level of the border, a single stem had been run up to this height and then induced to branch. As other varieties were desired, they were grafted on these branches, and now Mr. Wallis can gather seven kinds from the same tree. What a contrast between the wood of this tree for fruitfulness and that of the ones manufactured out of suckers. At the axil of every leaf of Mr. Wallis's tree a fruit could be seen in some stage of development, according to its time of growth. From one house alone Mr. Wallis says he is very rarely without fruit from the end of May to the beginning of November. Of course, much can be done with one variety to keep up a supply of ripe fruit by stopping, but when several varieties are grown on one tree this object is considerably simplified. At places where glass-houses are not too plentiful and yet a continuous supply of excellent Figs is required, a leaf on

Fig culture might be taken out of Mr. Wallis's book. It will also be found a step in the right direction to have one large, well-grown plant instead of several small ones. Even by continually repressing growth and keeping it within too narrow limits, the plants are very apt to merge into trees of the sucker stamp, especially if well cared for with fertilisers at the roots. To be successful in the cultivation of Figs, whether one variety or several are grown on one tree, or whether the branches

Marble slab seat with Oak lattice cover. (See p. 356.)

have room to extend, or are severely restricted in growth, no root suckers should ever be allowed to develop. The growth of young shoots from lateral eyes on the branches is another thing: but even these, if required to fill a blank space of the trellis, should be kept well stopped in their earlier stages of growth.

J. RIDDELL.

Nectarine Downton Improved.—This Nectarine is well worthy of cultivation. I have never tried it out of doors, but in a second-early Peach house it did remarkably well, ripening about the middle of June, and only about a week later than Lord Napier, so that I was able to exhibit both sorts at one show. Downton grew at the less sunny end of the house, this being span-roofed. Had it been favoured with as much sun as Lord Napier, it would not have been a day behind it in ripening. As far as I know, Downton is not generally known as a good forcing Nectarine, but as I have proved it to be so, and it is

Stone seat, Paris. (See p. 356.)

of excellent flavour and a good bearer, others may be induced to give it a trial.—NORWICH.

The Japanese Wineberry.—I saw last autumn at Carrow House, Norwich, a fine lot of this Wineberry laden with its showy fruit. As noted at page 256, its principal use seems to be for preserving, and I was informed at Carrow that it was a favourite jam there. The plants have a very pretty effect, even in the kitchen garden, especially as at the date the fruit ripens other

small fruits are very scarce. "H. R." is correct in stating that a good rich soil is necessary, and I think the plants at Carrow had also the benefit of a good mulch of manure. Despite the fact that the fruit is somewhat acid, the plants had to be protected by netting from the attacks of birds.—C.

DESTROYERS.

BEES AND FRUIT.

In a recent issue Mr. Walker asked for a verdict of guilty or not guilty on an indictment which had been made against bees as fruit-eaters. I am not prepared to say that, as a rule, they are as persistently destructive as wasps, but in some seasons (presumably when honey material is scarce) I have found them most active amongst the Raspberries, also amongst Peaches and yellow Plums. I have found many bees lying hopelessly intoxicated in the skins they had helped to hollow out, and others greedily feasting upon the choicest fruit. Bees and wasps were, *arctus ambo*, alike robbers, but with a difference in favour of the wasps; these flew away when disturbed. The former, *more suo*, defended their booty with stings.—T. H. ARCHER-HIND, *Coombeshute, Devon.*

— Mr. Walker will, I fear, be greatly disappointed to hear from another source how very destructive the hive bee has been to soft fruits. Till this season I always believed bees to be entirely innocent of feeding on fruits. I find, however, that where they can get at Grapes they prove quite as destructive as wasps. When excluded from the vineries they became very busy among Plums and Blackberries, it being no uncommon thing to find a Plum with five or six bees feeding on it. A neighbour of mine who has kept bees for many years tells me that until this season he never knew them to eat fruit before, but is quite positive they are guilty of the offence this year. It would be interesting to learn the reason of their depredations, although, for one, I do not think it is due to lack of food in the hive.—E. PARSLow, *The Gardens, Brauford, Goudhurst, Kent.*

— I have managed bees in a small way for some years, but have not as yet been greedy enough to rob them of any more food than was advisable, whilst my ignorance does not reach the inability (after thirty-five years of garden life) to distinguish between a drone fly and a honey bee. Perhaps the assertion, "They do as much mischief as wasps in certain seasons," was a bit too sweeping taking fruit as a whole. One thing, however, is certain: that if bees take a fancy to any individual tree—whether Apricot, Plum, or Peach—they will clear it more quickly than wasps. They are more particular in their diet, selecting the richest and most sugary varieties. The season is now over, or I would have despatched a fruit showing mischief done, together with the bees caught in the act. E. BURRELL.

— Having been away from home, I had not the opportunity to read Mr. Burrell's note from which Mr. Walker quotes regarding bees attacking soft fruits. I can, however, quite bear out all that Mr. Burrell states in the paragraph quoted, as I suffer from their depredations to a greater or less extent every year. During the past season they have been more destructive than ever, and as regards Apricots, Peaches, and Plums, far more fruits were consumed and damaged by them than by wasps. The depredators are true honey bees, of which a good many are kept in cottage gardens near

at hand, and I have had plenty of opportunities of proving this, as I have seen them flying to and from the hives. At one time I kept several hives of bees in the garden, but did away with them on account of the damage they inflicted on soft fruits. I am aware that other species of bees in addition to flies work great havoc amongst the fruit, but honey bees in my own case were the greatest sinners during the season just past.—A. W.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 25.

AN extremely interesting and at the same time most instructive meeting was that of Tuesday last. A more thoroughly representative display could scarcely be brought together at this season of the year. The last of the outdoor summer or early autumn flowers, owing to the absence in a singular degree of early frosts, were still in evidence in Dahlias, of which two large groups were staged, whilst the earlier of the Chrysanthemums were in strong force. Of other flowering plants, Begonia Gloire de Lorraine was again shown in fine form, this being intermixed with other seasonable flowers and admirable decorative plants, Ferns, &c. An excellent assortment of well-grown half specimen Ferns came from another source, whilst a large group of finely grown decorative stove and greenhouse plants, including well-coloured Crotons, &c., was shown. A choice selection of variegated and other conifers, consisting of medium sized plants admirably adapted for planting, and a mixed collection of stove and greenhouse plants, which comprised autumn-flowering Heaths, Nerines and Begonias, were also noteworthy. Of Orchids there was again a good display, the newer and the choicer hybrids being in strong force. Of hybrid Lælio-Cattleyas there appears to be no cessation in production; many of the introductions of the past ten or fifteen years are now exercising their influence in a marked degree. The exhibits before the fruit and vegetable committee were both extensive and highly meritorious. A grand display of Pears and Apples was beyond anything else the feature of the meeting. Another admirable lot of fruit was somewhat lacking in colour, but otherwise of good quality. Well-finished Black Alicante Grapes were submitted, whilst from Harrow was sent *Vitis heterophylla humulifolia*. Some Celery, better than which no one could desire, being weighty, solid, well blanched and clean, was shown. The attendance was extremely good, the light being better than usual. Such an exhibition as that of Tuesday last, and at a season when a lack of exhibits might reasonably be expected, augurs well for the popularity of the Royal Horticultural Society, the only regrettable feature being that a building better suited to such gatherings and such as some of our continental neighbours possess cannot be had.

Orchid Committee.

A first-class certificate was awarded to—

CATTLEYA MARONI (*C. velutina* × *C. Dowiana aurea*).—This is one of the most distinct hybrids we have seen, the sepals and petals yellow, suffused with a bronzy shade of purple; the broad front lobe of the lip heavily crested on the margin, the ground colour yellow, suffused with rose-purple and heavily veined with crimson-purple; the side lobes rose at the apex, suffused with brown and lined with yellow towards the base. The plant carried a raceme of seven flowers. From M. Chas. Maron, 3, Rue de Montgeron, Brunoy, France.

Awards of merit were adjudged to the following:—

LÆLIA PUMILA COLEMANI.—A large and finely-shaped flower, the sepals and petals white, slightly tinted with rose. The large lip is white in the

centre, the whole of the remaining front lobe being covered with deep rose-purple. The side lobes are white, shading to bright yellow at the base. A plant carrying a raceme of two flowers came from Mr. J. Coleman, Catton Park, Reigate.

LÆLIA PERRINI LEICOPHILA.—This is a distinct and desirable variety, the sepals and petals almost white, having a suffusion of purple that gives them a peculiar blue tint. The front lobe of the lip is slate coloured, this replacing the crimson purple as seen in the typical forms. The side lobes are white, margined in front with the bluish tint of the front lobe. A plant carrying a three-flowered raceme came from the collection of Sir F. Wigan.

Messrs. J. Veitch and Sons sent a fine group, in the back row of which were numerous *Oncidiums* in variety, finely-flowered *Odontoglossum grande* and *O. Pescatorei*. Among the Cattleyas were good forms of *C. Bowringiana* and varieties of *C. labiata* and *C. aurea*. The hybrids consisted of *C. Mantini*, the sepals and petals deep rose, the lip rich velvety crimson, shading to yellow at the base, showing the intermediate characteristics of both parents in this portion of the flower, the lines of *C. Dowiana* being very prominent. *Lælio-Cattleya Nysa*, a grand form, a three-flowered raceme of *L. C. callistoglossa igneseens*, *Cypripedium conanthum superbum*, *C. Charlesworthi*, a grand variety of *C. Milo*, *C. Arthurianum* and the variety *C. A. pulchellum* were well represented. A strong plant of *C. insigne* *Sundera* was also included. Among *Miltonias* were *M. Morehana*, a pretty variety of *M. macrochila alba* and a small plant of *M. vexillaria Leopoldi* with three flowers. *Cologyne Veitchii* with two spikes of its pure white flowers was also shown. A silver Flora medal was awarded. Messrs. Stanley Mobbs and Ashton, Southgate, sent a nice group consisting principally of finely-flowered and good varieties of their well-known type of *Lælia pumila*. *Cattleya Warszewiczii* with two spikes, each with five flowers, and *C. Loddigesii* were also well represented. *C. labiata* *Lewisii* is a distinct and beautiful variety, with pure white sepals and petals, the whole of the centre of the lip rich crimson-purple with a broad margin of white, the side lobes white, shading to yellow at the base. Several forms of *Odontoglossum crispum*, *Oncidiums* and *Cypripediums* in variety were also included (silver Banksian medal). Messrs. F. Sander and Co. sent several varieties of *Cattleya labiata*, a finely-flowered plant of *C. Harrisonii*, a light form with two spikes of *Cymbidium Traceyanum* labelled *C. grandiflorum*, *Habenaria militaris*, and *H. earnea*. Messrs. Hugh Low and Co. sent a fine variety of *Cypripedium Evoor*, showing the yellow and spotted characters of both parents.

Sir F. Wigan, Clare Lawn, East Sheen, was awarded a silver Flora medal for a choice group, in the back row of which was a finely-flowered plant of *Cypripedium elegans* with eight spikes of flower. *Cymbidium Winnianum*, with a fine spike of its pretty white and brown flowers, was also shown. Among the *Cattleya labiata* was a good variety of *C. l. alba* with three flowers. Several fine forms of *C. Dowiana*, a distinct variety of *C. Eldorado*, *Lælio-Cattleya* The Hon. Mrs. Astor (*C. Gaskelliana* × *L. xanthina*), good varieties of *Cypripedium Arthurianum*, a fine form of the yellow-ground section of *C. Godefroyae leucochilum*, and good forms of *Lælia pumila* were also included. Mr. Greenwood, Highfield, Haslingden, sent the original plant of *Lælio-Cattleya H. Greenwoodii*, very similar in many respects to the variety described in our report of the last meeting. Mr. J. Douglas sent *Lælia Bressii* (*L. purpurata* × *L. harpophylla*) with seven of its creamy white and rose flowers. Mr. W. Cobb sent a plant with undeveloped flowers of *Cypripedium insigne* *Sundera* and another yellow form with indications of spotting on the dorsal sepal. Mr. W. A. Gillett, Fair Oak Lodge, Bishopstoke, sent two good forms of *Cattleya Warszewiczii* and a pretty *Dendrobium Phalenopsis* with delicate rose tinted flowers. Mr. F. W. Moore, Glasnevin, was awarded a botanical certificate for *Angraecum*

Germanium, the sepals and petals creamy white suffused with brown, the lip pure white. Two cut flowers were shown. The Rev. Goodliff, Worthing, sent *Cypripedium Boxalli* × *C. Io grande*, but the flowers were not equal to those of either of the parents.

Floral Committee.

The following received first-class certificates:—

DRACENA VICTORIA.—A Brazilian species that partakes of the character of *D. Lindenii*. The plant is of good habit, the gracefully recurved leaves having bands of yellow, varying from pale to golden. From Mr. Wm. Bull, King's Road, Chelsea.

PTYCHOSPERMA SANDERIANA.—An elegant and pleasing Palm of somewhat spreading habit, and bearing in some cases radical breaks, as in *Areca lutescens*. From Messrs. Sander and Co., St. Albans.

Awards of merit were given to the following:—

CHRYSANTHEMUM MAJOR MATHEW.—A distinct and well-proportioned incurved flower of a pleasing shade of lilac. From Mr. W. J. Godfrey, Exmouth.

CHRYSANTHEMUM BARONNE DE VEILLARD.—This is an acquisition to the incurved section. The flowers are bronze, slightly touched with gold. From Mr. Robert Owen, Maidenhead, and Mr. W. J. Godfrey.

CHRYSANTHEMUM HETTIE MITCHELL.—A useful addition to the semi-early section, the plants bearing quantities of moderate-sized flowers on freely branched stems. The colour as shown is golden yellow, tinted orange. Height 2½ feet. From Mr. W. J. Godfrey, Exmouth.

CHRYSANTHEMUM NELLIE BROWN.—This is a bronze sport from the well-known *Ryecroft Glory*. Splendid plants were shown by Messrs. Cannell and Sons and Mr. Wells, Redhill.

CHRYSANTHEMUM SOLEIL D'OCTOBRE (Japanese incurved).—This Japanese incurved is of a charming shade of soft yellow, and should prove an acquisition. From Mr. Leopold de Rothschild, Acton (gardener, Mr. Jas. Hudson), and Mr. H. J. Jones, Lewisham.

CHRYSANTHEMUM GOLDEN QUEEN OF EARLIES.—An exact counterpart of the white form in shape and size, the flowers of a pleasing shade of yellow. From Mr. H. J. Jones, Lewisham.

ROSE SUNRISE (Tea).—This in its colouring, or more strictly combined colouring, is unique, the outer petals reddish carmine, shading to delicate fawn and pale salmon within, the open blossoms of a pleasing yellow. The chief value of the flower is in the warmer tints that are so abundantly apparent as the flowers open, and these coupled with the bronzy foliage are charming. The flowers, too, are produced in great abundance, the buds being exceptionally well formed. From Mr. G. W. Piper, The Nurseries, Uckfield, Sussex.

A large group of fine-foliaged plants, mostly of large size, was set up by Mr. A. Howe, gardener to Sir Henry Tate, Park Hill, Streatham Common. Some well-grown examples of *Dracenas*, *Crotons*, *Palms* in variety, splendid pieces of *Arundinaria*, *Cycas*, *Asparagus Sprengeri*, *Microlepia hirta cristata*, and *Anthuriums* were included in the group, the *Dracenas* being 5 feet high, well coloured, and bearing foliage to the pots. The whole was margined with small grasses and *Crotons* (silver-gilt Banksian medal). Messrs. J. Hill and Son, Lower Edmonton, sent a choice assortment of greenhouse Ferns, many of the plants of good size and well grown. Some of the finest examples were *Gymnogramma calomelanos*, a handsome and distinct spreading species, slightly powdered; *Asplenium crenatum*, *Leucostegia immersa*, with fronds of a pleasing pale yellow-green; *Davallia Mooreana*, *Lastrea lepida*, *Pteris tremula Smithiana*, and *Adiantum scutum roseum* (silver-gilt Banksian medal). From Bagshot Messrs. J. Waterer and Sons brought an assortment of variegated conifers that proved of interest to many, most of the examples being compact and well formed. The whole of the plants were wonderfully fresh and of clean

growth, and, in the majority, compact also. A silver-gilt Flora medal was awarded. Mr. H. B. May, Edmonton, filled one side of a long table in the centre of the hall with a mixed arrangement of beautiful and useful plants, including capital flowering examples of *Begonia Gloire de Lorraine*, very pleasing and well grown, many *Palms*, Ferns in variety, *Bouvardia jasminoides*, *B. alba odorata*, a lovely kind with delicate flesh-tinted flowers; *B. Maiden's Blush*, always a popular kind; *Carnation Mrs. Leopold de Rothschild*, *Asplenium Mayi*, small *Crotons*, *Erica caffra*, *E. hyemalis*, and a couple of groups of *Chrysanthemum Mutual Friend*, a pure white kind. Most of the plants were set in small groups or colonies, and in this way gave effect to the whole (silver Flora medal). Mr. John R. Box, Croydon, had a fine lot of *Begonia* flowers taken from the open. These were of excellent quality for so late a date. Messrs. J. Cheal and Son, Crawley, had an assortment of coloured foliage and flowering shrubs, among which the *Scarlet Oak* (*Quercus coccinea*) was the most important plant. The two species of *Winter Cherry*, *Physalis Alkekengi*, and the more modern Japanese form, *P. Franchetti*, were also in this group. Mr. S. Mortimer, Farnham, Surrey, had a splendid display of *Dahlias*, of which ten boxes were show and fancy kinds, together with a large assortment of *Cactus* kinds, the flowers beautifully fresh and clean, and of quite a representative character (silver Flora medal). Mr. T. S. Ware, Tottenham, had a very large bank of *Dahlias*, the flowers as good as any shown in the season, such kinds as *Fantasy*, *Startish*, *Mrs. C. Turner*, *Matchless*, *Sylvia*, *Mrs. F. Fell*, *Blanche Keith*, *Ensign*, *Leonora*, and *Robert Cannell* being set out in bold groups, with occasional small plants of *Pampas Grass* to relieve the mass of colour. There was also a good assortment of singles and pompons in good condition. These, with a collection of early *Chrysanthemums* of poor quality, completed a most extensive arrangement (silver Banksian medal). Mr. A. Kingsmill, Harrow Weald, sent a beautiful lot of *Vitis heterophylla humulifolia*, covered freely with blue and purple berries. Messrs. R. and G. Cuthbert, Southgate, had plants of the new decorative *Chrysanthemum Mrs. Wingfield*, a variety of dwarf habit, with flowers of a pleasing pink hue. Mr. W. Wells, Earlswood, Redhill, had a fine group of *Chrysanthemums*, representative of all sections of the flower. *Crimson Pride* was very fine. This, it should be stated, is the kind that last year bore the name of *Pride of the Market*, the alteration having been made because another kind had already had the same name bestowed upon it. *Mme. Liger Ligneau*, a fine yellow; *Ambroise Thomas*, crimson-brown; *Nellie Brown*, bronze sport from *Ryecroft Glory*; *Queen of Earlies*; *Mytchet White* and *Mytchet Yellow*, both excellent; *Bouquet Feu*, terra-cotta; *Ivy Stark*; *Roi des Precoces*; and *Jules Mary*, crimson, were very fine. A fine lot of well-grown Japanese kinds, together with some seedlings of promise, were included in this group (silver Flora medal). Mr. C. A. Pearson, Frensham Place, Farnham (gardener, Mr. J. Prewett), had several boards of very good blooms, mostly Japanese, among which *Mons. Chenon de Leche*, orange-amber and chestnut; *G. W. Childs*, *Royal Sovereign*, *Globe d'Or*, and *G. C. Schwabe* were good (silver Banksian medal). Another lot of flowers came from Exmouth, from Mr. Godfrey. *Le Grand Dragon*, *President Bevan*, *Autumn Glory*, soft lilac, *Beauty of Adelaide*, another pleasing lilac shade, *Rayonnante*, and *Werther*, crimson, were all fine blooms. *Emily Grunerwald*, a yellow, was very pleasing, though not quite full in the centre. Mr. Robert Owen, Maidenhead, was also the exhibitor of a nice lot of blooms, though many of these were seedlings and under no distinctive name. *Mrs. Winkley Smith*, *Lord Boston*, *Soleil d'Octobre*, *Miss Godsmark* (light bronzy brown, very pleasing), and *Miss Singleton* (white incurved) were good. A Japanese kind, *Miss Mary Leschelles*, is a white sport from *Reine d'Angleterre*, and a promising flower. This was shown

by Mr. H. P. Leschelles, Windlesham, Surrey (Mr. W. L. Farmer, gardener). A nice lot of blooms came from Messrs. H. Cannell and Sons. These were backed up with flowering sprays of *Polygonum molle*, the flowers abundant and forming a distinct foil to the *Chrysanthemums*; *M. de Blanc*, *Soleil d'Octobre*, *Lady Byron*, *Lady Ridgway* (gold-bronze), and *Mme. J. Henry* were all good. Another exhibit of these autumn flowers came from Mr. H. J. Jones, Lewisham. *President Nonin*, *Mrs. A. Cross*, *Mr. A. Barratt*, bronze sport from *C. Harman-Payne*, and *Julia Scaramanga* (a fine gold) were excellent. From Highgate, Messrs. W. Cutbush and Sons brought a mixed group of *Heaths*, *Skimmias*, *Palms*, *Pernettyas*, *Begonia Gloire de Lorraine*, and a capital lot of *Nerine Fothergilli major* in flower. One of the most striking plants in the hall on this occasion was a splendid piece of *Anthurium crystallinum illustre* with leaves 18 inches across and 24 inches long, of a deep green and olive-green shade, irregularly marked with large patches of cream and creamy yellow. This noble example came from Mr. R. Gulzow, Melbourne Nurseries, Bexley Heath. Other plants of *A. crystallinum* were sent for comparison. From Chelsea, Mr. W. Bull brought *Mimosa argentea*, a kind showing white near the midrib; *Ficus radicans variegata*, very pretty and as free in growth as the type; *Maranta picta* (*Calathea*) with deep olive-green leaves; and *Ceropegia Woodii*, a curious climbing plant, the foliage freely marbled with white on a pale green ground. Flower-trusses of the common *Horse Chestnut* were sent by Mr. Boyce, Marsh St. Farm, Dartford, to show the result of the season. This, however, is by no means uncommon in ordinary years, and one tree in the neighbourhood of Twickenham appears somewhat frequently in flower during the autumn months.

Fruit Committee.

The collection of Apples and Pears from Mr. George Woodward, Barham Court Gardens, was a notable one. Here was exhibited the cream of the fruit shown at the Crystal Palace, the Apples being remarkable for their size, colour, and finish. *Peasgood's Nonsuch*, *Mère de Ménage*, the *Queen*, *Lord Derby*, *Gascoigne's Scarlet*, *Emperor Alexander*, *Sandringham*, *Royal Russet*, *Warner's King*, and *Lane's Prince Albert* were remarkable. Of the dessert kinds, *Blenheim Orange* was a grand dish, as was *Mabbott's Pearmain*. *Worcester Pearmain* was the best dish we have seen this season. *Burnack Beauty*, *Wealthy*, *Ribston*, *Allington Pippin* and *Dutch Mignonne* were splendid. The best Pears were *Doyenné de Merroda*, *Brockworth Park*, *Beurré Alex. Lucas*, *Beurré Diel*, *Fondante de Thirriot*, *Nouveau Poiteau*, *Gen. Todtleben*, *Marie Benoist*, *Emile d'Heyst*, *Gansel's Bergamot*, and *Nouvelle Fulvie*. This excellent collection was awarded the Hogg memorial medal. Messrs. J. Cheal and Sons, Crawley, staged one hundred dishes of Apples and Pears. Though not equal to the Kent samples, the fruits were grandly coloured. *Bismarck* was very fine, as were *Bramley's Seedling*, *Royal Jubilee*, *Alexander*, *Annie Elizabeth*, and *Monstrous Incomparable*. *Blenheim* was excellent, as were *Ecklinville*, *Golden Noble*, *Grenadier*, *Frogmore Prolific*, *Loddington*, *Lord Derby*, and *Peasgood's Nonsuch*. In the dessert section, *Mother*, *Nancy*, *Dutch Mignonne*, *Ribston*, *Cox's Orange*, *Atalanta*, *Beauty of Stoke*, and *Worcester Pearmain* were excellent. The best Pears were *Conseiller de la Cour*, *Beurré Hardy*, *Gloire Morceau*, and *Pitmaston Duchess* (silver Knightian medal). Messrs. Laing and Sons, Forest Hill, also staged one hundred dishes of fruit, *Bramley's Seedling*, *Bedfordshire Foundling*, *Bess Pool*, *Annie Elizabeth*, *Ecklinville*, *New Hawthornden*, *Hollandbury*, *Magnum Bonum*, *Mère de Ménage*, *Newton Wonder*, *Northern Greening*, and *Sandringham* being the best. The dessert varieties included all the well-known kinds (silver Banksian medal). Mr. J. Prewett, Frensham Gardens, Farnham, Surrey, had a nice lot of Pears and Apples, *Wellington*,

Lady Henniker, Lord Derby, Peasgood's Non-such, Blenheim Orange, Cox's Orange, and Ribston Pippin being good. The Pears were very good, Thompson's, Eyewood, Beurré Superfin, Louise Bonne of Jersey, Magnate, and Emile d'Heyst being the best (silver Banksian medal). Mr. Howe, Streatham, sent three good bunches of Black Alicante Grapes, and Mr. Miller, Coombe Abbey Gardens, showed *Passiflora edulis*, but the fruits were nearly green and quite hard. Mr. F. C. Bunce, New Galloway, sent ten sorts of Apples. Mr. Miller, Ruxley Lodge Gardens, sent half a dozen of Wm. Tillery Melon, a variety certificated twenty years ago. The fruits sent were much rounder than the original. Mr. Herrin, Dropmore Gardens, sent a very beautiful lot of Coe's Golden Drop and Brahy's Green Gage Plums. Mr. Vert, Audley End Gardens, Saffron Walden, had an interesting exhibit in fruits of *Gymnocladus canadensis*. Mr. Crump, Madresfield Gardens, Worcester, sent a seedling Apple not unlike Adams' Pearmain; also a dish of Maltster Apple, given a very high character for quality. Seedling Apples in great variety, but of no special merit, came from Mr. J. Fielder, Salisbury Green, Southampton. From Syon House Gardens, Brentford, Mr. Wythes sent the Melon which received an award at the last meeting, also an interesting exhibit in the shape of a distinct variety of Banana. This was a dwarf Cavendish, the plant having been fruited under twelve months. From Messrs. Veitch, Ltd., Chelsea, came a very nice lot of St. Joseph Strawberry, runners from this year's plants, fruiting freely in 3 inch pots.

Mr. Beckett, Aldenham House Gardens, Elstree, Herts, staged a very beautiful collection of Celery, solid, large, and clean. In many cases the difference is very slight. Few kinds were superior to Standard-bearer and Major Clarke's. Early Rose, Superb White, and Leicester Red were also good (silver Banksian medal). Some eight kinds of Beetroot were brought up from Chiswick. Mr. Wythes also sent a new seedling Tomato, very nice fruits of medium size, perfect in shape, and of excellent quality. This was a cross between Duke of York and Conference, and the committee desired it to be sent to Chiswick for trial.

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday last an interesting meeting of the floral committee of this society was held at the Royal Aquarium, Westminster, when the chair was taken by Mr. Harman Payne. The exhibits, mostly of a high average quality, came principally from Messrs. W. Seward, H. J. Jones, W. Wells, H. Weeks, W. J. Godfrey, and T. Spink.

First-class certificates were awarded to the undermentioned novelties, viz.:—

CHRYSANTHEMUM MRS. W. SEWARD.—A large finely-built Japanese, and, like many of Mr. Seward's seedlings, very rich in colour. It is deep in build, the florets flat and of good substance, and very regularly arranged. The colour is deep rosy cerise with a reverse of gold, and the florets are tipped and edged gold. Mr. W. Seward.

CHRYSANTHEMUM MARKET WHITE.—Decorative Japanese; a pretty little flower, colour pure white, tinted sulphur in the centre. From Mr. W. Wells.

CHRYSANTHEMUM JULES MARY.—Another decorative Japanese; florets narrow, stiff, and neatly disposed; colour bright crimson, reverse golden. From Mr. W. Wells.

CHRYSANTHEMUM MRS. W. CURSHAM.—In this the florets are broad and deeply grooved, twisted and intermingling at the tips, the ground colour white, shaded pale lilac-mauve. From Mr. H. Weeks.

CHRYSANTHEMUM MRS. WINGFIELD.—A very pretty decorative Japanese flower, somewhat resembling the Christines in form; colour deep bright pink. From Mr. W. J. Empson.

CHRYSANTHEMUM ADA OWEN.—A very nice-looking, regularly-built incurved, close and com-

pact flower, florets broad and stiff, the blooms of good size; colour pure white. From Mr. R. Owen.

CHRYSANTHEMUM LADY PHILLIPS.—An incurved Japanese, florets very broad; colour pale mauve, with a reverse of silvery pink. From Mr. R. Owen.

CHRYSANTHEMUM MRS. GEORGE HILL.—A pretty little decorative Japanese with white drooping florets, centre shaded yellow, very free. From Mr. H. J. Jones.

CHRYSANTHEMUM PRESIDENT BEVAN.—Japanese incurved, a big, massive flower, florets grooved and pointed; colour deep golden-yellow, shaded bronze. From Mr. W. Wells.

CHRYSANTHEMUM MAJOR MATTHEW.—An incurved, with rather narrow florets. It is a globular, well-built, medium-sized flower; rich rosy pink. Shown by Mr. W. J. Godfrey.

Specially noteworthy were the following: Miss Mary Leschelles, a pure white sport of great merit from Reine d'Angleterre; Miss Godsmark, a golden-bronze Japanese, which the committee wished to see again, as they also did Thomas Singleton. Mr. M. Russell, a fine golden-chestnut coloured incurved, was also asked to be sent up again. Mme. Couvat de Terrail, pale flesh-coloured Japanese, and Le Grand Dragon, a big yellow Japanese, were the objects of a similar request. Autumn Glory, a pink-coloured Japanese with a shiny reverse, was commended. Ellen Shrimpton, a very bright and pretty deep rosy cerise Japanese kind, and Mytchet Beauty, a golden-orange decorative variety of the Japanese type, the committee wished to see again.

Forthcoming foreign Chrysanthemum shows.—There are many indications of the way in which the popularity of the Chrysanthemum is spreading, but few perhaps so marked as the rapid growth of Chrysanthemum exhibitions abroad. Without taking into account American fixtures, which are almost as numerous as our own, it is interesting to note that in Egypt, Algeria, Germany, France, Belgium, and Italy Chrysanthemum shows will be held. A list of these will be found in our show fixtures.

NOTES OF THE WEEK.

Weather in the west of Scotland.—We are having summer weather here—55° in the shade—and all our Roses are doing beautifully. I have been cutting basketfuls of fine blooms every day.—RICHARD NIVEN, *Airlie, Ayr, N.B.*

Chrysanthemum Emily Silsbury.—Among the early-flowering white-flowered kinds, the one named is likely to become a permanent favourite. The blossoms are of good size and of a pure and snowy whiteness. The variety, too, is not of very tall growth, a by no means unimportant point.

Rhododendron Souv. de H. Mangles.—This may be counted among the most distinct of the javanic hybrids, and possessing also flowers of considerable merit and good colour. The predominant colour is a deep salmon, shaded orange, the two colours blended in the most beautiful manner.

Pæony foliage in autumn.—We are sending you a bunch of foliage cut in the open field from our herbaceous Pæonies to call attention to the beauty of colouring in the leaves. Pæonies with us are almost as beautiful in October as in May and June, and the foliage is in request for decoration.—KELWAY & SON.

Tibouchina (Lasiandra) macrantha is a very old and indeed a very popular greenhouse climber that will be freely recognised by its older name as above. Few plants are more deserving of general culture than this, for in the violet-coloured saucer-shaped flowers the plant is quite unique. It is a strikingly beautiful plant that is easily grown by anyone having a greenhouse.

Lobelia Crimson Gem is undoubtedly the finest of the dark crimson-maroon shades yet seen in these flowers. In this respect the variety is probably unique, though we incline to the opinion that in the garden the value of these very dark kinds is infinitely less than would be the case were they of a brighter shade. Nor should we forget the value of these things

in autumn decoration, when the more heavy and intense shades are even less needed than earlier in the year.

Solanum Seafortianum.—This very pretty and useful species from the West Indies is of climbing habit and flowers for many weeks in succession. The habit, too, is by no means without its pleasing features, and is graceful and elegant, though seen to best advantage when the drooping clusters of mauve-coloured blossoms adorn the plant for so long a period during the summer, and often the autumn months also. Like many species, it is not difficult to cultivate and may be grown in large pots or planted out.

Zizania aquatica (the Canadian Rice).—This rare plant was noted recently flowering freely in the aquatic tank at the end of the herbaceous ground at Kew. The plant, which reaches to nearly 7 feet high and produces a bronzy red inflorescence, is of erect, graceful habit, the long lance-shaped leaves gracefully recurving and impressing one by their breadth. Near by in the same tank was the Japanese form, *Z. latifolia*, which is decidedly more drooping and of a much more spreading habit of growth. Singularly enough, this species, though of good size, has not yet flowered, though growing under the same conditions as the Canadian form.

Crocus speciosus Aitchisoni.—Dr. Aitchison's variety of the fine *Crocus speciosus* comes into bloom with me a little later than the type where grown in a similar position. The flowers are rather larger than those of the type, but are less showy in their colouring. It is, however, useful to have some variety among the flowers of this fine *Crocus*. Dr. Aitchison's variety comes from Afghanistan, and has been in cultivation only a short time.—S. ARNOTT.

Colchicum hololophum.—Under this name I have a rather pretty Meadow Saffron, which here comes into bloom a little later than the majority of the other single-flowered *Colchicums*. In colouring it is a little more rosy than some of its congeners. According to the best authorities, *C. hololophum* is a synonym of *C. montanum*. It is possible that the plant here may be one of the forms of that species, difficult to distinguish without comparison of living plants. It is growing here through the foliage of one of the Pinks, and its flowers look well coming up among the glaucous leaves of the *Dianthus*.—S. ARNOTT.

Crocus hadriaticus var. chrysobelonicus.—The name of this pretty variety of *Crocus hadriaticus* is not likely to recommend it to many, and Dean Herbert might with advantage have given it a simpler and more pleasing name. It refers to the hill of Chrysobeloni, in Santa Maura, where it was found. The figure in Mr. George Maw's monograph hardly does justice to this pretty, if not showy, member of a favourite genus. The flowers are small and white with a yellow base, instead of the blue of the typical *C. hadriaticus*. The anthers are orange-yellow and the stigmata scarlet. My date for its flowering here this year is October 21, from established corms.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Aster alpinus and slugs.—The remarks relative to the fondness of slugs for *Aster alpinus* in the interesting article by "E. J." accompanying the coloured plate in *THE GARDEN* of October 22 make me ask if any growers of this pleasing little *Aster* have observed that these pests care less for the white variety than for the others. I have noticed this for several years, and while I find much difficulty in keeping the coloured forms, have little trouble with the white. I place their taste for the coloured forms thus: Purple, first; rose, second; white, third. I should not like to say that this is invariable, as it is seldom one has an opportunity of comparing one's experience in this with that of others, but this is what happens here.—S. ARNOTT, *Carsethorn, by Dumfries, N.B.*

Verbenas in October.—I forward a few flowers gathered this morning. The flowers of *Salvia splendens* are from cuttings taken in the spring. The plants have been in flower for about six or seven weeks, and the blossoms have been freely cut for indoor use. The *Verbenas* are from seed sown in February. They have been in bloom since the end of June, and the bed is still gay

with them, as they have flowered profusely, except during the last two weeks of the great heat in September. The scarlets are now not so vivid as a short time back.—P. SHEENY, *Montebello, Totteridge*.

* * A beautiful gathering of flowers, the Verbenas large in truss and individual flower. Raising from seed is certainly the best way of growing Verbenas.—ED.

Tufted Fancies flowering late.—The welcome rainfall and consequent prevalence of moister conditions have quite altered the appearance of these plants. For a month or two they presented a poor appearance, and instead of there being a free display of blossoms, many collections have suffered considerably. A number of plants which were cut back early in August last have flowered freely within the last fortnight, and although my garden is very exposed, the display at the time of writing is good. *Isa Fergusson*, blue-black, shaded lavender, has been in splendid condition. *Pembroke*, a good rayless yellow, and many seedlings from this sort, have flowered profusely. *Aurora*, a splendid purple-violet and lavender fancy flower; *Nellie*, cream-white, rayless, and a large number of seedlings raised in the spring are still flowering.—D. B. C.

Chrysanthemums in the open border.—Varieties which during a normal season are seen at their best throughout September are now making a brave display, being probably two to three weeks later than usual. As a consequence the welcome display of colour in the outdoor garden is opportune, as the Michaelmas Daisies and other autumn flowers are mostly over. Mention should be made of *Mlle. Guindéau*, a free-flowering pink sort, tinted and suffused white, and possessing a nice bushy, spreading habit; and *President Lefevre*, a pretty and delicate blush flower. A striking flower is *Bronze Dwarf*, its rich bronzy crimson blossoms, with golden reverse, being much admired. This variety has a splendid constitution, and the same may be said of *Ambroise Thomas*, which bears freely blooms of a beautiful rich reddish crimson.—C. A. H.

Dracæna Eeckhauti.—Among the green-leaved section of this family, the above, a kind that received an award of merit recently at the Royal Horticultural show, is worthy of note. It differs from several well-known forms, such as *D. terminalis*, *D. congesta*, and others of similar habit, in the shorter leaves being more thickly situated on the stem, in being much more recurved, and in their exceptional dark green colour. It frequently happens also that these green-leaved forms are fairly hardy, enduring the cool, dry temperature of the sitting-room for many weeks with impunity. These are the points that render them of the greatest value as pot plants, and the above, should it prove equal to the others in these respects, will make a useful addition to available room plants. It is of a much more graceful habit than is usually seen in these plants.

Begonia metallica.—This free-flowering species is too little seen in gardens, probably also too little known. Indeed, when directing the attention of a gardener of middle age to some excellent examples in flower recently, he candidly informed me he did not know the plant, and was looking at it for the first time. Doubtless there are others who would with equal surprise note the fine examples of this species now to be seen at Kew, where for weeks past the plants have been a feature in one of the greenhouses. It is not only the size of the plants that attracts, it is equally the remarkable profusion of blossoms the plants carry and the handsome display such things make where they have received the necessary cultural attention. The flowers are white, and freely covered on the outside with pinkish hairs that produce a very pretty effect. Another kind with somewhat smaller foliage and rather similar flowers is *B. echinosepala*, possessing equal freedom of flowering. These are of especial value during the late summer and early autumn months, and are useful in large conserva-

tories or the like. With a little care both kinds continue flowering till the end of the year.

Chrysanthemum Queen of the Earlies.—On page 319 attention is called to an exhibit of mine at the recent exhibition of the National Chrysanthemum Society. The writer says that "the blooms were notable examples of this fine early white, that is, as far as the heads were concerned, for the stems, which were cut of an extraordinary length, were quite leafless—a possible result of the dreaded rust." Queen of the Earlies is almost rust-proof, but as the blooms had to be cut on the Saturday, the stems were stripped previous to being packed for the 200 miles journey, as by no other means could the blooms be prevented from wilting or the florets from drooping. For years past bare stalks have been exhibited by all the principal trade growers at the National Chrysanthemum Society's meetings, and if the writer will turn to the society's schedule either for this year or last, he will find that in certain classes it is insisted that the long-stemmed blooms be denuded of all foliage, the object being to retain the freshness of the blooms.—W. J. GODFREY, *Exmouth*.

PUBLIC GARDENS.

Addition to Epping Forest.—Mr. Edward N. Buxton's offer of twenty-eight acres, to be added to Epping Forest, was yesterday gratefully accepted by the Court of Common Council. The addition is at Yardly Hill, Sewardstone.

Pleasure ground for Newcastle.—We learn that Mr. Ralph Sneyd, of Keele Hall, has presented plots of land for pleasure and recreation grounds to the borough of Newcastle-under-Lyme and the neighbouring villages of Silverdale and Knutton. The Newcastle portion includes the site of the old castle of the feudal period.

Hampstead Heath extension.—At a recent meeting of the Paddington Vestry, the Rev. Walter Abbott presiding, it was resolved that the sum of £500 be contributed towards the fund for the purchase of Golder's Hill Estate, provided the estate is handed over to the London County Council for the public use as an open space. The General Purposes Committee of the Middlesex County Council have recommended a grant to be made to the Golder's Hill Acquisition Committee of £500.

The Metropolitan Public Gardens Association.—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding, it was stated that the association had finished the laying out of Guy's Hospital ground, Bermondsey, and had begun the laying out of Albion Square, Dalston. It was agreed to begin work at the Paragon and Portland Place, New Kent Road, and at Plaistow Churchyard as soon as the transfer of these grounds to the local authorities had been completed. It was decided to provide trees for planting in Hoxton Market, to make a grant of seats for the ground known as the Clapton Pond and Paddocks, and to provide some gymnastic apparatus for a gymnasium in Whitechapel. It was mentioned in regard to two important schemes in which the association had been taking an active part—namely, the Queen's Wood, Highgate, and the Golder's Hill estate, Hampstead—that the former had been opened to the public since the date of the last meeting, and that the committee, under the chairmanship of Sir Henry Harben, had received great encouragement in the vigorous efforts made to secure funds for the acquisition of the latter, so that only about £1000 was now required to complete the purchase money, which it was hoped the Middlesex County Council and the Paddington Vestry would provide between them. It was announced that granite drinking fountains had been recently erected in Shoreditch and Pentonville Churchyards, Brooke's Market, Barnsbury Square, and East Ham Park by means of special donations made to the association, and that one-half of the additional

land for the Postmen's Park, E.C., had now been purchased and was being laid out, about £3000 being still required to complete the purchase of the remainder of the site.

The weather in West Herts.—Most of the days during the past week were somewhat cold, while the nights, on the other hand, were mostly warm. At the present time the ground is about 2° warmer than is seasonable, both at 2 feet and 1 foot deep. Rain fell on five days to the aggregate depth of nearly 1½ inches, or more than in any week for over a twelvemonth. During the past few days three gallons of rainwater have come through the heavy soil percolation gauge, and three and a half gallons through the light soil gauge. Both gauges are a yard square and the soil in them 2½ feet deep. The record of bright sunshine during the week was very poor, and on three days no sunshine at all was recorded. By 9 a.m. on the 18th the barometer had fallen to 28.80 inches, which is the lowest reading recorded here in October since 1886.—E. M., *Berkhamsted, Oct. 18*.

—A warm week. On three days the shade temperature rose above 60°, and on no night did the exposed thermometer fall lower than 37°. During the night preceding the 21st the lowest reading indicated by the same thermometer was only 48°, which is a high minimum temperature for so late in the month. At the present time the soil at both 1 foot and 2 feet deep is about 3° warmer than is seasonable. During the ten days ending the 23rd rain fell to the total depth of 2 inches, which is the largest amount deposited here in any consecutive ten days since December last. There was a good record of sunshine on the 23rd and 24th, but during the remainder of the week the sun shone brightly for altogether only about an hour.—E. M., *Berkhamsted*.

Odentoglossum citroæmum.—This plant, referred to in our issue of October 22, p. 332, is grown in the way there stated in Mr. Mann's garden at Ravenswood, Bexley.

The Alpine Starwort plate.—The Alpine Aster (*A. alpinus* superbus and vars., pink and white) was drawn in Mr. Perry's nursery at Winchmore Hill, and not at Kew, as stated by error in the letterpress.

Earl's Court Exhibition.—We have been asked to state that the International Jury of the Earl's Court Exhibition, Ltd., have awarded Messrs. John Laing and Sons, of Forest Hill, the diploma and a gold medal for their display of flowering plants, &c., during the past summer.

Poor lawns.—My tennis lawns are nearly half covered with the dark brown parasite commonly known as witch's butter. Will any of your readers kindly oblige by telling me of an effectual remedy? The subsoil is chalk, covered with the usual vegetable mould, varying in depth from 2 inches to 2 feet.—JAMES STEVENS.

"The English Flower Garden."—The sixth edition is out of print, and the work is being rapidly reprinted, and will be issued in November. Henceforward it is proposed to bind a certain number in two vols.—I. Design, and II. Plants—in sage-green morocco, for library use or presentation. Published at Ligu net.

BOOKS RECEIVED.

"The Farmer and the Birds." By E. Carrington. With preface by Canon Tristram. G. Bell and Sons, Covent Garden.

"Culture of Flowers from Seeds and Bulbs." By E. Kemp Toogood, Southampton. Toogood and Sons, Southampton.

"Practical Rose-growing." By John Harkness, Bedale, Yorks.

"Manual of the Grasses of New S. Wales" (with illustrations). By J. H. Maiden, Government Botanist and Director Botanic Gardens, Sydney. W. A. Guelick, Sydney.

Names of plants.—*R. Niven*.—1, Moon Daisy (*Pyrethrum uliginosum*); 2, the Plantain is only a malformation.—*Fritz*.—*Lycium europæum*.—*H. Tibble*.—1, Aster horizontalis; 2, A. levis; 3, A. multilorus.—*W. Sangwin*.—*Kniphofia grandis*.

Name of fruit.—*J. Ridden*.—Pear *Beurré d'Ananlis*.

ORCHARD AND FRUIT GARDEN.

SYRINGING PEACH TREES.

IN THE GARDEN, October 22 (p. 317), in the article on "Early Peach Houses," the following appears: "I think many failures in early Peach forcing are due to the thoughtless practice of syringing the trees in the afternoon on cold, wet days," &c. When I took charge of the gardens here in the autumn of 1887, it was decided to pull down the then existing old Peach houses and replace them with new ones, retaining some of the Peach trees, which to all appearance had been planted many years. The range was divided into three compartments and all heated separately. I had the old houses cleared away, built walls, &c., reduced to secure the full amount of front light in new range, then the houses built over the old trees, the work being carried out during December, 1887. By the time the work was completed the buds were swelling, consequently the trees were allowed to start away quietly and no syringing was done. The trees having been somewhat roughly treated during the building, and to all appearance not in a flourishing state, not much attention was bestowed upon them, there being so much else claiming attention. Nevertheless, all the old trees retained flowered fairly well, set freely, and eventually ripened a nice crop of very useful fruit in 1888. One of the compartments was entirely filled with young trees, which were planted in March, 1888, without being cut back in any way. During the growing season the strongest growths had the points taken off in order to better equalise the growth. The following year, when starting, the old and young trees alike were syringed carefully twice a day until the flowers began to open. In each case the buds dropped very much, especially on Stirling Castle, Royal George, and Noblesse, so much so that very little thinning of fruit was required. In 1889 and 1890 the same treatment was continued, with the same disap-

pointing results, namely, buds dropping. After having tried a good many, if not all, of the so-called remedies to prevent bud-dropping, I determined to try what the result would be in one house by discontinuing the syringing. To my surprise the trees not syringed dropped very few buds, set well, necessitating a good deal of thinning of fruit, and ripened their fruit well.

The following year all the Peach houses were thoroughly cleaned as soon as the trees shed their leaves, the borders dressed and watered, the houses started in due course, and strict orders given to the young man in charge that no syringing was to be done upon any account. The result was that with the single exception of one tree of Downton Nectarine every tree flowered splendidly, and set quite three times as many fruits as were required. From then until the present time the same practice has been carried out, and each year scarcely any buds have dropped; the fruit set freely, and required to be thinned freely. I crop heavily each season, the first Peaches being ripe as a rule about May 20. The young trees planted in March, 1888, grew away freely, and were allowed to fill their allotted space, never having been cut back beyond stopping any very strong shoot, as already stated. The old trees have all been cleared out and replaced with young ones. My opinion is that the most fruitful source of Peaches dropping their buds is the result of syringing the trees when the trees are started and the buds swelling. I would advise anyone who may be troubled with his Peach trees casting their buds to try for one season the result of non-syringing, and I am confident he will very soon adopt the principle. All the borders and paths in the house are damped every morning and afternoon from the time the house is shut up for starting until the flowers are open, and even then I do not allow anything like dryness in the house while the fruit is setting. As soon as the fruit is set the trees are slightly syringed at first for a few days; after that the garden engine is

used freely morning and afternoon, every part of the interior of the house being well moistened. Should red spider or aphid appear, a syringing with quassia extract very soon settles either.

Under the above culture, labour is reduced and the results all that I could desire. I grow the following sorts: Nectarines Pine-apple, Humboldt, Downton, and Lord Napier; Peaches Royal George, Stirling Castle, Noblesse (the best-flavoured Peach yet grown, in my opinion), Crimson Galande (an enormous cropper year after year), and Princess of Wales, which I think the best late Peach in cultivation, being a certain cropper, fruit large and of excellent quality. None of the trees have ever been root-pruned, heavy cropping rendering that operation quite unnecessary. By judiciously applying Thomson's Vine manure, enormous crops of fine Peaches can be obtained yearly and the trees maintained in vigorous health.

DAVID KEMP.

Stoke Park Gardens, Slough.

Cellini Pippin Apple on a wall.—Some of the very finest Cellini Pippins both in size and colour I have seen were from a tree growing on a wall having a south-easterly aspect at Barnby Manor, Newark. The crop was a heavy one. The soil at Barnby is shallow, and fruit trees on walls have to be mulched and freely watered in dry summers. On warm soils, where canker is not likely to affect it, this Apple does admirably on espaliers, the fruit growing to a large size and colouring beautifully where fully exposed to the sun. Fruits so grown are good enough for dessert if eaten when in their prime. Unfortunately, earwigs are very partial to this Apple, being easily pierced by them, wasps then following in their train. I have also always had to net the trees on espaliers against tomits and black-birds.—J. C.

Grape Muscat Hamburg.—What a pity it is this magnificent Grape is so seldom seen in really first-rate condition. I do not see mention of a single exhibit of it at the late Palace show. A few years ago some fine examples were grown

and exhibited by Mr. Goodacre, of Elvaston. The late Mr. Fowler used to grow it well at Castle Kennedy up to 5 lbs. and 6 lbs. a bunch. Some of the best bunches I have ever seen were growing in a span-roofed house of mixed Vines near Birmingham some years ago. The Vine was inarched on to the Black Alicante, and the bunches, besides being of good size and well finished, had not a shanked berry in them. It seems to like a strong loam, and I know those at Castle Kennedy were grown in such a medium. I have an idea that varieties such as Muscat of Alexandria and Mrs. Pince are to a great extent prevented from shanking and shrivelling by having the roots in a heavy rather than a light loam, especially when the borders are inside, as such a medium retains moisture better and is of a more regular and even temperature. When well grown there are few Grapes that can surpass Muscat Hamburgh either for appearance or flavour.—NORWICH.

APPLES IN PAPER BAGS.

It is now some years since a very simple and ingenious method was contrived by the Apple growers of Montreuil for heightening the natural colour of Apples, enhancing their appearance and value at the same time. This consists in putting the Apples into paper bags, and after a given time removing the bags. I should say, however, that very probably when the first attempt was made, colour was not the principal object. The principal object then was the protection of the fruit from the eggs of butterflies engendering Apple and Pear worms (*Carpocapsa pomonella*). In any case the process is doubly efficacious, since both objects are attained. Trade also has benefited by it, as the bags are specially made for this purpose. The result obtained is in fact wonderful; the fruits so treated resemble Apples made of sugar or wax carefully coloured. Calville Blanc and Reinette Blanche du Canada, the two market Apples *par excellence*, have an incomparable whiteness and delicacy of skin without any lessening of their other qualities. Although bags are specially made for the purpose, the waste paper merchants also make bags as good and as impervious to rain and wind and possibly less expensive.

When the Apples are the size of a large nut is the time to put the bags on. After squaring the bag in the manner of grocers, a slit is made in one of the sides about 00'6m. to 00'8m. long. The Apple is then inserted, the stalk being run through the slit up to the end. The two edges of the slit are then brought together so that this side opening is made hermetically fast round the fruit stalk, then the proper opening of the bag is fastened in its turn by crushing the edges together and tying with matting or thin string. If, as one might be tempted to do, we should insert the Apple through the regular opening of the bag, it would be impossible to enclose the fruit without also including the leaves that surrounded it, and further, the ligature being tied round the fruit stalk would greatly impede the circulation of the sap unless it were tied loosely, in which case the object of having a bag would be lost, as the insects would enter in spite of it, and would find in it a sure protection from insecticides. The introduction of the Apple through the side opening obviates this objection.

During growth the Apple is thus sheltered against the inclemency of the weather and against insects. Only towards the month of September should the fruit be exposed to the light, and this should be done gradually, as otherwise the sun's rays striking upon the delicate skin would inevitably discolour the fruit. The right way, therefore, is to first of all cut off the bottom of the bag, and, later on, choose

some dull or rainy day for removing the bag altogether. The Apple being exposed to the air and the light, both agents combine to give it the fine carmine tint which is so much admired and never seen so clearly except in fruit that has been covered up in the way described. Producers take advantage of this method to print designs in a natural way on the skin of the fruit whilst still uncoloured on leaving the bag—a name, initials, &c.—and succeed in the happiest way. Last year, it will be remembered, the fruiterers of Paris exhibited in their shops some superb Apples with the arms of Russia printed upon them to perfection. This result is very easily obtained in the following way: The design is first cut out in paper, no detail being omitted. The paper known as "Joseph" is the best, as its transparency permits of tracing, and from its flexibility it is easily adaptable to the sinuosities of the fruit, which are sometimes very pronounced. The design is stuck to the upper surface of the Apple immediately the latter is withdrawn from the bag, and after a few days, the sun's rays having produced their effect, the fruit begins to colour, but only around the paper, under which the skin retains its normal tones. The time for gathering having come, the paper is removed, and the design appears perfectly imprinted on the fruit. Another way is before removing the bag to cut out the design on the side of the bag exposed to the sun. When the light enters through the aperture it colours the design on the fruit in red. In this case the bag should be left on the fruit until the time of gathering. This latter way I have employed myself for several years past to imprint certain initials.—CLAUDE TREBIGNAUD, in *Le Jardin*.

Peach Princess of Wales.—In the note by "H." (p. 255) he states that this fine Peach has little to recommend it except its handsome appearance. "H." has, perhaps, never tried it in pots. Grown in this way in a cool house and removed to a heated house to finish, with plenty of air day and night, and gathered as soon as it parts freely from the tree, the flavour is greatly improved. As a September Peach under glass it is very hard to beat, treated as I have advised. Gladstone is a pale coloured fruit of delicious flavour, and a fortnight later than Bellegarde.—M. T.

Raspberries failing to grow.—Of comparatively easy culture though the Raspberry, failures often have to be recorded in the case of newly-planted canes. This is not to be wondered at when the canes are despatched from the nursery in a rough-and-ready manner without the slightest protection to the roots. These, which have sometimes suffered from drought before being lifted from the ground, are, owing to exposure during transit, so dried up as to be of little or no value. I have as a safeguard against failure arranged with the nurseryman to envelop the roots in some well-moistened material. This prevents shrivelling, and, if well soaked for a time previous to planting, their vitality is preserved. It is just the same with Roses.—C.

Peach tree failing to fruit.—I have in a house a Peach tree which bore no fruit this year. I was thinking of removing it outside, under a north wall, and covering it overhead with zinc. Please say if this would improve it, or what would you recommend?—E. Q.

* * * You do not say what position your Peach tree occupies in the house, the variety, and, what is equally important, the age of the tree. You would certainly do wrong to put it on a north wall, which is the worst position possible. An east wall is not good, the best, of course, being a south or south-west wall. Had you planted your tree outside from the start it would have been better. You do not say if your house was heated; if so, to plant the tree, if of any size, on such an

aspect or even under the best possible conditions would be lost time, as it would certainly fail. On the other hand, if you reversed the conditions and planted a tree from an open wall in the house there would be a certainty of success. Peaches to do well need the best culture. They cannot get this on a north wall, as they cannot ripen the new wood made. You say your tree bore no fruit; why not adopt other means to make it fruit? If your tree is growing too strong, we would advise lifting. Now is a good time to do the work, carefully forking out all small roots and digging at least a yard from the tree. Probably you may find some large roots. These will need to be clean cut or shortened back, replanting a little higher and giving the roots some old mortar rubble, burnt soil, or anything that will induce a fibrous root growth. Replant as firmly as possible and do not give any manures, which can be given in the form of a top-dressing when the tree begins to fruit.—ED.

STRAWBERRIES AND THE DROUGHT.

ALTHOUGH a spell of hot weather is beneficial while the fruit is ripening, at no other season is protracted drought desirable in Strawberry culture. On light, porous land especially, many plantations will have suffered severely by the absence of rain since the crop was gathered. Of course, where a deep, rich tilth was prepared previous to planting, or in naturally cold, late districts with a retentive soil, the season has proved all that could be desired. In most gardens, however, in the south and midland counties, where only ordinary cultivation has been followed with probably a scarcity of water at command or the labour to apply it, there is a danger of the plants having been considerably weakened, and next season's crops will naturally suffer in consequence. But this is not the only disadvantage to be anticipated. In what condition are the plants this season which it is intended to force later on?

Never, perhaps, was greater difficulty experienced in securing suitable early runners or more attention needed afterwards to induce them to root freely into the small pots in which they were layered. The parent plants for the most part were in a parched condition at the roots, and, being spread over a wide area, it was not always convenient or possible to supply copious waterings. Moreover, red spider revels under such conditions, the foliage being smothered with this minute insect, giving it quite a burnt appearance, and, what is worse, preventing the fruit attaining either its full size or quality. The young leaves on the runners soon fell a prey also to its attacks. Then, again, the amount of time required to water the small pots twice a day could not be afforded in all gardens, with the result that when the season arrived for severing the young stock from the parent plants, it would be found they were of stunted growth and unsatisfactory in the extreme. Even when they were arranged at the foot of a north wall, where it was less trouble to keep them moist, they did not out-grow the trying ordeal they had experienced, and at the time of placing them into the fruiting pots they were about half the size they ought to have been. Those who have a good water supply and can flood their plantations with a hose as required know little of the difficulty less fortunate growers have to contend with in preparing the desired number of plants for forcing during a season like the past. It is the latter who are grateful for any hints that will assist them out of their difficulties, and perhaps the following method for raising next year's stock of plants may prove of assistance to those who have not already adopted it. The most common practice of raising Strawberry

plants for forcing is to layer the runners into small pots, sever them from the parent plants when sufficiently rooted, potting them up afterwards into the fruiting pots. The labour entailed from first to last is great, and can ill be afforded in some gardens during the height of summer; therefore, with limited assistance a less laborious method which is more likely to turn out successfully should be resorted to.

SECURING THE RUNNERS.

The much-needed rains have fallen recently in most parts, and, in common with all vegetation, Strawberry plants have greatly benefited thereby. The work of clearing the plantations of runners, weeds, &c., and affording a mulching of manure is work usually carried out about now. Instead of destroying all the runners, look the beds over carefully and secure all the strongest. Having cut the bine and nipped off the second lot of runners, raise each young plant carefully with a handfork, not altogether with a view of securing a ball of earth attached, but to prevent the roots being damaged. Having secured as many as are required, transplant them into nursery beds, allowing from 6 inches to 9 inches space between each plant according to their size and strength. Should the soil be dry, one good watering will settle the ground round the roots and induce growth at once, and so they will become established before winter. No more attention will be required until spring, when the hoe should be run between the plants to break the surface and check weeds. As the season advances the strongest may show a flower-truss, which should not be allowed to develop, or the plants would be weakened. The removal of runners, too, is necessary directly they form, so that all the strength goes to the plant. By these simple means strong, healthy plants will be secured for placing into the fruiting pots without the time and labour of using a number of small ones and the subsequent attention of keeping the small quantity of soil they contain in a suitably moist condition for the runners to root into. Moreover, plants raised in nursery beds are easily watered should it be necessary to do so, and, not being near old or exhausted plants, they do not become infested with red spider.

POTTING UP THE STOCK.

July is about the best month to pot up the plants. This allows of the pots becoming crowded with roots and the crowns well matured before winter sets in. Care, however, is necessary in lifting the roots, as at that season suitable weather, such as dull, showery days, are uncommon. It is a good plan to cut round each plant, say a fortnight previous to lifting, with a small, sharp spade to sever the longest roots, and to save this proving a check, a thorough soaking should be given afterwards if the foliage flags during the bright days, another watering being afforded a few hours before the plants are lifted if the ground be dry to ensure a good ball to each. Only a limited number should be lifted at a time and potted up at once. A cool, shady place should be selected on which to arrange the plants and the foliage kept syringed to prevent flagging, which would only be noticed for a few days. When new roots have formed and the plants are growing freely, a more exposed position should be selected to give strength to the new leaves, when the after-treatment is the same as that usually followed.

PLANTS FOR FORMING NEW BEDS.

Runners are always strong and plentiful in the autumn; therefore a good store should

always be selected and planted in the reserve garden for future requirements. It is too late then to transplant them direct to their permanent quarters and expect them to yield a crop the following season, but by careful handling they will make splendid plants for putting out, say, at the end of June, when a suitable piece of ground is cleared of some early crop. The great thing is to allow each young plant plenty of room to develop, say quite 6 inches each way, and not to crowd them together in shallow trenches, which is commonly termed "laying them in by the heels." Moderately rich soil, made rather firm by treading, and an open position prove most suitable, as when placed on deeply dug loose ground they grow too rank and the roots strike too deeply instead of forming a mass of fibres near the collar of the plants, and so enable them to be lifted with a nice ball of earth attached. A good reserve of plants always being available with a minimum of trouble or expense, they may be treated as annuals if desired, and no one would complain of the weight of fruit secured from a given space, as under this treatment planting may be done much closer than is the general method. I would strongly recommend the practice where early outside crops are required and valuable south and other warm borders have to be given up to them. I do not claim anything original in managing plants in this way—indeed, it is a practice followed many years ago—and though we are apt to ridicule much of our forefathers' handiwork as "being an old fashion," many of their methods might still be followed more closely with advantage, especially in trusting more to the open borders for raising young stocks of plants and less to the pot-and-house system.

ESTABLISHED BEDS.

As stated previously, these in most places have suffered severely, the main leaves having been practically scorched up weeks ago from the effects of the dryness of the ground and the prevalence of red spider. Much may be done, however, to restore vitality and render the plants capable of carrying good crops if taken in hand at once. The roots for the most part will be active again now the state of the ground is more favourable and capable of taking up any nourishment afforded, especially in the shape of liquid manure. Some of the worst of the foliage and all weeds and rubbish should be cleared from the beds and the space between the plants carefully hoed, not dug. If liquid manure can then be used freely, the roots will feed greedily and so be able to form good strong crowns this autumn; moreover, the ammonia will greatly assist to cleanse the plants of red spider. I would certainly prefer treating the plants in this way at once than let them remain as they are until winter, when the frozen state of the ground suggests the too common practice being followed, viz., wheeling on a mass of rotten manure and spreading on the surface. Feed the roots now and expose the soil between the plants to a few sharp frosts, which will act as a purifier and destroy slugs and other pests which prove troublesome in the cultivation of this popular fruit.

Goodwood.

RICHARD PARKER.

NOTES AND QUESTIONS.—FRUIT.

Pear Williams' Bon Chretien on the Quince stock.—I quite agree with "W. H." (p. 256) as regards this Pear on the Quince. I planted some cordons on the Quince against a south wall two years ago. This season I have gathered some splendid fruits from them, these being of large size and first-rate flavour, and much superior to Clapp's Favourite, which seems

rather shy in bearing and lacks the fine constitution of its parent.—M. T.

Late Nectarines.—An omission occurs in my note on late Nectarines (p. 308). After Spenser, Newton Seedling should have been mentioned. This is a particularly fine, mottled, richly-flavoured variety and a good setter. In a Peach house facing east at Hillside, Newark, this Nectarine succeeds well. This and Spenser may be planted on open walls in warm localities, but Victoria must have protection to ensure regular crops of well-ripened fruit.—J. C., Norwich.

Apple Allington Pippin.—Having had several opportunities lately of seeing this variety in a fruiting state, I am glad that I added it to my collection. In each instance the trees were bearing freely, the fruits being clean, of fair size, and of just the right size for the dessert. This Apple has, I think, a great future before it, while it is a more free grower than Cox's Orange, which it greatly resembles in appearance. It was also shown at the recent Crystal Palace show in good form.—A. W.

Peach Bellegarde.—I quite agree with what "J. C. T." (p. 308) says of this variety. I find it a regular bearer, the fruit of fine flavour, and almost black on the exposed side when fully ripe. I have a tree which was planted outside in 1872. It has had no protection except a fishing net hung in front of it, and every year since it has borne a crop of fruit. This season the first was gathered on August 20 and the last on September 25. Several fruits weighed 7½ ozs. each.—H. G., Lane Villa, Lancaster.

NOTES OF THE WEEK.

Osmanthus ilicifolius argenteo-variegatus.—A capital example of this well-marked shrub was noted at the Drill Hall the other day in Mr. Waterer's fine group of conifers. The specimen in question was about 2½ feet high, as much through, and very prettily marked with a silver variegation.

Chrysanthemum Nellie Brown.—This pretty bronzy sport from Ryecroft Glory was strongly in evidence at the recent meeting of the Royal Horticultural Society, plants and flowers in abundance coming from various sources. It is, however, an open question if there are not better kinds possessing the same tone of colour.

Aster turbinellus and the pretty single Chrysanthemum Miss Rose constitute a pair of most serviceable subjects for the greenhouse. Both are grown in some quantity at Kew for the decoration of the greenhouse, and arranged alternately in the Camellia section, which is always as cool as possible, remain a long time in good condition.

Gladioli, late-blooming kinds.—Since the introduction of M. Lemoine's spotted kinds the season of bloom has been considerably lengthened. I have a great liking for these late-blooming kinds, as they are so useful to cut from. At the present time (Oct. 24) I can cut nice spikes of a pale pink kind named Sultana. Calypso is another good late kind. These are most profuse bloomers and grow very freely.—DORSET.

Vitis heterophylla humulifolia.—A number of fruiting branches of this pretty Vine were shown by Mr. A. Kingsmill, Harrow Weald, at the recent fortnightly Drill Hall meeting. The mature stage of the fruits is an amethystine shade of blue, which gives a very pretty effect by the numerous clusters that form along the branches of the current season's growth. The plant is worthy of greater general attention from gardeners.

Salvia azurea grandiflora.—The value of this for late flowering in the open can scarcely be fully recognised, or it would be more freely employed. For some time past, while the garden has been gay with masses of early Chrysanthemums and Dahlias, there has been quite a scarcity of exceptional bits of colour, and at such times the value of so fine a plant in bloom is quickly apparent. The variety will endure several degrees of frost with impunity.

Zephyranthes candida.—Just now in the rock garden, or indeed in any position where it can be accommodated, this is one of the most charming of bulbous plants now in flower. The blossoms are exquisite in their cupped form and very pure, and when fully expanded in the warmer parts of the day it is a pretty flower indeed. The commoner form, Z. Atamaseo, is also in flower, and makes one of the prettiest possible displays at this season to be found among dwarf subjects.

Euryops Athanasie.—The golden Marguerite-like flower-heads of this plant should render it a very

striking subject for the greenhouse, provided the species blooms with the same profusion as the Marguerite. This, however, is scarcely possible judging by the plants now in bloom at Kew, and which are producing flower-heads somewhat sparingly. The growth generally and the foliage give a very distinct aspect to the plant, quite unlike that of anything else bearing similar flowers.

Salvia splendens grandiflora.—When frost and pelting rains and cold nights have caused the beds in gardens generally to be cleared of their usual summer occupants, it is gratifying to note this striking plant flowering on as freely and as persistently as could only be expected in the cooler days of summer. It is therefore of more than ordinary value, and a mass of it in full bloom at Chiswick in the gardens of the Royal Horticultural Society, on the 29th ult., and which has been flowering for weeks in succession, is a sight worth remembering.

Oxalis hirta.—Just now in the mixed collection of Cape flowering subjects in the No. 7 range at Kew several pretty kinds of Oxalis are in bloom. The above has large handsome blossoms of a mauve-lilac shade, and the variety *O. h. rosea* has flowers of a rich carmine-rose shade. *O. crenulata* is almost identical in colour, and is certainly a very showy, as it is also a free-flowering, species. As a marginal plant in the cool greenhouse or conservatory these pretty Oxalises are suitable.

Vanilla planifolia.—Stretching along the entire back wall of one of the Banana houses in the gardens at Syon House is what may be termed a plantation of Vanilla, which has not only grown with exceptional freedom and vigour, but is now yielding its fruits in abundance. The clusters are composed of from ten to eighteen individual fruits, a fact alone which speaks for itself. Many of the fruits are nearly 9 inches long. The crop as a whole is a valuable one, and is regarded by Mr. Wythes as the finest he has ever had.

Chrysanthemum Australie.—This is probably among the largest ever raised. Essentially an exhibition kind, it yet possesses a wondrous vigour of growth, and in the great length of the peduncle, which holds the massive blooms erect, it is possibly unique. A probable drawback is its great height, the plants reaching fully 7 feet, the enormous blooms therefore not readily seen in the ordinary way. The colour is rose-amaranth, with silvery reverse. This variety is grown in quantity by Mr. Wythes at Syon House.

October Dahlias.—Possibly nothing could more fully demonstrate the exceptional mildness of the season than the wonderful array of Dahlias of all sections to be seen at the recent meeting in the Drill Hall. The flowers were as fresh and clean as is usual in the heyday of their beauty. Nor was it a blossom or two of each kind, the sorts generally being represented by two or three dozen flowers each—a remarkable display for the 25th of October. The effect of the blossoms was good amid the usual gloom of the ever-gloomy Drill Hall.

Browallia speciosa major is among the most beautiful of blue-flowered plants at this time and a plant specially suited to the warm greenhouse. It is, moreover, one of those subjects that does not lend itself to cutting so much as some things, and for this reason the plants are attractive over a long season. The continued demand for plants only suitable for supplying cut flowers in quantity has been the means of ousting not a few of the prettier subjects that are not specially useful in this way. At the same time this *Browallia* is particularly pleasing and in many a greenhouse rare.

Lateness of outdoor Chrysanthemums.—Many of the so-called summer-flowering Chrysanthemums appear much later this year than was the case, for example, in 1897; indeed, many of the kinds marked as flowering in the first three weeks of September had not opened a solitary bloom when September was past and gone. Whether this is general is difficult to say, but in many gardens around London it is the case. In my own case I attribute it to the dry state of the soil for so many weeks both at planting-time and

later, thus preventing any progress at a most important season.—GROWER.

Michaelmas Daisies.—The splendid group of these flowers brought recently to the Drill Hall by the Messrs. Veitch and Sons showed the value of these things for lifting for pot work. The whole of the plants were handsome bushes, and, for a year phenomenally dry and intensely hot, well grown and flowered. The evidences of lifting, too, were very meagre, showing, when carefully done, how little the plants suffer in consequence. This with due preparation will leave the plants but little worse for the operation, and where whole sheaves of blossoms are needed, these Starworts mingle remarkably well with Chrysanthemums and other flowers.

Dimorphanthus mandschuricus in fruit.—I send a specimen of *Dimorphanthus mandschuricus* in fruit. I planted it twenty-two years ago, and never remember it to have been so grand as this autumn in flower, and it is scarcely less beautiful in fruit, though all the richly coloured foliage has disappeared. The specimen herewith has suffered from wind and rain in the past fortnight, and some white fluffy remains of infertile flowers have only just fallen; those among the fruits had a pretty effect. In light land and a sunny place this dwarf tree is always attractive, especially in late summer and autumn.—J. Wood, Woodville, Kirkstall.

Bouvardia odorata alba.—Among the long-tubed section of Bouvardias few are of greater value than this. Indeed, as a pot plant it would be preferred by many amateurs by reason of the somewhat shorter tube of the flower, and which is less likely to break or double over as compared with the varieties having longer tubes. Besides the fragrance, which is very decided in this kind, there is a tint of flesh in the unexpanded buds and also on the reverse side of the divisions of the corolla. The latter is in size about intermediate between that of *B. jasminiflora* and the equally well-known *corymbiflora*, the flowers freely borne on compact, bushy-habited plants.

Chrysanthemum nipponicum.—This is a remarkable species if only from the point of view of its wide-spreading habit of growth. The species is of Japanese origin, growing about 2½ feet high, freely branched and furnished with large and almost fleshy leaves, deeply notched at the margin. Grown from seed and planted in good ground the plant would arrest attention by its foliage and growth generally. This year, however, the long drought has kept its growth as well as flowering in check. Indeed, scarcely any flowers were apparent till the rain set in a few weeks since. The great almost succulent leaves, moreover, do not impress one as to the absolute hardness of the plant, which is not likely to be much of a gain.

Funkia subcordata grandiflora.—Your advice to "W. W." as to the growth and requirements of Plantain Lilies is excellent, but I fear will be of no avail to flower *Funkia subcordata grandiflora* unless your correspondent's garden is in a very warm part of England. I have had this Plantain Lily more than twenty years, and have quite failed to make it bloom, except in the greenhouse; there never seems enough sun-heat for it out of doors. Five other varieties of *Funkia* flower well here every year. Sieboldi is the best of them; its blue green leaves, which turn in autumn to a lovely shade of yellow, its compact lilac and white blossoms, very freely produced, and its robust growth make it one of the finest of hardy perennials.—J. H. W. Thomas, Belmont, Co. Carlow.

Delphinium sulphureum (Zalil).—It is to be hoped that the illustration of the well-grown group of this yellow-flowered Larkspur in THE GARDEN of October 29 will induce others to at least make the acquaintance of so distinct a plant. It is really a very pleasing Larkspur, whose principal drawback is its being practically an annual or biennial species. This has been very well pointed out by "E. J." in the article accompanying the illustration. My experience with

this Larkspur corroborates the practical information given by "E. J." in other respects. It will be seen from the illustration that there is some difference in the spikes. This I observed in my own garden, some being much looser and less compact than the others. From seed there was also a slight variation in colouring. With me this Larkspur did not ripen seeds nor did it flower the second year. It sent up a few weakly shoots after blooming, but these dwindled away. Those desirous of growing this sulphur-yellow Larkspur could not do better than follow "E. J.'s" advice as to its culture.—S. ARNOTT.

Androsace lanuginosa.—This lovely free-flowering alpine is almost as gay as it was in the end of the month of May, and any alpine that has such an uninterrupted period of flowering should certainly be regarded with general favour. Throughout the whole of the past six months this pretty plant has produced quantities of its pleasing coloured heads of bloom. Nor is it now an accidental or solitary head of bloom, as on the last day of October exactly two dozen flower-trusses were in full beauty on one little patch and a similar lot on another hard by. In the genus as a whole there are many exquisite gems that give cultivators great trouble, not to say anxiety, and even with the best care many losses are recorded. The above trailing species, however, is not of this number and may be grown with perfect success by any amateur in deep sandy loam and leaf-mould. A deep root-run is very helpful for such things, and a mulching of small stones will retain a considerable amount of moisture to the benefit of the plants in dry seasons.

Crocus lævigatus.—While the late autumn and winter Croci suffer much from the heavy rains of the time, and are consequently only a short time in full beauty, they are most attractive in the garden. Among these late-flowering species the pretty little *C. lævigatus* deserves a place in our gardens. It is a variable species in its colouring, especially in the marking of the outer segments. In his monograph (plate 49) Mr. George Maw gives a series of flowers illustrating this variation. Some of these varieties I have not met with, but any would be worth taking care of. The inside of the flowers varies from white to lilac, and the outside is sometimes self-coloured buff, or suffused or feathered with purple. I have a very pretty form here deeply suffused with rich purple and having the interior of the flowers almost white. The fact that the leaves come before the flowers is to me an additional recommendation in favour of this little Crocus. It is of dwarf habit—a considerable point in favour of a flower which comes when stormy weather is prevalent. According to Mr. Maw, *C. lævigatus* comes from the Morea, the mountains about Athens, and the Cyclades.—S. ARNOTT.

Early-flowering Chrysanthemums.—The early and semi-early kinds of Chrysanthemums to many people seem hardly worth the trouble of growing; yet in the garden in the autumn they deserve a prominent position, being in most cases of a dwarf and spreading habit of growth, free and continuous flowering, their season extending over quite two months. The out door garden may with a wise selection of varieties be made gay with them during September and October, and into November in seasons such as the present. They also stand frost well, the blooms not being in the least injured after a cold snap. Plant them out in May in good, rich soil, giving plenty of room, and sheaves of bloom will be forthcoming in the dull autumn months. Messrs. Dobbie and Co., of Rothesay, send us a beautiful collection of these from the open ground, these including all the well-known varieties, some of the kinds, though introduced many years ago, still ranking among the best. Of those sent, a few of the best Japanese are Coral Queen, Mme. Marie Masse, Lady Fitzwygram, Mytchett White, Mons. Gustave Grunerwald, Roi des Precoques, Notaire Groz, and Orange Child. Of the pompons we note Mrs. Cullingford, Fred Pele, Jacintha, Martinmas, Strathmeath, Nanum and Silver-smith.

THE DOWAGER LADY HOWARD DE WALDEN'S GARDEN AT ST. JAMES'S, WEST MALVERN.

ONE does not expect to find a noteworthy garden on the Malvern Hills. To those who know this grand mass of igneous rock, rising abruptly from the fertile plains around and dominating them like a crowned monarch covered, as it is, with close turf and Gorse broken every here and there by projections of the red-purple stone, while, except on the lowest fringe of it, absolutely treeless—the thought of a garden, a very storehouse of horticultural treasures, would be about the last to suggest itself. But the present decade has seen a new departure in this respect, for, somewhere about the beginning of it, the Dowager Lady Howard de Walden, the possessor of a picturesque strip of the western slope of the hills, having built a stately

by the tiny streams of pure water with which the hills abound, furnishes somewhere about sixteen acres for garden culture. While sheltered from the north and east winds, it lies open to the west and south-west, and affords a rich variety of views extending southwards over the hills of the Forest of Dean, and westwards over the Black Mountains and other hills of Brecknockshire and Radnorshire, which are (and will be more and more as the growth of the trees creates a succession of vistas) of quite exceptional beauty. The mansion on the garden side is flanked by stone terraces, adorned with handsome balustrades and covered cloistral walks, crowning effectively the rich vegetation beneath. Immediately below the terraces on the western front is a sloping lawn, of which, at the time of my first visit, the prominent ornament was a large bed, some 20 feet in diameter, filled with plants of the Crimson Rambler Rose, trained on wires

work of more or less prolonged experiment to adjust the contents of the several beds and borders in respect to colour, height, and time of flowering, and this is evidently an object which the skilful head gardener, Mr. Fielder, is setting himself, so far as it has not been already attained. In one respect he is helped in this by the uniform moisture which seems to permeate the soil just beneath the surface, for an evidence of which we might see a plant like *Polygala Chamæbuxus* growing freely and pushing up strong shoots on rockwork with a southern aspect and in a scorching summer like the present, not to mention that plants, such as *Arenaria balearica*, and even *Spigelia marilandica*, did not suffer greatly from pretty much the same position. Beneath one of the upper terraces a noble line of *Romneya Coulteri* was flowering splendidly, covered with mature blossom and with much promise for weeks to come.

A long narrow border of *Tigridias* of more than one variety edged one of the green grass walks, which are a feature of the garden and are but little browned by the heat wave of 1898. The two species of *Zauschneria*, *californica* and *latifolia*, were used largely for late summer decoration, as also were *Pentstemon barbatus Torreyi* and *Montbretia crocosmiciflora*. With regard to the last of these, I ought to notice that a considerable space under one of the terraces was devoted to its newer varieties. Some few those sent out as *Eldorado*, *Feu d'Artifice*, *Flore jaune*, and *aurea*—were noticeable for distinctness of colour, but of the majority it must be owned that they were scarcely distinguishable from the normal hybrid. But probably hardly anything in the garden in the latter half of August would strike a visitor more than the wealth of magnificent *Gladioli*, mostly *Lemoine's* hybrids, which was displayed.

An enumeration of the more beautiful of these, where all were beautiful, would be difficult, but I took note of a few which were perhaps the most perfect in form and colour, or at any rate pleased me most. These were *Professeur le Monnier*, *Masque de Fer*, *General Sausier*, *Le Grand Carnot*, *General Carrobert*, *Fulgurante* and *Deuil de Carnot*. In no garden, either private or professional, have I seen so striking and, I fear I must add, so costly a collection. Another feature of the garden perhaps quite as remarkable—though with regard to this I speak with but very limited knowledge—was the collection of hardy Water Lilies (*Nymphæas*) of many colours, growing in large stone-edged basins, the water of which was supplied by the little streams which trickled down the slopes. Many of these had passed their best, but *N. gloriosa*, *Ellisiana* (a deep red), *Marliacea ignea*, *M. Chromatella*, *M. flammea*, *Laydekeri*, *fulgens* and *area must*, when in full flower, be things of beauty indeed.

Even so slight a notice of this garden would do it an injustice which failed to include the rich variety and abundance of conifers and other ornamental trees and shrubs which overspread it. The number of golden varieties of all sorts of trees was conspicuous—golden Elms and Oaks, *Catalpas*, a golden *Cedrus atlantica*, golden *Deodars* and *Yews*, and though last, not least, an avenue of considerable length of the golden *Cupressus macrocarpa*, which, if winds and frosts are merciful to it, will be, perhaps, unique. Of flowering shrubs, *Olearia*

View in Lady Howard de Walden's garden at St. James's, West Malvern. From a photograph sent by Mr. A. Dean, Kingston, Surrey.

mansion at one end of it, has completed her task by the formation of a garden, which promises to become one of the most remarkable as well as most beautiful and richly equipped in England. As I have been kindly permitted to pay it several visits recently, a short account of it may interest the readers of THE GARDEN.

The garden proper—I am thinking of as much of it as is devoted to herbaceous and other hardy plants, as well as ornamental trees and shrubs, apart from the numerous glasshouses grouped on its lower limit—occupies a space running from north to south along the lower slope of the hills, and parallel to their longitudinal axis, of about half a mile in length and of an average breadth of 300 yards or 400 yards. This belt of light, yet retentive soil, interspersed with the *débris* of rocks, and scored here and there by the little chines or hollows, worn away

in a sort of mushroom form, the warm glow of the abundant blossoms delightfully tempered by the bright green foliage. At a little distance was coming into flower a large bed of *Hydrangea paniculata grandiflora*, with regard to which I may remark that, in another considerable breadth of this grand plant in a less exposed part of the garden, its growth was so luxuriant, that one single panicle of flower which I caused to be measured yielded a girth of 23 inches and a length proportionate. Not far off on the same sloping lawn was a warm, dry bank covered with the trailing Japanese Rose, *Rosa Wichuriana*, of which the peculiarly delicate scent, reaching as the plants did over a space of some score square yards, filled the air around. Of course, in a garden of this character, where some of the choicest products of modern horticultural skill and enterprise are gathered in the greatest profusion, it must be a

Haasti was in profuse blossom, and lent much brightness to the plants of darker foliage. Roses, Lilies, and Carnations were in rich luxuriance—*edu tu sans dire*. I suppose nearly a quarter of an acre was filled with the choicest Tea Roses maturing their autumn growths. *Rosa rugosa* was growing in masses with a freedom which I have never seen surpassed, many of them showing flowers of a deeper red than the ordinary form. Among the Lilies, *Lilium auratum platyphyllum* would, I think, have borne the palm for vigour. At the corner of the garden furthest from the house were large breadths, recently planted, but coming well into flower, of hardy Heaths, among which were conspicuous *Erica vagans alba* and *Calluna vulgaris* of the varieties *Alporti* and *Drummondii*. I must not close this imperfect sketch of a most interesting garden without placing on record two beds of singular gracefulness, consisting of the little-known *Watsonia iridifolia* O'Brieni, the amount of blossom on which, especially after recent rain, impressed me with its value for out-of-door summer decoration. More ordinary plants, such as the several species of *Hemerocallis* (including *H. aurantiaca major*, which seems to open its blossoms best when in vigorous growth), were everywhere *en evidence*, and of rock plants, which were in great abundance, a grand form of *Heuchera sanguinea* (the flower spikes of which were three or four times the size of the ordinary type and much brighter), *Cytisus shipkaensis*, *Gentiana septemfida*, *Lithospermum graminifolium*, *Silene acaulis grandiflora*, not to speak of a host of others, showed admirable healthfulness: while I must not omit to mention the brilliant and beautiful strain of *Dianthus Heddwigi* and the annual *Salpiglossis*. I wish it were in my power to call up to the minds of my readers by what I have written a picture which should give a hundredth part of the pleasure which I have derived from the actual sight of this remarkable garden, which is still, it must be remembered, in its *première jeunesse*.

CANONICUS.

KITCHEN GARDEN.

POTATOES.

I was much interested in Mr. Tallack's notes on Potatoes (page 303). Potatoes, probably because they are an all-the-year-round vegetable and cultivated by everyone, do not command the notice by the general reader or writers they might do. There are a great many interesting phases in their cultivation. The exhibitor, for instance, who shows collections in variety, finds a stimulant in any new variety that may be issued by trade growers, or in an older sort brought to his notice by friends. The cottager and allotment holder are equally as keen oftentimes in the matter of variety as private gardeners. Of this, ample demonstration is afforded at the summer shows, of which there are so many. Generally, too, an ideal becomes prominent; some choose a large tuber as such, others a medium sample, some prefer rounds, others kidney-shaped, and while the coloured sorts claim some adherents, others disdain all except those possessing a clear white skin. It matters nothing how handsome the Potato may be in outline, or whether it be round or kidney, coloured or white-skinned, unless it can be pronounced good after cooking, the pleasures derivable from its growth vanish, and disappointment continues day by day so long as the soapy or otherwise poor quality is presented for consumption. A very good text is furnished in Mr. Tallack's concluding paragraph, where he

says "I find that certain varieties suit certain soils, so that it is wisest in dealing with Potatoes not to be guided too much by hearsay, but to experiment for oneself." The choice of variety suited to the soil is one of the most important studies the grower can undertake, and this can only be done by experiment and close observation. It is more important to the gardener who has to provide an all-the-year-round supply. The market man finds a similar experience, compliment or condemnation meets him according to the quality of his goods, and I am fully convinced that if only a little more careful study were brought to bear on the matter better Potatoes could be had everywhere. This, as Mr. Tallack points out, can only be done by experiment, and where the home consumption is the primary object, surely this is not demanding exertion out of proportion to the needs of the case or the reputation of the garden.

When I took charge of these gardens I learnt that Potatoes for many years were bad, and the reputation became so fixed in everybody's mind that it was considered hopeless to try to get a good eating Potato. There were a great many sorts planted in small or larger quantities, and my first step was to test by cooking, and discard all that were found inferior. This was continued for three seasons, as affecting the main crop, and in the end the selection was reduced to two—Snowdrop and Beauty of Hebron. A discordant word is never heard now on their quality. The reason for this failing was that the ground was too strong through the use of manure. This may have been so as regards some kinds, but in the case of the two now largely grown it does not apply. As showing the futility of such an argument, I make a point of giving a heavier dressing of decayed manure to the principal quarter set apart for Potatoes than any other, and for two reasons. Potatoes and Brussels Sprouts share the same plot, and most gardeners admit the necessity of rich land for giving a heavy yield of sprouts in the winter, and the acquisition of over a sack of Potatoes from every perch planted at 3 feet apart demands good ground. Often the Potatoes are so strong in the haulm that the sprouts become heavily shaded in their earlier stages, but as the varieties grown mature in early summer, there is the opportunity of digging before the sprouts have suffered much, and with a yard space between each they soon make good any loss of time from this cause—at least when the weather is favourable. This year the weather has been unfavourable for both crops, the Potatoes were planted and the crop lifted without any appreciable benefit from rain. Notwithstanding this, the crop, though lighter than in other years, was very good. Mr. Tallack expresses disappointment with Snowdrop this year on account of the depreciation of crop. I should think a fresh stock of seed desirable, particularly as a change in the case of *Magnum Bismum* did so well. I do not find any loss of vitality in the variety, but I find it requires richer land than some kinds to do it full justice. For field culture I have entirely discarded it in favour of *Mainerop* and *The Bruce*. Its constitution is not strong enough for the rougher methods adopted in farm cultivation. Abundance, *Windsor Castle* and *Sutton's Seedling* are first-rate main-crop varieties in some soils, but in this garden they are useless. *Victory* was a Potato that was retained for a few seasons on account of the high quality of its tubers. It was a heavy cropper and very early to ripen.

For early digging I have not so limited a selection, it is not always such an easy matter to get

a sufficiency of stock among the first earlies, because the demand taxes the supply in the early season. The extended list, too, comes from purchases made for comparison, those which show any advance in earliness, weight of yield, or frost resistance—an important point in a first early—preponderate over those less satisfactory. *Veitch's* and *Carter's Ashleaf* are very similar in every way and are good hardy sorts. *Ringleader* is a good Potato, both in cropping and flavour. The hardiest of all in my seed-stock is a selection of the old *Ashleaf*, when *Ringleader* and others have been badly damaged by frost this suffered but very little; *Sharpe's Victor* is good in every point except hardness. This has the tenderest foliage of all I grow. *Sutton's A1* and *Harbinger* are both rounds as early as the kidney sorts just mentioned. I have not compared them together for weight of yield. The latter is the heavier cropper by quantity, but the larger size of the tubers in *A1* probably would make them equal, and the same might obtain in comparison with the kidney sorts.

Those who have been satisfied with slovenly methods have had their reward in poor crops, the bulk being more suited for seed and pig food than domestic use. In poor soil, and this indifferently cultivated, premature ripening was very general. Late sorts in August commenced to throw out a quantity of root-strings and a tendency to supertuberation, the stalks became deeply coloured, and the inexperienced persuaded themselves that the prospects for a crop had become more assuring. Others took a more serious view of the case and cut down the tops with scythe or hook, some digging at the same time to save what crop there was from being spoilt. One gardener of my acquaintance had all his main-crop lifted by the middle of August. These, however, were planted early in the season, which was all in their favour. Disease hereabouts has not been serious; indeed, in some kinds there has been none, a fortunate coincidence when the lightness of the crop, speaking generally, is taken into account. In the southern counties the drought must have been less keenly felt than in some parts, judging from the large tubers displayed in the vegetable classes at some flower shows visited. I could not refrain from an expression of surprise at the large-sized Potatoes chosen by exhibitors, especially in the collections of vegetables. A medium sample is generally accepted as being superior in every way, and certainly an otherwise artistic display of vegetables loses a point in this choice of large tubers, particularly when arranged, as some are, in a single line along the front of the other dishes. Potatoes repay as much as anything a garnishing of Parsley, and to my mind show to much greater advantage set up on a dish than arranged in single file along the front of the staging. A great many Potatoes exhibited this summer were badly scarred through the skin's contact with the hard soil, and this is especially noticeable where there is gritty matter in the ground.

Road Ashton, Wilts.

W. STRUGNELL.

Tomato Up-to-Date.—I see in the report of the meeting of the fruit committee at the Drill Hall on the 20th that this at present comparatively little-known Tomato was shown, but although pronounced of excellent quality it received no award, being considered too much like *Conference*. Doubtless from a heavy cropping and disease-resisting point of view *Up-to-Date* is unsurpassed. At *Gunton* and also at *Blickling* it is grown almost exclusively, and for market, men in the *Norwich* district grow it

largely. I should very much like Mr. Iggulden to give it a trial next season. In one garden I saw it growing by the side of Ham Green and other popular sorts, and while the latter were badly affected with disease, *Up-to-Date* was entirely free. It has retained this character now for several years.—J. C.

The value of wood ashes.—Mr. Gilman, in his recent note on the vegetable crops at Alton Towers, attributed the freedom of the Carrots and Onions from grub to the use of wood ashes when the seed was sown. In one garden where the grub was troublesome, especially amongst Carrots, I used it freely, and the attacks were greatly lessened. All the prunings of fruit trees and bushes and thinnings of shrubberies were burnt each spring, this providing a large heap of ashes, valuable for garden use in many ways. Wood ashes is also a good fertiliser, and mixed with rough leaf-mould is often better for early vegetable borders than farmyard manure. When stored in a dry place it is very useful during

of Spanish which he has had for many years. The bulbs are invariably large, shapely and well ripened, this being no doubt attributable to the extra room allowed them. A space of 2½ feet is left between the rows and several inches between each bulb, the intervening space being filled with young Strawberry plants early in August. Sun and air are thus enabled to effectually influence the crop, which ripens not only thoroughly, but early, and although the bulbs are large, they keep well. The solid root-run suits the Strawberries and retains moisture much better than newly-prepared ground.—J. C.

Tying up Lettuces.—Throughout the summer and autumn months the Cos varieties of Lettuce grown are chiefly those which fold their leaves naturally closely together and need no tying to induce hearting. Earlier in the season such sorts as the Bath Cos need tying. This is only a simple matter, but for all that some little judgment as to when and how to do it is needed. Good Lettuces may very soon be spoilt by being

over. One large growing kind had not folded in. During September and October, Cabbages from the portion that was allowed to remain sold in the same town at from 1s. to 1s. 6d. per dozen. According to present prospects green vegetables will be scarce before the spring; in fact, they now are dear in this (the west) district. The long, dry weather prevented many from planting, while those that were planted made no headway; added to this the caterpillars destroyed many a promising crop. A neighbour of mine who had a big lot of fine Cauliflowers and Brussels Sprouts told me a day or two ago they were ruined.—J. Crook.

Round Potatoes.—Although it is very difficult to determine on exhibition tables many so-called round Potatoes from kidneys, because there are so many of intermediate form, yet we have numerous really good, true rounds that merit wider cultivation and should be more largely included in collections staged for prizes. Judges should give great consideration to distinctness when dealing with collections. The new Challenge is one of the truest and handsomest of white rounds. Syon House Prolific and Windsor Castle, too, are good. Goldfinder, White Perfection, Snowball, and London Hero are very handsome rounds, and Schoolmaster is one of the best of the older ones. Satisfaction produces very handsome flattish tubers, and when not large they come in well with rounds, but if large tubers are selected, then, as a rule, they are too long. It is not difficult to find a dozen that leave no room for doubt but that they are first-class rounds and all white. Then there are some really good coloured rounds of undoubted form. There are no better reds than Reading Russet and King of the Russets; no better purples than The Dean and Purple Perfection; and no better or handsomer mottled varieties than Conference, white, blotched carmine, and Lord Tennyson, white, blotched purple.—A. D.

CLUBBING IN CABBAGES.

IN THE GARDEN (October 15) "A. K." inquires as to the cause of his Cabbages and Cauliflowers being clubbed. An answer is given under the initials "G. W.," who states that the cause of clubbing is the Cabbage fly (*Anthomyia brassicae*). Now this insect has much to answer for as regards injury to plants of the nature of Cabbages, as its grubs are very destructive to their roots, but they are not the cause of clubbing. I daresay that "G. W." may say that he always finds these grubs at the roots when they are clubbed, but that is merely accidental, so to speak, for the real cause is one of the slime fungi, which rejoices in the scientific name of *Plasmodiophora brassicae*. The life history of this fungus is a very curious one. The spores of this fungus, which have lain quiescent during the winter, in the spring swell slightly, and their contents (small masses of gelatinous substance) escape through a hole at one side. These little masses are very minute, and can only be seen under a strong microscope; they have the power of being able to move about in damp earth. If in so doing they meet with the rootlet of any plant belonging to the natural order Cruciferae they make their way into it, and by their growth cause an unnatural distention of the cells, and in course of time the root assumes the well-known form of club-root. These enlarged cells are filled with the watery gelatinous substance of the fungus. Later on some of these cells become filled with spores, and when the root decays these are set free, and when circumstances are favourable the cycle of life is begun again. These spores are, however, capable of retaining their vitality for two and even three years, so it is easily seen that one of the best means of combating this pest is by a proper rotation of crops, or, at any rate, no plants of the nature of Cabbages, Cauliflowers, or Radishes should be grown for at least two years on the ground that has borne an infested crop. It is also very essential to clear away and burn every vestige of the plants that have suffered,

Flame Flowers at St. James's, West Malvern. From a photograph sent by Mr. A. Dean. (See p. 367.)

winter for dusting amongst Cauliflowers and Lettuce plants in frames in damp or foggy weather, and in spring as a dressing for Peas when attacked by sparrows. Many plants also enjoy a percentage of wood ashes varied with the petting material. Carrot beds that are attacked by the grub (and its presence is soon detected by the drooping foliage) may be cleared by putting half a bushel each of lime and soot into 100 gallons of water, allowing it to settle, and then watering with the clear water.—NORWICH.

Fine crops of Onions.—From a foot to 15 inches is the distance commonly allowed between the rows of spring-sown Onions, but in wet, sunless seasons the growth is often very strong and sappy and the bulbs ripen indifferently. Some gardeners also think that by leaving the plants thickly, well-matured, though small bulbs are secured, but this depends very much on the season. Nowhere have I seen Onions grown better than at Gunton, Mr. Allan having a select strain

tied up when in a wet condition; therefore the afternoon of a fine dry day should if possible be chosen for the work. One often sees the ties too low down instead of as near the top of the plant as possible; consequently, though probably dry when tied up, rain-water finds its way into the centres, with the result that when cut many of the hearts are found to be quite useless. Another bad practice is that of tying up too many at one time, as, of course, the longer they are closed the more apt are the centres to go in showery weather. After a sharp winter when autumn-planted stock is none too plentiful these simple precautions are all the more necessary.—C.

Scarcity of vegetables.—It is not often we hear of abundance and scarcity of vegetables in one season. Last May I saw some nice young Cabbages which would not pay to send into the town near by, accordingly a portion of the plot was destroyed, the land being sown to Carrots. The other portion was allowed to remain and cut

and not to leave bits of old stumps, roots, &c., to rot in the ground, as is so often done. A dressing of lime (one ton per acre) is much recommended. Gas-lime is not, as it contains sulphur, which is said to be beneficial to the fungus. Farnyard manure should not be used unless it is quite certain that the crotchet that produce it have not fed on Turnips or other plants that have been attacked by this fungus, as the spores will pass unharmed through their bodies. Gardeners after working on soil that is infested should be careful to scrape their boots before going on to other ground, or they may easily infect it. G. S. S.

Pea The Michaelmas.—This new Pea will I feel sure become a standard variety when better known. Last year I found it one of the best for October gatherings. This variety is free from mildew, resists drought well, and for so late in the year the crop is very heavy and the quality excellent. The growth is bushy, and, though a 2½-foot variety, the produce on so dwarf a haulm is wonderful, the pods being produced close to the soil.—G. W.

Pea Autocrat in October.—For some years I have relied upon Autocrat for the latest supplies, and, though a 4-foot variety, it is much branched. I only give 3-foot stakes as room is a consideration, and by pinching the points of the plants I get a much better set closer to the soil. In colour this variety is not unlike Ne Plus Ultra; in fact, it may well be classed as a dwarf Ne Plus Ultra, its dwarfness making it more valuable. It is of robust habit, and one of the best kinds to resist mildew I have grown. In my opinion it is one of the best and most profitable autumn Peas anyone can grow, as there can be no question as regards its quality. It crops well, and is a continuous bearer; a great advantage. I have had good pods from the middle of September till well into October in fine weather.—S. M.

—Some few weeks back I received a note from your office respecting the best time to sow late Peas. I have enclosed a few Autocrat for your inspection. They were sown on July 4, and I commenced picking on September 27. I have a splendid lot now (October 11), and will keep on for some time if weather permits. Sutton's Deliance, May Queen, and Stratagem, sown at the same date, did not do at all well.—A. BATEMAN, *Brisworth Hall, near Northampton.*

* * With the above note was sent a lot of excellent Peas, the pods being large, beautifully green, and filled with Peas of excellent flavour.—Ed.

Tomatoes and Cucumbers in Orange boxes.—As a rule both Cucumbers and Tomatoes are grown in less bulk of compost than formerly, growers having found that, confined to a limited root run, the plants make firmer and more fruitful growth, last longer in a bearing state, and are less liable to disease. Sourness of the soil is likewise avoided, as the roots permeate it thoroughly and moderate top-dressings and assistance by fertilisers can easily be given when the plants most need it. A grower of my acquaintance in Northamptonshire plants all his Cucumbers and Tomatoes in Orange boxes, and it is astonishing what fine crops of both are secured. The roots are merely covered at first, an inch more soil being given in due time—this by the way is not of a rich character, very little better than good garden soil, yet growth is sufficiently strong until the crop is set, when feeding once in ten days commences, the manure being sprinkled over the surface and watered in. Of Tomatoes he has this year grown Chemin Rouge, Prizetaker and Masterpiece, all profitable varieties, and Up-to-Date. The last has given such satisfaction that a double quantity of plants will be grown next season. The grower in question speaks of it as a very free setter and good in every respect.—C.

Celery.—Rain has at last come in sufficient quantity to moisten the soil to a depth of 6 inches or so, and those who have refrained till now from moulding up their main crop Celery will have cause to congratulate themselves, as all that

moulded during the dry weather will be unsatisfactory. During the past few years a change has taken place in the matter of earthing-up Celery, for many of the best growers do not now hurry the work out of hand during the early part of the season, but allow their plants to make most of their growth before moulding, except for the little soil requisite to hold the leaves together in an upright position; consequently the growth made is hardy, and there is no fear of its being harmed during the winter by either frost or wet to anything like the extent which is common with that moulded up months before it is wanted or before winter sets in. Many growers, however, stick to the old ways and will have suffered more than ordinarily this year. There are so many things in favour of late moulding that one wonders how they can be overlooked. A few of the strongest are that the plants may be artificially watered all through the summer if necessary without difficulty; the blanching is better when done by soil in a damp state, and this is not possible where it is applied early, as it soon dries in a spell of dry weather and cannot again be moistened without spoiling the hearts; pithy growth may be prevented; the plants are more hardy, and, last of all, the hearts are not so liable to injury from worms or from the tiny black slugs which are great enemies to Celery after it is moulded up. I see that the Celery maggot has been very prevalent in some places; here it is no worse than usual, but it is working later in the year, and I find that the latest planted lot is attacked, a thing that seldom happens.—J. C. TALLACK.

SUCCESSIONAL BROCCOLI.

At one time gardeners found it difficult to make the latest spring Broccoli shake hands with the earliest Cauliflowers, even when the latter were planted in hand-lights in autumn and brought on under the most favourable conditions. Since the introduction, however, of such late Broccolis as Model and Late Queen the task has been rendered comparatively easy, for gardeners are often able to cut nice heads of such Cauliflowers as Early Snowball while as yet plenty of good Broccoli remains on the ground. It requires a little time for a gardener on going to a fresh district to find out the correct dates for sowing the seed of the various kinds in order to secure a regular succession, but when once this point has been mastered there is very little difficulty, provided the winter is not too severe. Few gardeners now-a-days care to plant Broccoli on freshly manured ground, although plants so treated this season will certainly have had the advantage. Plots from which early Peas, Tripoli Onions, or early Potatoes have been cleared are the best, no other preparation being necessary than merely putting the Dutch hoe through and removing any large weeds with a coarse rake. A stocky growth from the very first is necessary, not only to enable the plants to stand the frost better, but also for making laying, should it be deemed necessary during winter, more easy. The young plants should be well thinned out in the seed-beds, and thus reap the benefit of a maximum amount of fresh air.

In enumerating succession varieties, I would remark that a mistake is often made by seedsmen in cataloguing Walcheren as a Broccoli, whereas it is purely a Cauliflower, which, although most useful during October and the early part of November, is easily discoloured and spoilt by a few degrees of frost unless well protected by bending down the leaves over the heads. It is questionable if ever there will be a better variety for opening the Broccoli season than Self-protecting Autumn. It is fairly hardy, and the inside leaves folding closely over the pure white heads shield them from inclement weather. By a little arrangement this

variety can be had well into December, and if the latest to turn in are lifted and laid in in soil in a cool shed they will last in good condition for several weeks. One of the very best varieties for following on is Backhouse's Winter White. I prefer it to Snow's, as it is now difficult to obtain the latter true. One used to be able to time it to a few days, but the present-day strains often deceive, sometimes not turning in till January or later, and then very irregularly. Backhouse's is hardy, dwarf in habit, the heads being exceptionally compact and white. Where plenty of ground is at command, Penzance will also be found a good all round reliable sort. Knight's Protecting, one of the oldest and still most reliable Broccolis, comes into use at a time of year often very trying to this crop. Leamington, another old favourite, and Cooling's Matchless, a hardly superb variety, are useful for February supplies. I grew both this and Backhouse's in the midlands, and can recommend them. Veitch's Spring Broccoli is a capital variety that, in anything like a reasonable season, will not disappoint, a moderate number of plants keeping up a succession of heads of good quality for some time. Model, Late Queen, raised by the late Mr. Gilbert, and Webb's May Queen form a trio not easily surpassed for latest supplies. J. CRAWFORD.

The Queen Onion.—I fear those who grow Ailsa Craig or Record, several pounds in weight, will not have a great liking for the very small Queen, but few varieties are more useful. It is liked more than any other for pickling, and, as it is such a quick grower, one can easily have two crops in a season. Owing to its delicate flavour it is much liked for summer salads. I use it for cooking at all times of the year. I sow in February, and again early in June, bulbs from the latter sowing ripening by the early autumn. This variety has a clear silver skin; indeed, at times it is grown under the name of Silver Skin. I am now transplanting early autumn-sown plants to give bulbs next April.—G. W. S.

Cabbage Beaconsfield.—This is much later than Ellam's Dwarf Early, but a very good variety to follow it. It is a dwarf grower having a conical heart, very solid, and just the size liked in a private garden. It may well be termed a late Ellam's, and as such it will be very useful. We have room for a good maincrop variety, the early kinds soon splitting. The one named keeps solid and good a much longer time. I saw this variety when on trial in the Royal Horticultural Society's gardens, Chiswick, and determined to grow it largely. On June 14 this year it received an award at the meeting at Westminster for its fine shape and good quality. I do not think this Cabbage is yet in commerce, but it will certainly find favour when introduced.—G. W.

Spinach failing.—One often grumbles when we get a dripping late summer, but it has its advantages, as with great heat and drought combined it is a difficult matter to grow Spinach and other autumn vegetables to perfection. I never had such a poor crop of Spinach as I have at the present time. Doubtless others with a heavier soil are in a better position, but a light soil on gravel does not suit autumn Spinach in a dry season. No matter how well treated as regards food and water, the plants have up to the middle of October either remained stationary or become smaller. I got a catch-crop by sowing in pots in a cold frame kept shaded. This was planted out in the frame, the sashes being left off at night. The plants in the open may now be assisted by soot dressings, and the crop hastened by using spare hand-glasses over the strongest plants or placing frames over them.—S. H. B.

Potato Syon House Prolific.—I am pleased to see the note on this Potato by "A. W." in THE GARDEN (p. 303). A Potato that does so well in

diverse soils is an acquisition, as I note Mr. Tallack, at p. 303, writes most favourably of it, remarking that it is a splendid cropper and the quality all that can be desired. In these days it is not an easy matter to grow one variety that will do well in districts so wide apart. This seems at home in any soil, as Mr. H. C. Prinsep (p. 304) writes that Syon House Prolific has done wonderfully well this season, the tubers being large, even in size, and well flavoured. I have just lifted a very heavy crop of the above variety, and though, doubtless owing to the drought, the tubers are somewhat smaller than last year, they are quite large enough, and considering the season the yield is a very heavy one. I would strongly advise growing this variety in the open field.—F. R.

Celeries.—The very fine collection of a dozen diversely named Celeries staged the other day at the Drill Hall from Aldenham House Gardens helped to show how very little is the difference in size, earliness, or quality when culture is identical. Out of the entire number it was difficult to say that one was better than another. This fact should make writers chary of extolling one variety over another. After all, how small are the distinctions in Celeries, and how really few *bona fide* varieties are there. Tastes may differ as to colour, but with regard to quality there is, after all, little to choose. Given really good culture and exceeding care in blanching, he would be a clever man who could say of the dozen named sorts exhibited that one was superior to the others.—A. D.

HEELING IN OF BROCCOLI.

In many instances the breadths of Broccoli in gardens will no doubt hardly pay for the trouble of heeling in this season, in consequence of their having made such poor growth owing to the protracted drought of the past summer and autumn. The welcome rains have come too late, it is feared, to benefit them to any great extent unless it should be the very late varieties. There are, however, cases where the locality is naturally cool, also where the subsoil is a retentive one, in which good breadths are to be seen. Such is the case here, and although we have suffered extensively from the effects of the dry weather in a great many respects, the Broccoli crops certainly must be excepted. These have done well from the start, and from appearance a casual observer would run away with the idea that we have had plenty of rain, whereas the reverse has been the case. The piece of ground they occupy is in the lowest part of the garden, and slopes gently towards the north. The soil itself is rather a stiff loam, resting on the red clay which is found in such abundance in the adjoining fertile valley of the Frome, and beneath this is the old red sandstone. Could the drought have been foreseen, a more favourable spot could hardly have been selected for the growing of the crop. The top spit and the subsoil being heavy, it retained moisture for a great length of time and kept cool. This enabled the plants to grow away freely, and when they had developed a sufficiency of foliage the ground was shaded and thus prevented from becoming unduly dry. In some few favoured localities, protection either by heeling in or by placing straw, bracken, or dry leaves—preferably either of the two former—amongst the stems, is unnecessary. In others protection is absolutely necessary, that is if it is wished to save the plants from being injured should the winter prove at all severe. In such cases it is always best to be prepared beforehand, as we cannot foresee what kind of weather may be in store for us. The stems of Broccoli, as is so well known, are very susceptible to injury, and the most ready and efficient method of protecting them is by the process called heeling in. Owing to the climate here being naturally moist, I find it best to always heel in winter and spring Broccoli, otherwise a very large percentage would be destroyed in severe winters. Of course, where but small breadths are grown, the materials men-

tioned above may be used instead if the labour attending heeling in is objected to, but when the plants run into hundreds the latter is the more economical and satisfactory way of dealing with them. The time for doing this is now close at hand, as I think it best done early in the month of November, as the plants then have time to recover from the operation before the winter sets in. The great thing in performing the work is to open out a good trench on the north side of the break, distant a foot or 15 inches from the outside row and about the same in depth. When this is ready the plants should be tilted or heeled over into it by driving a spade down behind each, which if carefully done will ensure a good ball of soil adhering to the roots. A good layer of soil should then be placed on top of the ball and all trodden quite firm again. The stems should also be well covered with soil up to the lowermost leaves. This should be followed up row by row until the work is completed. If care is taken when heeling in the plants to see that plenty of soil remains attached to the roots they will not flag, or not to any appreciable extent, and in the course of a few weeks the leaves and remainder of the stems above ground will assume a natural position. A. W.

BOOKS.

ALPINE PLANTS IN LOWLAND GARDENS.*

THE author of this excellent work is now in charge of the botanic gardens in Zurich (Switzerland), and was formerly in the botanic gardens at Berlin, where he formed several rock gardens, and had under his care the whole of the extensive collection of mountain plants grown in these gardens. The book consists of 257 pages, and is illustrated by twenty-two large engravings and four excellent plates representing various rock gardens, including those at Abbotsbury, Newton Abbot. The object of the book is not so much a description of individual plants as a handbook on the requirements of alpine plants, the most practical methods of cultivation, &c.

The first four chapters deal with alpine plants in their native home, their geographical distribution, the influence of climate and temperature, the conditions under which alpine plants flourish, their botanical structure, &c., &c. The next six chapters are devoted to alpine plants in our gardens. Here detailed instructions are given for the culture of alpine plants under various conditions. The author enumerates the best methods for ensuring the necessary amount of humidity of soil and atmosphere, also the influence of light, the protection in winter, cultivation in pots, propagation, and the enemies of alpine plants. Here also most useful hints are given on collecting plants and their treatment on arriving in their new home to ensure acclimatisation. The third section of the book contains two well-written chapters on the construction of rockwork and on the planting of alpine gardens. This portion is particularly well illustrated, showing the wrong way as well as the right way of placing the stones, the construction of crevices with due regard to the requirements of the plants as well as the grouping for picturesque effect. Due consideration has also been given to water in connection with rocks, and much useful information is supplied concerning the treatment of the margins of ponds and streams.

The actual work of planting under various conditions is well described, and the chapter treating on this subject will be a boon to gardeners and amateurs alike, as throughout it is apparent that the author writes not from hearsay, but from practical experience. Very interesting is the fourth section of this work, which contains obser-

* Die Alpenpflanzen in der Gartencultur der Tiefländer: ein Leitfaden für Gärtner und Gartenfreunde von Erich Wöckle. Berlin, 1898. Published by Gustav Schmidt (formerly Robert Oppenheim), Berlin, S.W., 46.

vations on alpine plants when growing under the altered conditions of lowlands.

The longest and, perhaps, most important section is a list of all the best alpine and sub-alpine in cultivation. By means of short abbreviations after each name the list shows clearly whether the plant in question requires a sunny or shady position, whether it flourishes best in stony soil or in soil rich in humus, and other cultural notes, together with the native home. It must be regretted, however, that, excellent as this list is, it contains not a single descriptive note. We have, of course, many books dealing with descriptions of alpine plants, and it was, perhaps, this circumstance which caused the author to omit descriptions altogether, but I cannot help thinking that a few more abbreviated notes after each name, giving approximately the height, the time of flowering, and the colour, would have made the book still more valuable, and would have been an immense help to the amateur.

At the end of the book most useful combinations of plants are recommended for various purposes. But the chapter which will be hailed with the most genuine delight is the last one, which in a clear and explicit manner deals with plants erroneously known by other names, or which are easily mistaken for one another. The author gives in this chapter such a lucid explanation of the characteristic distinctions, that he well deserves the thanks of his readers for clearing up a great deal of misconception in the nomenclature of alpine plants.

ROSE GARDEN.

NEW ROSES OF 1897-98.

Now that the planting season is with us again, a few notes upon the new Roses that have proved good here, or been seen elsewhere in pleasing form, may not be out of place. We have such a large number sent out each season that one is puzzled which to procure. The following, so far as I have grown them, are, I think, the best. Under those for 1897 we have

COUNTESS OF CALEDON, one of the many grand additions to our Hybrid Teas, a class that I feel certain will become more popular. This is a very large and well-formed Rose, the flowers standing well after being cut. My best flowers have been upon standards. It is quite distinct and of a beautiful rich carmine shade.

DUCHESS MARIE OF RATHOR is a Tea with strong and upright growth. The shape is good and is retained for a longer time than in most Roses. The colour is creamy yellow, with a warm crimson-yellow centre—a very soft and pleasing shade and a welcome addition to the more delicately shaded Teas. It is a cross between Kaiserin A. Victoria and Dr. Grill.

EMILIE GONIN is another of M. Guillot's new Teas. It is a good grower, large, full, and one of the prettiest shaded Roses we have. The flowers are white, tinted orange-yellow, the large petals bordered with rosy carmine.

EMANUEL GERBEL is a decided advance upon Mme. Falcot in depth of colour and substance. It was a sport from the latter, and is equally free and pointed in bud.

EMPEROR A. OF RUSSIA gives us a colour found in no other Rose, a tawny copper, lake and orange being intermixed. It lasts exceptionally well and is very free-flowering. This has been good late in the season and under glass.

FRAU GEBELMAYR VON BOCH is of a stout, bushy habit. The bud is long, opening into a full flower. It is one of the most promising new Teas of the year. The colour is a creamy gold, but occasionally flushed with bright carmine on the back of its outer petals.

FERDINAND JAMIS has been good and is sure to take a prominent place, the flowers large and globular; rosy carmine, shaded with deep salmon.

GRAND DUCHESSE VICTORIA MELITA reminds one of Kaiserin Augusta Victoria, but has a distinct shade of golden yellow in the centre. It appears to be a stronger grower than Kaiserin Augusta Victoria, equally free blooming, opens well, and is in flower throughout the whole season, as might well be expected from its parentage. It is a cross between Safrano and Caroline Testout.

MME. CADEAU-RAMEY gives us yet another delicately-coloured Tea. This is rosy flesh, with yellow at base of petals and bordered with rosy carmine.

MME. LOUIS GRAVIER is really distinct and good. The growth, also size and substance of the flower, are first-rate. This is bordered with carmine, the ground colour a light salmon, tinted with orange-yellow.

MRS. FRANK CANT is the result of crossing Mme. Gabriel Luizet and Baroness Rothschild, two well-known pink Hybrid Perpetuals. The colour is a clear pink, edged with silvery white. Here we get the more perpetual-flowering properties of Baroness Rothschild and the exquisite perfume of Mme. Gabriel Luizet.

MRS. RUMSEY is a sport from Mrs. George Dickson. This is deeper in colour, a grand autumnal, and mildew-proof.

OSKAR CORDEL resembles one of its parents, Merveille de Lyon, in growth and foliage, but is a very rich bright carmine and sweetly scented.

REV. ALAN CHEALES is a peculiar Peony shaped flower, pure lake on the inner side of petals and a silvery white upon the back.

ROBERT BUNCAN has large shell-shaped petals and is of good form. A bright rosy lake may best describe this.

SOUVENIR DE JEANNE CABAUD is a copper-coloured Tea, with apricot-yellow and carmine shaded centre. It is a good grower and is sure to be an excellent garden Rose.

In 1898 we have nine varieties deserving of special mention. Of course, it is easy to miss several sterling varieties when dealing with those only seen during the present year; but some of these have been before us at exhibitions of new Roses during 1896-97.

ADINE is robust and a very free bloomer. The form and substance of blossom are good. It varies in colour, but is always pleasing; colour a deep orange, shading to rose and gold; frequently a mixture of yellow, white, and bright carmine.

ARDS ROVER will be a valuable pillar Rose, being a deep crimson, heavily shaded with maroon. This appears to be a very free bloomer.

BERYL has pleased me very much. It is free, exceptionally sweet-scented, buds long, not very full, but most showy. The colour is a deep golden-yellow, a shade we do not find in any other Rose.

GRAND DUKE ERNEST LUDWIG is the result of crossing Maréchal Niel and General Jacqueminot, and gives us what has so long been wished for, viz., a red Maréchal Niel. It is just the same in growth as the latter, with a little darker foliage, and has the colour of General Jacqueminot, with the size and substance of Maréchal Niel. In

KILLARNEY the buds are long, petals large, and the whole flower well built. A clear flesh-white, suffused with pale pink and salmon, is the colour.

INNOCENCE will take a foremost position among our pure whites. It is of vigorous and upright growth, the flowers large and globular, and borne upon stiff stems.

PURITY will probably be our best early white pillar Rose. It is of perfect form, of medium size, and lasts well both on and off the plant. It is of vigorous growth, and produces flowers from almost every eye upon the previous season's shoots.

SOUVENIR DE J. B. GUILLOT varies from a deep nasturtium yellow and red to crimson and bright copper.

WHITE MAMAN COCHET is a pure white sport from Maman Cochet, one of our best and most reliable Teas.

Suisse.

Rosa macrantha.—This is probably the most beautiful of all the light-coloured single Roses. Many of the blossoms measure as much as 4 inches in diameter and are of the most delicate blush shade. The golden stamens are also most conspicuous and numerous. Macrantha and Bardou Job are good companions and of very similar habit. The latter is well known as being the best dark-coloured single Rose. It is advisable to grow these single Roses on pillars, then their full beauty is seen.

Rose Fanny Stolwerck (Tea-scented).—This Rose has no pretensions whatever to form. It is as rough and irregular as it is possible for a Rose to be, but its colour is superb. This may perhaps be best described as old gold, heavily shaded with rosy salmon and peach. It reminds one of the old favourite, Ophir, but the blossoms are larger and there is more of the salmon tint mingled with the bronze. It should make a very telling climbing Rose if time be allowed for the plant's full development into a good specimen. Its growth is very vigorous.

Rose Dr. Rouges (Tea-scented).—This is another very attractive climbing Rose of the type of l'Idéal. The buds are almost identical in form, but they differ much in colour, being quite a rich rosy red. In the expanded flowers the colour changes to rosy pink, with a pronounced shading of bronzy yellow. A very distinct feature of this Rose is the form of the outer petals in the expanded flowers. These are of the pointed shape of the Cactus Dahlias. As this variety produces very large corymbs of blossom, this peculiarity of petal is rendered very effective.—P.

Rose Marquise Litta.—This is one of the richest coloured Hybrid Teas. It is well known that many Roses have a richer colour in autumn than they have in the summer, and in this case the beautiful vermilion shade that appears only in the centre of the first blossoms entirely suffuses those that are now produced. This Rose has splendid outer petals. Where a mass of colour is desired this beautiful Hybrid Tea would be the one to plant. There is not such a gorgeous blaze as is produced by masses of Cramoisi Supérieur, Marquise de Salisbury, and others of that type, but we have in Marquise Litta a variety that will be found useful for garden decoration and at the same time be available for cutting.

Rose Gloire des Rosomanes.—The introduction of this was of great benefit to rosarians, for it is the reputed parent of General Jacqueminot, and everyone knows this to be the best and sweetest of all red Roses. There may be some difference of opinion, however, about the General's parentage, but it is very clear that Gloire de Margottin, Bardou Job, Eugène Appert, and Géant des Batailles can claim relationship with Gloire des Rosomanes. One would have thought that even better Roses than these would ere now have resulted from this gorgeous variety. But perhaps, now that Rose growers are alive to the benefits derivable from cross-fertilisation, we shall ere long see a brilliant race arise with double flowers.—P.

The de la Grifferaie stock as a cultivated Rose.—It may not be generally known that this rampant multiflora Rose, so extensively used as a stock for climbing Tea Roses, makes an excellent decorative variety for shrubbery borders, the wild garden, railway embankments, or anywhere where a hardy, vigorous-growing kind is desired. Crimson Rambler is undoubtedly a near relative of this Rose, and they resemble each other in growth and flowering in a very marked degree. Instead, however, of the bright grass-green foliage of the popular Rambler, the de la Grifferaie has dull sage-green leaves of a woolly appearance. The huge corymbs of blossom are indeed most effective. In colour the flowers vary from deep rose to blush-pink, and it is a very peculiar and

interesting sight to see the two shades of colour blended in one corymb. The individual flowers are very small and double.

Nurserymen and the Manetti stock.—We notice this is now offered by the 20,000 to the trade, which is a sad prospect for those who deal with them. Many of the choicest Roses, if worked on the Manetti stock, hardly grow at all after the first year, but often go back, and it is one of the causes of the bad state of Rose gardens in many places. Why do people whose best interest it should be to sell only things that are satisfactory to their customers use such a stock as this? It is supposed to give a good bloom for one year in forcing, and no doubt also gives a large bloom for cutting for shows in some instances. The worst of it is that the customer cannot tell that the things are worked in this way; they are worked so low. All, therefore, who wish their Roses to live and thrive should beg nurserymen never to send them on the Manetti stock, at least so far as the more beautiful Tea Roses are concerned.—P.H.L.

Rose Valentine Altermann (Tea-scented).—We have none too many white climbing Roses that are autumn flowering; therefore every addition to their number is appreciated. There are the old favourite Aimée Vibert, in many respects unsurpassed, and also Mme. Alfred Carrière, a rampant flesh-tinted, sweet-scented white variety. Lamarque and Climbing Niphotos are lovely, but, unfortunately, very tender. In the Rose under notice we appear to have a good novelty. The flowers are very double, almost as much so as in the old dwarf variety, Marie Guillot. They are of medium size, quite globular, and if not of the snowy purity of Niphotos, yet they are of a pleasing whiteness, with just a faint tinge of carmine on the outer petals. It is said to be a cross between Mathilde Lenaerts and Sombreuil. In the smooth growths and foliage it resembles the former, and the carmine tinge of the outer petals is the same colour as in this Rose, whilst the influence of the pollen parent is very evident in the predominant white colour.

GARDEN FLORA.

PLATE 1195.

ANNUAL CENTAUREAS.

(WITH A COLOURED PLATE.*)

THANKS to the praiseworthy fashion of late years of using as far as possible only long-stemmed flowers for bouquets, the different species of Centaureas, annual as well as perennial, have become general favourites in all countries. Indeed, where cut flowers are in demand there are no better and more valuable blossoms to be found amongst the large family of composites than the five species and varieties of Sweet Sultan represented on the coloured plate. The finest and noblest of all is Centaurea Margarite, introduced by an Italian firm in 1891. It grows to a height of 1½ feet to 2 feet and produces an abundance of bloom. The flowers are large, pure white, resembling in their form the well-known yellow Sweet Sultan. They are beautifully fringed and very sweetly scented. When cut they remain in full beauty for more than a week. C. odorata is the counterpart of C. Margarite except in the purple colour, and is also very fragrant. C. suaveolens with its charming citron-yellow flowers is a general favourite for cutting, and at the same time a lovely annual for borders. C. moschata alba and C. moschata rubra are more robust and taller in growth than the three foregoing. They attain

* Drawn for THE GARDEN by Rose Pinckert in Messrs. Haage and Schmidt's nursery at Erfurt. Lithographed and printed by J. L. Goffart.

a height of 2½ feet to 3½ feet and are perfectly hardy. Their flowers are not quite so graceful, the involucre being not so well developed as those of the above-mentioned species.

The culture of Sweet Sultans is very easy. Seed may either be sown in the open ground from the end of March to May where the plants are to remain, simply thinning them out to a distance of 1½ feet to 2 feet each way, or it may be sown in a cool frame as early as possible from the middle of February to April. The seedlings must be transplanted before they produce tap-roots, from April to May. With *C. Margarita* and *C. odorata* it is essential to choose the driest and sunniest place in the garden, as they are very apt to damp off in wet seasons. HAYGE AND SCHMIDT.

Enfol.

THE WEEK'S WORK.

HARDY FRUIT.

STRAWBERRIES IN POTS.—The growth of these has now practically ceased, but, all the same, do not leave the plants to chance. Mine have just been looked through, the late runners having been taken off and the surface soil stirred a little where it was weedy or green. For the present I shall let the plants remain where they are. So far the rains have not been too excessive, nor will there be any fear of frost to injure or check the roots for at least a fortnight or three weeks. By that time it will be advisable to arrange them in their winter quarters. Three ways at least are open for doing this: they may be stored in cold frames, stacked close together in ashes on the flat, or be piled on their sides in lines or against walls. Personally I prefer the cold frames, whether they be covered with glass or mats not being of any material moment. Where this accommodation is impracticable, then the next best thing is to store the first early kinds on their sides, the later ones or batches being, if need be, left on the flat. It may be asked why any difference is thus made. The reason is that the earliest lot should not get excessively wet or be chilled by early falls of snow. In every case look well to the drainage and see that the bottoms of the pots are quite free. The system of storing, whether it be on the sides or on the flat, depends a deal upon the locality and local surroundings. If exposed, then give the plants some shelter, against walls if possible; if sheltered, storing on the flat will suffice. But if in addition the effects of fogs from our large towns, manufacturing or otherwise, are feared, then the protection of pits is at once the best choice. I do not know what the experience of other growers may have been this year, but in my case every variety except Royal Sovereign has done as well as one could possibly desire, making stout, dark green leathery foliage. Royal Sovereign, on the other hand, has been troubled with mildew, whilst the growth has not been all that one could desire. The stock of this variety was from three sources (my own and two others), but in each case the growth is not of the best. Having been hindered from preparing the ground and planting the alpine Strawberry plants the middle of last month, as alluded to early in October, I

have been forced to postpone it, but ere these lines are in print it will have been finished. I do not apprehend the slightest harm by this later planting, the alpine Strawberry being extremely hardy. In fact, if the dry weather, which held on so long in October, be taken into consideration, it only seems reasonable to think it was work very well deferred. Hints have been given as to the soil for these and its preparation. I now only add what I have actually done this past week. The ground chosen was that from which late Peas and Carnations had been taken. This was well manured with old Mushroom beds and double dug, a good dressing of soot being given; the same of lime will be added a week or two later upon the surface as a deterrent to slugs and worms. The plants are firmly planted, being lifted with large balls and afterwards watered, let the weather be what it may. My usual practice is to plant at 18 inches apart each way, but for greater convenience in picking the fruits and for weeding and stirring the soil, top-dressing, &c., I have this year missed out every fourth row; the plants will thus be in beds with an alley between them. If anyone happens to be short of seedling plants, the runners from the seedlings will be the next best choice. Otherwise if these be not wanted, they should all be cut off and cast

Centaurea moschata.

aside. The latest fruits of the alpine were this year gathered in the open on October 29; last year it was November 1 or thereabouts. Of the new St. Joseph it appears that later fruits will be obtainable in the open when the weather is mild. The best place for this variety is a south border.

FRUIT TREE PLANTING AND REARRANGING.—After the rains we have had this work should be proceeding apace so as to lose no time in completing it whilst the weather is open and favourable. Trees received from the nurseries, if packed in moist material, need not be unpacked before the positions chosen for them are quite ready, so as not to dry up the fibrous roots. If otherwise received and the roots dry, put them into wet litter at once or well moistened soil. In every case look to the roots and make clean cuts of all those needing it. Do this so that the wound faces downwards—not upwards nor sideways. The young rootlets then will have a better chance of striking away in the right direction. Do not plant deeply—no deeper, as a rule, than the trees themselves indicate. Make the soil firm around them, and if the manure be at hand, mulch them at once, that from the farmyard being the first choice. In giving first attention to newly-received

trees, do not lose sight of those which require attention at home—such, for instance, as those which have possibly been planted too closely together, to leave which in that condition is certainly not advisable. Take particular notice of any that give indications of complete exhaustion as well as those that are not fruitful. If a piece of wall can be spared for growing on young trained trees to a larger size, it is well to arrange for such, so that they may when taking their places later on be more nearly the size of the rest and not so conspicuous. Do not leave any available wall space unoccupied. Whatever the aspect may be, it may be profitably taken up. There is no reasonable excuse for neglecting this now that cordons can be had so cheaply.

VARIETIES TO PLANT.—To name such fully would no doubt be misleading, for what will thrive well in some soils and situations will not always do so in others. I will, however, offer a few names of such as I find in my own case decided acquisitions, some of which will no doubt succeed, if not all, whilst some possibly are already being grown. Of Apples, note should be made of Newton Wonder, which bids fair to be a general favourite. Bramley's Seedling is better known; this also is a hardy variety. Rivers' Codlin when better known will be more sought after, being a valuable autumn Apple. Allington Pippin promises well. With me it is on the Paradise stock and crops heavily. Belle de Boskoop will be another acquisition; it is hardy, with the quality and appearance of Reinette du Canada. As an early kind St. Edmund's Pippin deserves notice. Of Pears I have noted that Marguerite Marillat is advancing in favour. It is a handsome fruit and of excellent quality, season early in October. Beurré de Fouquieray has pleased me very much this season. It is a sweet, juicy Pear. The best results have been from a double grafted tree—*i.e.*, an old tree re-grafted. To mention Thompson's would seem to be superfluous, yet it is not any too well known, nor is Conference, which is a rich, buttery Pear. My best fruits of these varieties are from south walls. Of Cherries note should be made of Guigne d'Annonay, which with me upon a south wall is the earliest dessert variety, although closely followed by Early Rivers, which is a finer fruit and of better quality. Bigarreau de Schreken ripens about the same time as the last-named; it is of the largest size, remarkably fine in texture, and a splendid variety for travelling. Of late Cherries note should be taken of Géant de Hedelfinger and Tradescant's Late Heart, both of which are worthy of a trial for August use, if not later; these should have east or north aspects. Of the Duke Cherries, Empress Eugénie should be noted; it is earlier and a finer fruit than the old May Duke. Of Peaches much cannot be added from point of earliness; both Alexander and Waterloo are frequently disappointing. I give the first place still to Hale's Early, which is invariably good and of fine colour; for a later kind, Dr. Hogg claims notice. It is a hardy variety, setting very freely. Goshawk is another splendid Peach, and so is Dymond, which follows it in ripening. Two of the finest late Peaches are the Nectarine Peach and Osprey, which, if they do not always properly ripen, are invaluable for stewing and compotes. Of Nectarines, the earliest for outside culture is Early Rivers, and for growing in pots or in restricted borders, Cardinal is *par excellence* the first choice; note should also be taken of Dryden, which ripens in August, and Spenser, one of the finest of Nectarines, ripening the middle of September. Of Plums, no new early kind appears to stand out prominently, but where the Early Orleans Plum is a proven favourite, a trial should be made of The Czar, which surpasses it, not being so liable to crack. Of later kinds, both Grand Duke and Monarch are unmistakable acquisitions, and so is Rivers' Late Orange. Ickworth Imp'atrice, although an old variety, requires a note; it is a high-class late dessert fruit. The Transparent Gage, including the newer forms, *viz.*, Early, Golden, and Late, will do best if

grown in either limited borders or pots, being of such exuberant growth. The foregoing notes as to varieties are made after careful observation and practice, but in no case is it advisable to plant extensively of any variety, new or otherwise, until a trial has first been given, as both soil and situation will have a deal of influence in results. HORTICULTURE.

KITCHEN GARDEN.

ASPARAGUS BEDS.—Owing to the rainfall Asparagus is later in ripening than usual, but I notice many plants have ripened the seeds. It will be well to cut the growths as soon as possible, as the seedlings if allowed to remain crowd the beds. The old system of allowing the seed to fall, thinking to secure a thick plant, is wrong if fine grass is desired. Another system in Asparagus culture is to manure beds at the time of clearing away the top-growth. This is not needed, and though it is often advised for light soils, I would prefer to leave the beds fully exposed. If extra covering is needed, far better give new soil in the way of a surface-dressing of loam and such aids as burnt refuse, wood ashes, and old mortar rubble instead of manures, which keep the roots cold and very wet, causing decay of the lower portion. In heavy land the aids advised above are beneficial, because the lighter soil enables the grass to push through more readily and encourages surface roots. The plants often suffer from excessive wet if the surface roots are exposed. Old plants have a tendency to lift themselves out of the soil, and need occasional surface-dressings of good material, and in heavy land such aids as bone-meal, nitrates, or other approved fertilisers may be added in the spring before growth is active. In no case do I advise animal manures at this season. If food is necessary, one can give it in two or three months' time in a thoroughly decayed condition, and a little fine soil from the alleys spread over the manure will make the beds tidy. Owing to the drought there are a few blanks in the younger beds, and I have planted even at this late period, as now the gaps are easily seen. It is not generally known that planting can be done at most seasons, at least from now till June, and though the spring planting is much the best, at that date there is a lot of work needing attention, and at times it is overlooked. If planted now the roots should be made firm, and a thin mulch of light material placed over them. The alleys of old beds should be hoed and made neat and all weed growth cleared away. If desired, the sides of the beds may be lined out and cut down, but avoid digging or deep forking. In fairly good soil I would advise beds on the flat with no alleys or spaces between, allowing 2 feet to 3 feet between each row of plants.

MAKING NEW ASPARAGUS BEDS.—Now is a good time to make new beds. Of course much depends upon the soil. I would urge the importance of new beds in places where the soil is poor and the growths at all weak. There was at one time a great liking for salt dressings for beds at this season, but these only make matters worse. Salt is better given whilst growth is active. Recently I saw salt advised for mixing with the soil for new beds, but I do not advise it. In suitable soil good Asparagus may be grown at no great cost. Now is a good time to trench and manure the quarters for new beds, as the soil will be much improved by exposure and in better condition to sow or plant in the spring. Those who can plant in the spring will save much time. I sow every spring for this purpose. If seed is sown for permanent beds, the surface soil must be better and in a finer condition.

CARLIFLOWERS.—It is well now to prepare for the spring or earliest crop in the open. I use hand-glasses for the main lot of plants, these being placed on a warm border, sheltered if possible, by a wall or houses. I place nine plants under each glass, and early in March the four corner ones are left, the others being lifted with a trowel and planted out, these forming a succession to those under the glasses. In planting it

will be well to make the soil, as also the plants, firm. The grower for the next few months will have a lot of trouble with various pests. Slugs are most destructive, and it will be well to use soot freely. At times mildew is troublesome, and this should be checked at once. I use dry wood ashes mixed with sulphur. In an earlier note I referred to the importance of potting up a good stock of plants. These should not be left any longer, as it is well to get the roots round the sides of the pots before December. I plunge the pot plants in ashes and cover over to throw off heavy rains. Plants may, if preferred, be pricked out into a cold frame, but they do not plant out so well as from pots, as in hard weather they do not always get the necessary exposure, getting drawn and tender.

POTATOES.—I notice the earlier kinds have a tendency to grow out very badly, and this will necessitate frequent sorting over, keeping the tubers as cool as possible. I am glad to observe there is scarcely any disease. Puritan and Beauty of Hebron are excellent as regards quality this season, a dry, hot summer just suiting these kinds. This shows the necessity of growing them in well-drained soil and not under the drip of trees. I have referred to the importance of keeping all kinds of store Potatoes as cool as possible. In my opinion a clamp is preferable, as the temperature is even and growth not so quickly excited. All clamps should now be made up for the winter. Dryness is essential to good keeping, not that it is necessary to have the tubers dry when building them up, but enough covering to prevent the wet entering the clamp should be employed. Potatoes only just lifted after the heavy rainfall will need more sorting and care than those lifted earlier, as disease will have shown itself. Seed tubers of early kinds will do well stored in shallow boxes in single layers placed endways, the boxes being placed in a cool place with a free circulation of air.

BROCCOLI.—The early varieties, such as the Protecting, Michaelmas White, and Walcheren, are now turning in freely. The first-named is the earliest. Walcheren is very good for November cutting, but needs more protection than the others, as the flower is more exposed. It is a good plan to go over the quarters of the early kinds and draw the upper leaves together. This protects the heads. All later kinds are growing away freely—indeed so much, that I have hesitated to check growth by laying the plants. It will be well not to defer the laying too long, as the growth this autumn being so soft, I fear the plants will suffer badly in severe weather. Should the weather remain open, I intend doing this work towards the end of the month. In sheltered places laying may not be necessary, but in the majority of gardens it is well to do this work, as a smaller head is preferable to none, and in severe winters the exposed stem of the Broccoli is soon injured. In laying, it will be well this season to take every care of the roots, owing to the late growth, and to build up the soil well to the leafage.

LETTUCE.—With shorter days it will not be wise to defer the housing of the Lettuce sown in July or August for autumn supplies. In my case the supply is much less than usual, as I found a difficulty in getting the seeds to germinate owing to the heat and drought. All Lettuces, either Cos or Cabbage, that are nearly full grown will feel the cold more than small seedlings, especially if the plants are blanched. I would advise storing in frames, lifting with a ball, this keeping the plants fresh for weeks. Those who have cool fruit cases may store in these, as if the plants are kept dry overhead they do not harm the trees. It is a good plan to lift into shallow boxes, as these can be moved readily and are soon placed under cover in severe weather. It is now full time to plant out on warm borders, but the work has been delayed, owing to the ground being so dry. I would advise planting on a border not recently dug, making each plant firm at planting. Many may not agree with my advice as to a firm root-hold for the plants, thinking it best to give a

liberal supply of manure previous to planting. Lettuce needs ample food, but it must be borne in mind from now to March there will be little growth, and what is made should be as firm as possible to stand our variable climate. I rely upon food in the spring. This given freely in the shape of a good fertiliser or a top-dressing of fine manure will give the plants the food required at the season needed. If the seedlings are of a fair size, they may be planted in rows 12 inches apart and 6 inches to 8 inches in the row, this distance allowing the hoe to be used freely in mild weather. I make various shifts to get a supply. A couple of rows are planted at the foot of the Peach borders, and these, like those in beds, require attention to keep slugs away. I use soot freely, and in midwinter it has been necessary to place a circle of gaslime between the plants or outside of the beds. Those who have a good supply of spent Mushroom manure will find this a grand protection in severe winters. I mulch early in December with this material and lose very few plants. S. M.

NOTES ON PEAS.

I COMMENCE with sowing in orchard house the first week in January May Queen, American Wonder, and Excelsior. May Queen was the first, but Excelsior was the favourite. The first week in February I started outside with Veitch's Exonian, First Crop, which does well here; Gradus, a splendid cropper with well-filled pods; and Sutton's Selected. For second crop I sow Duke of Albany and Stratagem, and for third crop, Prolific Marrow, a great favourite; Magnum Bonum, Perfection Marrowfat, and Goldfinger, a great favourite here. Autocrat does well here for autumn use. I sow this the third week in July, and May Queen in August.—T. C. GIDLEY, *Stoodleigh Court, Tiverton, Devon.*

—As in the case of Potatoes, Peas vary wonderfully in their adaptability to different soils and situations. I sow a good dwarf early variety on a well-prepared south border respectively in November and the latter end of June, and these furnish the earliest and latest pickings. The November sowing has only failed once in sixteen years, in a winter when the glass was down to zero several nights, and the young growth just coming away from the seed was frozen through. William Hurst and Chelsea Gem are the two best early dwarfs, there being nothing to choose between them. Daisy is my best second early dwarf Pea. If only one variety could be grown this would be selected. Of taller varieties in the order of coming in my best are Springtide, Criterion, Sharpe's Queen, and Ne Plus Ultra. These are sown either on Celery ground, or, failing this, in shallow trenches with plenty of manure well dug in. Thrips and mildew late in the season are the worst enemies. For small gardens where space is limited I should recommend a January sowing of William Hurst and Daisy monthly, with after sowings of the latter until May and one of William Hurst in June.—E. BURKELL, *Charmont.*

—Great strides have been made of late in the introduction of new kinds having a dwarf habit with a distinct marrow flavour, and the cropping qualities have not been lost sight of. For the past few years I have tried most of the new varieties, and found some excellent kinds well worth noting. I am aware there is no merit in mere variety, but new kinds soon find their level, and will be grown if they suit the soil and crop well. I am not in favour of the small white Peas with a thin haulm and small leafage. They are certainly early, but they lack flavour, and cannot be termed good cropping, two essential points needed in Peas. I think any Peas with pods smaller than in Chelsea Gem not worth growing. This is not a general opinion, but I have carefully tested varieties, and see no value in small round, white, early Peas that dry up quickly if not gathered and which lack flavour. Chelsea Gem is an excellent early variety difficult to beat for crop and quality. It is equally good

for forcing and for an autumn supply. May Queen, a variety of more recent introduction, has a touch of the marrow blood, and is in my opinion a distinct gain. This is a dwarf variety. Sown in pots in frames I have gathered it early in May, and from the open ground the third week in favourable seasons. This I consider one of the best of the new types and one of the best flavoured. Bountiful is a fine Pea, and well worth noting, as it is valuable for autumn sowing. It is 3½ feet in height and most prolific. Springtide is another excellent variety for early work, and what is so necessary, it is a marrow Pea, dwarf and remarkably early, and a very heavy cropper. For June supplies I do not know of any variety superior to Gradus, a really fine Pea. At first it had a difficulty in holding its own, as some very inferior stocks were sent out, but the true Gradus is one of the best introductions of late years. Another of the newer varieties is Daisy, a second early and a good companion to Gradus. This is a splendid cropper, equally valuable for its high quality, and it appears to do well in most soils. For quality and crop one must include Veitch's Mainerop. In the same category comes the older Stratagem, difficult to beat for flavour and cropping. Autocrat is excellent, as is Peerless Marrowfat, a very fine Pea with grand quality. The old Dr. Maclean is still one of the best Peas grown. The same remark applies to Veitch's Perfection. Though this was my best variety in the midlands, I now fail to grow it well, the soil or climate not being suitable. So far no Pea is superior to Ne Plus Ultra. There are many much larger, but taking it as an all-round late Pea it is still one of the best. Many, I fear, will not agree with me as to Duke of Albany, a variety seen at all exhibitions. I fail to see its value for home supplies: the quality is inferior to that of many, and the pods, though large, are soon over. The following are my best early kinds: Chelsea Gem, Exonian, William the First, Excelsior, Springtide, Daisy, and Gradus. The best midseason kinds are Eureka, Criterion, Mainerop, Perfection and Stratagem, and for later supplies, Dr. Maclean, Autocrat, Sharpe's Queen, Thomas Laxton, Ne Plus Ultra and Michaelmas. The best time to sow for an autumn supply depends upon the soil and locality. With a heavy clay soil earlier sowing would be a necessity. In the northern parts of the country the sowing could not well be deferred till very late in June, whereas in the south nearly a month later would give a full crop. I have had Sturdy, a dwarf Ne Plus Ultra, good well into November in the north, whereas further south late Peas mildew badly and fail to crop much after September. By sowing the first earlies, such as Chelsea Gem, May Queen and Exonian, late in July I have had good crops. No matter what variety is grown late, it is in a measure a question of season, position and soil.—G. WYTHES, *Syon Gardens, Bedford.*

I find the following Peas answer in this garden, keeping up a supply from June until October, or later if autumn is good: Early kinds, Lightning, William I., and Wm. Hurst; mid-season, Duke of Albany, Autocrat, and Stratagem; autumn, Walker's Perpetual Bearer, Ne Plus Ultra, and Lightning. I sow once a fortnight, the last sowing being made about July 6.—Wm. Torry, *Belfast Castle.*

I grow Chelsea Gem and William I. Improved for early work, Chelsea Gem coming a few days earlier on the same border. The mid-season varieties are all well-known sorts, such as Duke of Albany, Telegraph, Telephone, Stratagem, and for latest Ne Plus Ultra and Downie's Amateur, a Pea which gives satisfaction at table and as a cropper.—JAMES M. REID, *Erskine, N.B.*

Peas were very late in this neighbourhood, it being June 24 before I gathered the first dish out of doors. In frames and pots under glass I have grown this year Chelsea Gem, Harbinger, Defiance, and American Wonder. These I consider first-class varieties for forcing under glass. They gave some fine dishes during May and the early days of June. For early crops out of doors

my experience and observations have led me to select Chelsea Gem, Defiance, William Hurst, and William I. out of the great multitude of early Peas so highly recommended to growers as reliable kinds for first gathering. For general or second crops, the varieties that find favour here are Abundance, Boston Unrivalled, Duke of Albany, Marvel, Stratagem, Telephone, Telegraph, The Duchess, Criterion, and Veitch's Perfection. For late crops I grow Downie's Amateur, Autocrat, and Ne Plus Ultra.—JOHN MACKINNON, *Torrighs, Dumfriesshire, N.B.*

The best Peas with me are William I., Criterion, Veitch's Mainerop (the best Pea I know), Autocrat, Chelsonian, and Ne Plus Ultra. The best early Pea is Veitch's Selected Extra Early, with William I. to follow. The best midseason is Veitch's Mainerop, and Autocrat and Chelsonian, sown here the last week in June, give a late autumn supply.—THOS. SHINGLES, *Torteworth Court, Gloucester.*

Peas do remarkably well in this garden. For the first crop I grow First Crop, Sangster's No. 1, and William I. For second and main crops I depend on Telephone, Telegraph, and Ebor. The last I think very highly of both as a cropper and for quality. I sow every fortnight from the beginning of February until June 10, the last sowing being Telephone, Telegraph, and Hundredfold. I often gather Peas until the end of October when the frost does not cut them down. I have tried a good many varieties of Peas, but find the above all that can be desired.—W. PRIEST, *Eglinton Castle, Ayr.*

My first early was May Queen, sown on the same day as Chelsea Gem (an improved Wm. Hurst). It was fit to pick six days sooner. Gradus has done well. It came in a week after Chelsea Gem. For my middle and main crop I grow nothing but Veitch's Perfection. I make four sowings, viz., at the beginning, middle of March, end of March, and second week in April. For late crops I grow Ne Plus Ultra, three sowings, viz., middle and end of April, and second week in May. For the two last sowings I make trenches as for Celery, sow the Peas, and cover with plenty of rotten manure. Last year I had lovely Peas in October from these sowings. I have tried a good many kinds of Peas, but have yet to find any equal to these.—C. FORBES, *Austey Hall, Trumpton.*

I consider the best Peas to be William I., Exonian, Duchess, Daisy, Supreme, Autocrat, and Ne Plus Ultra. I consider William I. the best early, being a week in advance of Exonian, Duchess the best midseason, and Autocrat and Ne Plus Ultra the best late Peas. The best time to sow late Peas is from the second week till the end of June. Gradus is a Pea I like, combining the pods of Duke of Albany with the earliness of Exonian.—FRANK SINGLETON, *Thornhill House, Stalbridge, Dorset.*

I find Bountiful very satisfactory for a first crop: at the same time (generally early in January) I sow Fillbasket, which follows immediately. Fillbasket may not be so sugary as one would desire, but it is a variety I cannot afford to be without, as I have to pick by the bushel at a time from a limited space, and I have yet to find so good a cropper as Fillbasket. I then sow at intervals of about eighteen days such sorts as Satisfaction and Perfection. Owing to the long spell of dry weather midseason Peas had a bad time of it: still I had good gatherings from Satisfaction and Perfection. I leave off sowing Peas after June, and the variety I finish up with is Late Queen. I find that the supply of late Peas depends much on the weather. A good midseason Pea sometimes proves of much value if sown at the same time as the usual late croppers. Whilst referring to Peas, I should like to mention a variety known as Dwarf Defiance, a small packet of which was sent me for trial. Owing to the pressure of other things the packet was overlooked until May 11, when it was sown on poor soil, and beyond giving the haulm the support of a few short sticks the Peas received no further care. However, the crop was so good, and

stood the drought better than any other, that I intend to depend on it for a large crop next year. The Peas are large and plentiful, in very handsome pods, which are easy to open.—THOS. PLUMB, *Shobdon Court, Herefordshire.*

The best early Pea for this soil and for keeping up a good supply both for quantity and quality is Dickson's Harbinger. It is, I believe, the best early Pea grown. I have sown it the same day as William I., and gathered both the same day. It is a heavy cropper, averaging eight to ten large Peas in straight pods, and of delicious quality. Gradus is one of the best 3-foot Peas grown. It is a strong grower, heavy cropper, with large pods of ten and eleven Peas of first-class quality, equal to Ne Plus Ultra. For main-crop and late use I grow Ne Plus Ultra and Autocrat. I sow about every fortnight, the last sowing about June 20. The last sowing is always worth risking. Autocrat, I think, is the better of the two for the last sowing, being a little more free from mildew.—A. GRUBB, *Appleby Hall, Atherton.*

I have grown Chelsea Gem for an early this year, and it has been very good. I have grown Gradus for second early. Duke of Albany, Criterion, and Ne Plus Ultra are very good. Walker's Perpetual Bearer, sown on June 5, is the best for late crops.—E. SIMPSON, *Wrothley, Wolverhampton.*

For early work I use Chelsea Gem and William Hurst, following with William I. One of the best I have tried for midseason work is Fertility, a grand dark green, semistar-shaped pod, well filled with Peas of good flavour. For late work I have found none to beat Autocrat and Ne Plus Ultra: the former named I prefer. Last year I sowed it the last week in June, and was picking in October.—W. FAIRBANKS, *Wynnstay, Ruabon.*

The Pea crop has been a good one. My early sorts are William I. and Ringleader. I find nothing better. I have grown the following dwarf Marrows without sticks and found them excellent: Harbinger, Sutton's Seedling Marrow, Excelsior and Early Marrowfat. They are free bearers, with large pods, well filled and of good flavour. I strongly recommend those new dwarf Marrow Peas. Other sorts requiring sticks are on an average about 3 feet high, and are Early Giant, Magnum Bonum, Veitch's Perfection and Dr. Maclean. For later use I grow Ne Plus Ultra (still one of the best in cultivation), Duchess of Edinburgh and Late Queen. My early Peas were sown in February, and I sowed the sorts named fortnightly from April to the first week in July.—JAMES TEAG, *Bearwood, Wokingham.*

The following Peas do well with me and are the best this year: Early, William Hurst and William I.; midseason, Prince of Wales, Dr. Maclean, Smith's Bountiful, Magnum Bonum and Conqueror; late, Veitch's Perfection, Autocrat and Ne Plus Ultra. I sow late Peas from the middle of May to the middle of June. After that date it is best to sow early sorts. Autocrat, sown the last week in May, is a fine Pea for gathering about the middle of August.—A. AUSTIN, *Blackmoor Park, Worcester.*

The varieties which I find to answer my purpose and keep up a supply from the last week in May to the first or second week in October inclusive are William I., William Hurst, Ringleader, Sangster's No. 1, Telephone, Duke of Albany and Alderman, a grand Pea for cropping and flavour. For succession after the three named, Dr. Maclean answers well: it is a splendid cropper. For my late crop I grow Veitch's Perfection, which I gathered last season in the last week of October. I find in this district that June 12 is late enough to sow for an autumn supply.—D. M. MCKINNON, *Elmhurst.*

Such old varieties as Veitch's Perfection and Ne Plus Ultra will take a lot of beating, both for flavour and cropping, although on the other hand we have a first-class new sort in Autocrat. The best early Peas grown by me here are Chelsea Gem, Exonian and Earliest Marrow. For mid-season, Veitch's Perfection, Magnum Bonum,

Daisy, Advancer and Prince of Wales, the last a fine cropper, but a little deficient in flavour, are the best. For late autumn use, Autoerat, Maelean's Best of All, Ne Plus Ultra, Emperor of the Marrows and Chelsonian are the best. I sow at intervals from the middle of May till the middle of June for autumn supply.—A. KEMPER, *Gosfield Hill Gardens, Halstead, Essex.*

— The best early Peas, both for cropping and flavour, are American Wonder and William I. The best Marrowfats I grow are Duke of Albany, Telegraph, Telephone, Dr. Maelean, and Ne Plus Ultra, these yielding a good supply into late in the autumn. The best time to sow for an autumn supply is not later than the first week in July or last week in June.—F. CLARKE, *Lowther Castle, Penrith.*

— The Peas I favour here are Exonian, Gradus, Duke of Albany, Chelsonian, and Autoerat. The best early Pea is Exonian, followed by Gradus; the best midseason Peas are Duke of Albany, Chelsonian, and Autoerat; the best late Pea is Autoerat. The time for sowing my latest Peas is June 12. Previous to that date I sow a row or more as soon as the previous crop is well through the ground, which means a sowing about every ten days.—F. GEISON, *Milthurst.*

— As soon as the ground is in a fit state to receive the seed, I put in a few rows of Veitch's Selected Extra Early, which I have found the best for our ground. In case this should fail, I sow the same sort again with Veitch's Early Marrow in a fortnight's time from the first sowing. This latter sort comes into use a few days later than Veitch's Selected Extra Early. These are the two best early Peas I am acquainted with, and they give me entire satisfaction. For a midseason Pea, I rely almost exclusively on Mainerop, a fine-flavoured Pea, good cropper, drought and mildew-resisting, and in every way satisfactory. For continuing the supply of Peas late into the autumn, I should confine myself to a good strain of Ne Plus Ultra. I have on several occasions gathered nice dishes of this Pea in November. The next best late Pea, as far as my experience goes, is Autoerat, which I have grown now for several years. I find the middle of June quite late enough for sowing the latest batch of Peas. Even this is sometimes a failure.—J. EASTER, *Nostell Priory Gardens.*

— I find none more satisfactory than William I., Duke of Albany, Prince of Wales, and Ne Plus Ultra. Ne Plus Ultra is hard to beat for a late supply. It should not be sown later than the first week in June in this district.—JAS. FOLKARD, *Sand Hutton, York.*

— After trying many varieties of Peas, I depend mostly on William I., The Duchess, Duke of Albany, and Ne Plus Ultra. I have grown Fertility for the first time this year, and it has proved a splendid mainerop Pea. It was awarded XXX at the Chiswick trial in 1895. I grow William I. for first crop and Ne Plus Ultra for the last. I consider this the best of all Peas, and generally sow it about the second week in June. J. TURNER, *Sydney Park, Slough.*

— The Peas mentioned below, as far as my experience goes, I consider amongst the best and most reliable: Veitch's Selected Extra Early, William I., William Hurst, Kentish Invieta, Criterion, Dr. Maelean, Prince of Wales, Veitch's Perfection, Maelean's Best of All, Ne Plus Ultra, and Autoerat. The three last-named sown at intervals during the month of June, and one of the early sorts—say William I.—sown in the first or second week in July, should ensure a good autumn supply.—S. GRAY, *Rhyddel Court, Worcester.*

— I find American Wonder the best early Pea. Being dwarf, it can be sown under a wall or in any warm corner, to be followed by William I. and Exonian in the open ground. For second early I grow Champion of England and Huntingdonian with Veitch's Perfection; and for late crops, Autoerat, British Queen and Ne Plus Ultra. Of the above-named kinds I grow the largest bulk of William I. for the early crop, Champion of England and Huntingdonian for

second or main crop, and Ne Plus Ultra for late, as I find it withstands the mildew better than any other variety. As I require a large quantity of Peas, I find it best to grow the older, hardier, and tried sorts. But for special dishes some of the newer varieties are better, being superior in size, but I cannot say that they are so in flavour or cropping. Pea-growing is in many cases a question of sticks, and where good, tall, bushy sticks are not obtainable I should advise growing the dwarfier kinds, as dwarf varieties well supported would be more productive than tall ones falling about in every direction.—GEO. GRIFFIN, *Stebch Park, Harrogate.*

— I consider Boston Unrivalled, Champion of England, Chelsea Gem, Gradus, Ne Plus Ultra, Autoerat, and Sharpe's Queen the best for cropping and flavour. The best early kind is Chelsea Gem; the best midseason, Boston Unrivalled, Autoerat, and Gradus; and the best late, Sharpe's Queen, Ne Plus Ultra, and Walker's Perpetual. I find nothing gives so good results as sowing at two different times, namely, end of May, and

Unrivalled is proving an excellent variety with me.—WM. McDOWALL, *Breckin Castle Gardens, Forfarshire.*

— The best Peas here are May Queen, Veitch's Perfection, Sharpe's Queen, Eureka, Duke of Albany, and Ne Plus Ultra. The best early kinds are May Queen, Chelsea Gem, and William I. The best midseason are Veitch's Perfection, Duke of Albany, Eureka, Sharpe's Queen, and Ne Plus Ultra. The best for autumn use are Ne Plus Ultra, Veitch's Perfection, and Eureka. The best time to sow for autumn use is the first week in June.—WM. CHESTER, *Chatsworth.*

— I find Earliest Marrow, Peerless, Ne Plus Ultra, Gradus, Criterion, Exonian, Mainerop, and Veitch's Perfection excellent varieties to grow, as they combine good flavour with heavy cropping. Earliest Marrow is a very excellent kind. It comes in very early, is of medium height, a heavy cropper, and of excellent flavour. For early work I grow Chelsea Gem for the first and Sutton's Marrowfat Seedling, a large Pea of good quality—both of these being dwarf kinds:

Hydrangea paniculata grandiflora at St. James's, West Malvern. From a photograph sent by Mr. A. Dean. (See p. 367.)

again about June 10 or June 12. By sowing at these times I usually am able to obtain a regular supply till the frost comes.—J. CROOK, *Forde Abbey, Chard.*

— The six best Peas I consider, taking into account cropping and flavour, are William I., Exonian, Duke of Albany, Gladiator, Champion of England, and Ne Plus Ultra. The best early is William I.; midseason, Duke of Albany; late varieties for autumn bearing, Autoerat and Ne Plus Ultra. The best time to sow Peas for an autumn supply in this district is the first week in June.—H. BERRY, *Ashby St. Legers, Rugby.*

— The Peas I find suitable for keeping up a supply during the season are Sangster's No. 1, A1, and Early Giant, for early use; for midseason, Boston Unrivalled, Stratagem, Telephone, Duke of York, and Duke of Albany; for autumn supply, Sturdy, Late Queen, and Latest of All. By sowing Latest of All about May 20 and the other two varieties, with Duke of Albany, ten days later, I have a supply till frost comes. Duke of Albany I consider one of the best Peas, and Boston

then for taller kinds in the open, Extra Early is the first, Exonian, Gradus, and Earliest Marrow coming in about the same time, but if I grew only one very early kind it would be Chelsea Gem. As a midseason Pea, Veitch's Perfection is still hard to beat. Criterion is excellent for flavour, but too soon over. For larger kinds, Mainerop, Early Giant, Peerless, and a good selection of Ne Plus Ultra are among the best and most useful. For late purposes, Autoerat I find the best, together with Chelsonian, a fine variety, and Late Queen for a dwarf. The best time to sow must be decided by the locality and soil. I sow as late as the middle of July, but the middle of June will suit most places. I sometimes sow Chelsea Gem and Extra Early late in July, and get a few good pickings from them, but all depends on the season.—J. HILL, *Babraham, Cambridge.*

— Chelsea Gem is the finest early variety that I have grown. Exonian comes in immediately after, and is an excellent sort. For a maincrop, Veitch's Mainerop and Duke of Albany are

hard to beat. Autocrat is my favourite late sort; the pods are of good size, the Peas of excellent quality, and it seldom grows over 4 feet in height. The most suitable time to make the last sowing of Peas is between May 20 and May 25 in this part of the country.—JAMES NICOL, *Hornby Castle, Bolah.*

—The best Peas, in my opinion, both for cropping and good flavour are Duke of Albany and No Plus Ultra. William I. I consider to be the best early Pea for all purposes. The two above-named I consider the best for mid season, with Gladiator and Stratagem for the late autumn supply. I find that Peas sown about the first week in June give the best results for autumn cropping in this district.—E. GILMAN, *Alton Towers Gardens, Stoke-on-Trent.*

ORCHIDS.

DENDROCHILUMS.

The Dutch botanist Blume established this genus a good many years ago upon a species probably not now in cultivation, and afterwards added to it the kinds mentioned below. These have been separated by more modern botanists, but the old name dies hard, and *Platylinis*—the newer one—comes slowly into garden use. These are pretty plants when well cultivated, and there are few more handsome objects than a plant, say, of *D. filiforme* or *D. glumaceum* with fifty or a hundred of the thread-like racemes of golden or whitish blossoms hanging in rich profusion. Like many other fine plants they are too often judged by the size of the individual blossom instead of taking a well-cultivated specimen as a whole. All are pseudo-bulbous epiphytes, the bulbs small, bearing usually a single deep green leaf and terminal flower-spike. They are natives of some of the warmest regions, and consequently their culture should not be attempted unless a nice warmth can be maintained in summer and winter. They are grown, in fact, in what is termed the East India house, but, unlike many of the *Dendrobes* and other occupants of this structure, they are frequently growing during the greater part of the year, and therefore must not be subjected to resting conditions, such as a cool and dry atmosphere. This, with one of the species at least, *D. Cobbianum*, is needed in late spring, but even this kind is variable in its season, and to be at all successful with them growers must be on the alert and treat them as they need. For instance, take a plant flowering now from half-formed growths, the spike appearing of course in the centre of the sheathing bract-like processes that eventually form at the base of the bulb. No one with a spark of common sense would think of drying off a plant like this, but would rather place it in the warmest house and endeavour to make the best of an unpleasant season for Orchid growth. Again, in spring as long as the growths keep dormant there is no need of undue excitement, but when seen to be on the move, encourage them by all reasonable means.

The manner of flowering makes baskets or suspended pans the best receptacles for the plants, for though the spikes are not exactly pendulous, they have when so grown a pretty arching effect that would be lost were the plants cultivated in pots on the stage. For compost the usual peat and Sphagnum mixture does well, and the drainage should have especial attention. Cover the crocks with a little rough Moss and allow plenty of crocks or charcoal to keep the compost open. Firm it well and see that the plants cannot possibly

shift about, the best position being one only slightly raised above the rim. They are true epiphytes, but if raised very high a difficulty is sometimes found, especially by amateur growers, in fixing them. The best time, as a rule, to renew the compost is as soon as the flowers have fallen, for the growths are then partly formed, but have not begun to root much, if any. The new roots when produced have, therefore, the benefit of the new material, and given hot weather, so that a stimulating temperature can be kept up, the growths advance rapidly. In a high temperature atmospheric moisture is, of course, quite a necessity, and under these conditions *Dendrochilums* revel. Not only this, but thrips, their worst of all insect enemies, are very uncomfortable and as a rule not troublesome. It is when a plant or two is kept growing slowly in an unsuitable house, where alternations of heat and cold, drought and moisture are frequent, that these busy little insects get their chance. Regarding root moisture, this must be abundant as long as the growth is moving, giving enough at all other times to prevent shrivelling. The best known kinds are—

D. COBBIANUM, an autumn-flowering species of much value. The spikes rise from small conical bulbs and are upwards of a foot in length, the flowers pale yellow with a deeper lip. It comes from the Philippine Islands, where Messrs. Low and Co.'s collector found it some twenty years ago. It is named after Mr. W. Cobb, of Sydenham.

D. FILIFORME is a delightful species also from the Philippines. The little flowers are of a golden-yellow tint. They have been not inaptly likened to gold filigree chains, and one seeing the plant in flower for the first time is charmed with it. Its flowering season is June and July, and it is one of the introductions of the indefatigable collector Cuming, who found and sent it home to Messrs. Loddiges in 1837.
